37. **Hexamethylenamin for Scarlatinal Nephritis.**—Preisich has tested the method of Widowitz, which consists in the administration of from 0.05 gm. to 0.5 gm. of hexamethylenamin and in 9.16 per cent. of those receiving the drug. The weeks of scarlet fever, with a view to the prevention of nephritis. He administered the drug in 600 cases and compares the results with those observed in 600 other cases similarly treated, except that they did not receive the drug. Nephritis occurred in 13.6 per cent. of the cases without hexamethylenamin and in 9.16 per cent. of those receiving the drug. The course of nephritis was more favorable with the hexamethylenamin than without it. He estimates that under favorable circumstances it is capable of reducing the occurrence of nephritis in scarlet fever by 56 per cent.

38. **Work as a Therapeutic Measure.**—Veraguth emphasizes the psychical origin of neuroses in general and the trend of neurotherapy toward a pure psychotherapy. Of the various forms of psychotherapy, aside from a certain element of confidence which must enter into all treatment, the so-called

"logical" method depends very largely on the physician's personality and the authority which he derives from experience and reputation. The influence of this method is limited by the short time during which the physician can impress himself on the individual patient. In prescribed occupation, the psychotherapist has a powerful aid in controling the mental influences which operate on the patient. Veraguth divides the various occupations which have therapeutic value into the following classes: 1. Work expending muscular energy, of a productive character, such as cabinet-making or gardening. 2. Work of an intellectual character, such as art, literature or science. 3. Work expending muscular energy but unproductive, such as the different sports. 4. Varied employment. As an exercise in art, drawing has obvious advantages as securing better observation and furnishing a pleasant and unusual exercise of the power of expression. Plaster or clay modeling and wood carving have similar advantages. In literary work, productive writing is more efficient than reading. A good suggestion for elderly patients is the recording of their experiences for the benefit of their friends or descendants. Neurasthenia produced by overwork at a monotonous occupation offers the best field for successful occupation therapy. Occupation therapy does not replace the other forms of psychotherapy, especially suggestion, but helps this as well as every other rational treatment. Systematic indications for different kinds of occupation are adaptability to the nature and stage of the disease and to the idiosyncracies of the patients. The greater the variety of work afforded the better. The patient must not be forced but persuaded to work, if he does not himself comprehend its sanitary value. The physician must directly or indirectly control the patient so as to determine exactly the duration of work and rest. He must exhibit a decided personal interest in the work of the patient. Occupation therapy may act by directing the activity of the senses, as in drawing; by physical exercise, as in fencing; by its psychical relief, as in writing memoirs; by strengthening the will; by overcoming the prejudice against work, and especially by diverting the mind from a tendency to become self-centered.

42. **Diabetes.**—Naunyn remarks that diabetes mellitus generally develops in patients with a congenital predisposition, frequently inherited. Cases in which it affects perfectly normal individuals are very rare. The consequence is that not much can be expected from treatment after the disease is once well established in the predisposed patients. It may be improved, but as the tendency persists it is impossible to cure it completely. It is also important to be on the lookout for the initial manifestations in individuals known to be predisposed to this disease. In every disturbance of health in a member of a family in which cases of diabetes have occurred, the urine should be tested as a routine measure, especially in persons inclined to be corpulent, children in particular and, above all, in individuals in whom a tendency to obesity develops suddenly. Even if there be no signs of diabetes, such persons should be supervised with especial care, and physical and intellectual work should be fostered and overeating forbidden. Sweets and beer should be forbidden. Milk, green vegetables and fruits (except the very sweet ones) should be recommended in moderation. Naunyn gives rules for regulating the diet after diabetes is once established, guiding it by the tolerance of the patient determined by continuous oversight of the urine. He has found the occasional interposition of a "hunger day" very useful, allowing nothing but tea and bouillon for twenty-four hours. The effect is remarkable sometimes, but not until the sugar has been reduced to a minimum of a few grams. It then not only banishes the sugar altogether, but raises the limits of tolerance thereafter. A course of dietetic treatment according to his rules requires about two months. Whether such a course can be successfully conducted at home depends on the housewife. In testing the urine he always adds Gerhardt's iron chlorid test for acetic acid. If the reaction is positive acidosis exists, and from 10 to 15 gm. of sodium bicarbonate should be given daily without interfering with the other remedial measures. If the positive reaction grows more and more pronounced, the bicarbonate should be pushed, the patient limited to fruits, milk and bread, and the continuance of the treatment entrusted to a specialist. In regard to special "cures," plums, milk, potato and oatmeal cures, he thinks that their success is due to the fact that so large a proportion of the substance ingested passes through the system unutilized. The "cure" is practically an underfeeding. The apparent tolerance is merely that comparatively little of the diet is assimilated.

51. **Spirochetes in Syphilis.**—Fraenkel's findings corroborated those of the discoverers of the *Spirochæte pallida*. He found it constantly in syphilitic lesions, but never in those of other nature.

53. **Castration in Mammary Cancer.**—Michels records his favorable experiences with oöphorectomy in mammary cancer. He reports three cases in which this operation was performed with good results. The mortality of operations for removal of sound ovaries is small. In 102 cases of which he has cognizance only 6 of the patients succumbed, 3 from exhaustion, 2 from embolism of the lungs and 1 in a maniacal attack.

61. **Apparatus for Lavage of Intestines in Children.** A tray with open slats is placed slanting in the child's bathtub, which is supplied with a drain tube and faucet at the foot. Fromm has found this arrangement very convenient for office work. In case he has to use the tub again before there is a chance to clean it, a disinfectant solution is poured over the sides of the tub and the tray, and towels laid over the sides and tray protect the next child against infection from his predecessors.

ercises are used to suggest a strengthening of the limbs, especially the feet, and emphasis is laid on every sign of improvement. A generous diet, largely milk, is administered. By this method five patients were permanently cured.

29. *Tuberculosis of Mesenteric Glands in Children.*—*Hecht* relies for diagnosis of tuberculosis of the mesenteric glands on the history, on the tenderness of the abdomen, on the abdominal pains present on both sides, and on the occasional presence of a palpable tumor or tumors. The feces often show the presence of mucus, blood and tubercle bacilli in cases in which there is no diarrhea. The prognosis is by no means hopeless, but treatment must be prolonged, lasting months or even years. If practicable, sea bathing is advisable.

30. **Varicose Ulcers.**—Loele advises the ambulant treatment of leg ulcers because the patients, who usually belong to the lower classes, will not lie abed or enter a hospital while the ulcer is of a size to be easily curable. He uses a modification of Jessner's method, which consists of cleansing the ulcer and its neighborhood with benzine, dusting it with an antiseptic powder and covering it with oiled silk. A roller bandage of cotton 20 cm. wide is then applied over the whole lower third of the leg, including the ankle and the ulcer. Over this an elastic bandage is carefully applied. If applied with sufficient firmness a new dressing need not be applied oftener than once a week. With this treatment an ulcer the size of a dollar should heal in about six weeks.

31. **Treatment of Erysipelas with Crede's Ointment.**—In cases of erysipelas at points where compression by adhesive plaster or collodion can not be applied, as on the neck or chest, Born recommends applying Credé's ointment around the affected area, rubbing the ointment into the tissues with the fingers. The rubbing must be continued on the same part of the skin for thirty minutes, and must be carefully done to avoid hurting the patient. It is repeated on three successive days, and when properly done has been uniformly successful in limiting the spread of the disease. It acts by introducing into the subcutaneous connective tissue enough silver to act as a bactericide in this encircling zone.

32. *External Temperature in Diabetes.*—*According to* Lüthje's experiments, external cold increases the decomposition of albumin and excretion of sugar in diabetic dogs, with retention of nitrogen. The external temperature should be more carefully regarded in experimental research in diabetes, and failure to do this probably explains some of the discrepancies in the published results. Observations on 4 diabetics from a month to six weeks showed analogous fluctuations in the excretion of sugar, the amount increasing at low temperatures (15 C.) and diminishing at high temperatures. The increase of tolerance thus obtained may be of the greatest practical importance.

33. **Alternating Currents in Treatment of Heart Affections.**—Laqueur has experimented to determine the action of alternating currents (sinusoidal) on the size of the heart, with the result that, with the exception of a case of neurasthenia of the heart complicated with slight dilatation, alternating currents brought about no immediate change in the size of the heart. Permanent diminution in size occurs only occasionally, when dilatation is caused by relaxation, but not when compensating dilatation in case of valvular defect is combined with hypertrophy. Increase of blood pressure is usual but not constant. In contrast to other authors, Laqueur does not consider alternating currents necessarily contraindicated in heart diseases with increased blood pressure. Slowing of the pulse is still less constant, and is probably attributable to the effect of rest. Subjective symptoms, however, are often much improved. Relief of dyspepsia, increase of appetite and better sleep are noticed. The author agrees with Lippert that the chief action of sinusoidal currents consists in the increase of blood pressure, often accompanied by diminution of frequency of the pulse in the energetic stimulation of metabolism, promotion of sleep and increase of the motor energy of the heart and of the other muscles of the body. The indications for this treatment are weakness with dilatation of the heart caused by relaxation of the heart muscle, fatty heart, idiopathic hypertrophy of the heart, and also incipient disease of the myocardium and incipient arteriosclerosis. The author does not agree with Zimmermann. In pronounced arteriosclerosis with increased blood pressure the application of this current is contraindicated as well as in aneurism. For these conditions carbonated baths are preferable. General neurasthenics are not improved, but cases of neurasthenic cardiac weakness without marked general symptoms do well. It is better than Faradism because of its greater uniformity of current. The author prefers the full bath to local applications, but describes an apparatus for local application which he has found to exert a good influence on the heart. The action of alternating currents is twofold: On the one hand the current causes an irritation of the sensory nerves of the skin and by reflex action elicits better heart innervation (increase of blood pressure, more powerful contraction of the heart, and slowing of the pulse). On the other hand, the peculiar muscular contractions which the current elicits exert a certain favorable influence on the circulation. The alternating current baths fail, however, to dilate the blood vessels like the carbonated baths. A current bath is always more of a heart-stimulating than a heart-sparing procedure.

35. **Spastic Constipation.**—Albu emphasizes the fact that the treatment of spastic constipation must be based on an exact knowledge of the character of the affection and of the condition of the patient. As spasm is developed on an atonic basis, everything favoring its development must be avoided, especially massage and cathartics. Treatment must be directed to allaying irritation and should include warm, hot or carbonated baths, hot abdominal compresses, warm oil enemata (250 c.cm. every evening), atropin or belladonna suppositories, and a generous diet, largely vegetable, free from all substances (hulls, seeds, etc.) that might irritate the intestine, prepared so as to be capable of very fine subdivision (bread from very fine wheat flour, vegetables in form of purée, cooked fruits, soups, milk, etc.). Alcohol, spices, cabbage, cucumbers, lettuce, cheese, etc., should be avoided. A further important measure is the daily introduction of well oiled bougies for from 5 to 10 cm. into the rectum, allowing them to remain from ten to fifteen minutes. Rest in bed is to be recommended only in case of much reduced patients, as it tends to increase the atony of the bowel. A Weir Mitchell cure in some cases, however, gives remarkably good results.

36. **The Bicycle in Treatment of Sexual Neurasthenia.**—Fürbinger recommends the bicycle as a healthful exercise in the open air which insures good circulation and sufficient use of the muscles without exhaustion, and rests the brain and nervous system while using the organs of special sense. In sexual neurasthenia impotence is likely to be favorably influenced by the general tonic influence of the sport. Exceptions occur which must be individually treated. Seminal losses are variably affected. A large number of patients are made worse, and these should avoid the wheel. Others are favorably influenced, and in the majority of cases no fear need be entertained that cyclotherapy will originate seminal losses. The prescription of this form of exercise should be in the hands of a physician who is a bicycler himself, and can give suitable advice as to the length of ride, kind of saddle, etc.

37. *Hexamethylenamin for Scarlatinal Nephritis.*—Preisich has tested the method of Widowitz, which consists in the administration of from 0.05 gm. to 0.5 gm. of hexamethylenamin and in 9.16 per cent. of those receiving the drug. The weeks of scarlet fever, with a view to the prevention of nephritis. He administered the drug in 600 cases and compares the results with those observed in 600 other cases similarly treated, except that they did not receive the drug. Nephritis occurred in 13.6 per cent. of the cases without hexamethylenamin and in 9.16 per cent. of those receiving the drug. The course of nephritis was more favorable with the hexamethylenamin than without it. He estimates that under favorable circumstances it is capable of reducing the occurrence of nephritis in scarlet fever by 56 per cent.

38. **Work as a Therapeutic Measure.**—Veraguth emphasizes the psychical origin of neuroses in general and the trend of neurotherapy toward a pure psychotherapy. Of the various forms of psychotherapy, aside from a certain element of confidence which must enter into all treatment, *the so-called*

"logical" method depends very largely on the physician's personality and the authority which he derives from experience and reputation. The influence of this method is limited by the short time during which the physician can impress himself on the individual patient. In prescribed occupation, the psychotherapist has a powerful aid in controling the mental influences which operate on the patient. Veraguth divides the various occupations which have therapeutic value into the following classes: 1. Work expending muscular energy, of a productive character, such as cabinet-making or gardening. 2. Work of an intellectual character, such as art, literature or science. 3. Work expending muscular energy but unproductive, such as the different sports. 4. Varied employment. As an exercise in art, drawing has obvious advantages as securing better observation and furnishing a pleasant and unusual exercise of the power of expression. Plaster or clay modeling and wood carving have similar advantages. In literary work, productive writing is more efficient than reading. A good suggestion for elderly patients is the recording of their experiences for the benefit of their friends or descendants. 71. **Buttermilk in Infant Feeding.**—Massanek has been much pleased with the results of buttermilk in feeding the sick infants in his service. All thrived on it remarkably well, as also healthy children. He gives the details of study of the metabolism in a number of the children taking the buttermilk.

74. **Chorea Minor.**—The conclusions from a study of 96 cases are that there is evidently a close connection between acute articular rheumatism, endocarditis and chorea. The combination was apparent in more than 62 per cent. of the cases described. The attack of rheumatism may run an almost latent course, but its effects on the heart become manifest later.

75. **Marrow Cells in Blood of Children.**—The conclusions of Zelenski's work are, in effect, that the presence of marrow cells in the blood of children is not so significant as formerly imagined. They do not have the same diagnostic importance in children as in adults. When nucleated red corpuscles are found in large numbers, especially megaloblasts and giant forms, this indicates a morbid process in the blood at any age, although experience has failed to demonstrate the existence of the so-called infantile pseudoleukemic anemia as a separate entity.

79. **Boric Acid Treatment of Varicose Ulcers.**—Marchetti has been much gratified by the success of the Scott Schley method of treating varicose ulcers and granulating surfaces, which he has used in 23 cases. Finely pulverized boric acid is scattered copiously over the surface, covered with four thicknesses of fine rubber tissue, extending from 2 to 5 cm. beyond the lesion, and fastened in place with adhesive plaster. Gauze is applied over this and the dressings are left undisturbed for from five days to a week or more. All the extensive lesions healed rapidly, the longest time required being twenty-seven days, in one case of extensive septic ulceration of the leg, with general symptoms. The average for the other cases was from fifteen to twenty days. These results in dispensary patients were truly surprising as such cases are apt to be tedious even with intelligent co-operation on the part of the patient, which can not always be anticipated.

81. **Staphylococci Latent in the Blood.**—Panichi reports two cases from Tizzoni's clinic at Bologna in which a furuncle or phlegmon was followed by the constant finding of the *Staphylococcus pyogenes albus* in the blood during several weeks and months after the individuals were apparently in the best of health. One patient was a gardener of 44 and the other a girl of 16. The latter presented a subcutaneous abscess in the nipple region a few weeks after a diffuse eczema, during which the staphylococcus first had been noted in the blood.

82. **Mental Disturbances and Ear Affections.**—Grazzi read this communication before the Fifth International Congress of Psychology last April at Rome. He has had occasion to observe a number of cases in which mental disturbances occurred in the course of ear affections. Diffuse otosclerosis seems to be most dangerous in this respect. Treatment of the ear affection is liable to improve or to cure the other disturbances, hence the necessity for frequent inspection of the ear by otologists in cases of neuropathy in which the physician has reason to suspect the existence of some ear trouble.

87. **Minute Sterilization of Catheter.**—Ingianni puts the catheter in a urine glass test-tube filled with a saturated solution of sodium sulphate. The tube is lengthened by slipping over it a rubber tube about 30 cm. long by 15 mm. in circumference. A cork with a hole through it and a groove along the side is used to plug the top of the rubber tube. The tube is then held over the flame of an alcohol lamp, and as the water boils in the test-tube the catheter is thoroughly sterilized in a minute or so. The catheter need not extend down to the bottom of the straight test-tube, and the pliant rubber fits its curve without trouble. Tests of catheters thus sterilized by the boiling sodium sulphate and the steam have shown that the results are perfect. If metal catheters are to be sterilized water alone or with sodium carbonate is preferable.

91. **Intravenous Injection of Oxygen.**—Sciallero describes with illustrations a simplified technic for injecting oxygen into the veins. The procedure is so simple that it brings within the reach of everyone, he says, this heroic therapeutic measure which promises good results.

92. **Chemical Tests of Stomach Functions.**—Wagner gives the results of examination of the stomach contents in 430 cases, considered in four classes: 1, Diseases in general; 2, organic diseases of stomach; 3, functional stomach diseases; 4, blood diseases. A larger number of men than women were affected with hyperchlorhydria. The large total of cases in which acidity may be classed as normal is especially important, as it amounted to fully one-half. His investigation of patients with ulcer showed 54 per cent. women and 46 per cent. men. Contrary to the rule of Riegel, Wagner found that hyperchlorhydria was present in less than half of the cases of ulcer. Nearly 25 per cent. of all the patients with hyperchlorhydria were affected with ulcer. For a certain diagnosis of ulcer it is sometimes necessary to introduce the stomach tube, and, if done carefully, this can be accomplished with little danger. In order to determine whether free blood be present in the stomach, a test lavage is given by pouring 100 c.cm. of water down the tube as soon as it reaches the middle of the esophagus, the tube being then pushed in without fear and the water removed. Occasionally retching occurs, with a flow of blood, in which case the tube should be immediately removed and the diagnosis considered established. This accident seldom gives rise to any serious consequences. The guaiac test for blood is not only somewhat too delicate for clinical use, but also gives the same results when pus, bile or saliva are mixed with the fluid to be tested, as is often the

case with stomach contents. In spite of this it is a great help in the diagnosis of gastric ulcer and of carcinoma of the esophagus or cardiostenosis, when the stomach contents can not be obtained, or in controlling the progress of healing in case of ulcer. The author found no free HCl in 90 per cent. of his cases of carcinoma. Discovery of blood in the feces of carcinoma patients seems to be of little value, since it was found in but two out of six cases in which the diagnosis of cancer had been definitely established by other means. He divides achylia gastrica into simple and complex, the latter occurring in patients with pernicious anemia. Another blood disease commonly associated with hyperacidity is chlorosis, which is accompanied by an abnormal appetite. Five out of 14 cases were found to have hyperchlorhydria. Wagner concludes that it is difficult to fix a rule for the condition of the stomach contents in certain diseases, but that there are general characteristics which are an important help in diagnosis. The cases in which the proportions of acid are characteristic are few and comprise only organic stomach diseases, namely, ulcer and carcinoma, and blood diseases.

93. **Infusoria as Parasites in Human Digestive Canal.**—Koslowsky mentions 105 cases of *Balantidium coli*, and believes that more occur than are generally recognized owing to the facts that helminthiasis from the feces are so seldom examined, that the parasites decompose readily, and that numbers of cases have not been published. Reports show that this condition usually appears as a complication, especially of intestinal diseases. At the autopsy in 30 and on microscopic examination of the tissues in 9 cases, the pathologic changes were most pronounced in, and generally confined to, the rectum and large intestines. The process was generally limited to catarrh. Long continuance of the affection may cause ulcers reaching through the mucous membrane to the submucosa or muscularis; by confluence these ulcers may attain a diameter of 3 to 4 cm. The parasite was found in all layers of the mucous membrane, even in the lumen of the small veins, but most frequently in the submucosa. His experiments on rabbits and guinea-pigs showed no evidence of infection and pigs could not be infected. He describes his methods of fixing and staining, and the development, degeneration and death of the *Balantidium coli*. He states that it can live in the dead body from ten to seventy-two hours. The embryos may be mistaken for the eggs of *Bothriocephalus latus*. He also mentions two other kinds of ciliated parasites which have been found in the human intestine.

94. **Ankylostomiasis in Japan.**—Inouye states that ankylostomiasis is found in all parts of Japan, most commonly among farmers, since human excrements are used in fertilizing and insufficient care is taken in preparing food. More men than women are affected. The malady begins gradually and may be latent as long as three months. Its severity depends on the number of worms, their length of stay in the intestine, and the resisting power of the patient. The victims are at first affected with vague digestive disturbances, become pale, complain of palpitations, lack of breath, dropsy, anemia and finally die. The local symptoms are pressure and fullness in the epigastrium, intestinal pain, heartburn, nausea and vomiting. The author found no blood or worms in the vomitus, stomatitis is rare, there is increase of saliva, foul breath, solid stools and occasionally diarrhea. The eggs found in the stools by microscopic examination have bright shells and brownish grooved kernels. He does not regard Charcot's crystals in the feces as pathognomonic for ankylostomiasis since they occur with other parasites and are not always present with this worm. The appetite is generally good, but parorexia is often present, the patient wanting peculiar things to eat (pepper, vinegar, raw rice, charcoal, tobacco, plaster or nails). Geophagia was observed only once. Parorexia is proportionate to the grade of anemia. The author finds, in contradistinction to Tanaka, that when the affection is complicated with carcinoma there is less free HCl and the lactic acid reaction is very distinct. Liver enlargement is frequent. It is difficult to decide whether splenic enlargement is due to the worms or to complicating disease. Inouye attributes a diagnostic significance to eosinophilia. He notes the changes in the nails as characteristic. They become yellowish, brittle, parchment-like and tear easily lengthwise. The surface shows wavy projections and furrows and the nails curve backward. These changes disappear with the expulsion of the worm, and they are proportional to the anemia. Various nervous symptoms and even epileptic attacks are liable to occur. He found the knee-jerk normal. He holds that the anemia can not be explained simply as a result of hemorrhage, and with many other Japanese authors adheres to the toxic theory of anemia. The following precautions should be taken for prophylaxis: Disinfection of feces with milk of lime, careful disinfection of materials used as fertilizers, avoidance of raw vegetables in the diet or of eating with soiled hands in the fields, or drinking polluted water. Two remedies are recommended for the expulsion of the worm: Oil of male fern and thymol. The first should be administered with the following precautions. The dose must not exceed 5 gm.; castor oil must not be given with the fern oil, and the latter should not be given for several days in succession. Ankylostomiasis must always be treated in a hospital, and as soon as the patient complains of pain in the eyes, disturbances of vision or dilatation of the pupils, the treatment must be suspended. He thinks that thymol is to be preferred and recommends it in doses of from 2 to 3 gm. (grs. xxx to xlv) on an empty stomach, followed after some hours by a cathartic (castor oil); this treatment is repeated daily until all worms have been expelled. Symptoms of poisoning which occasionally arise usually disappear when the treatment is temporarily suspended, fail to reappear when it is recommenced. The thymol treatment is often somewhat dangerous in advanced cases because of the temporary increase of debility.

95. **Albumosuria.**—Ury and Lilienthal have examined 40 cases of carcinoma for albumosuria and conclude as follows: 1. Two-thirds of all cases of carcinoma show a positive albumose reaction in the urine, although it varies greatly at different times in the same case. 2. Albumosuria is occasionally found in rare cases of benign stomach or intestinal affections. 3. Maixner's theory that albumose is generated in the intestines seems quite improbable. It probably originates in the tissues. Albumosuria may be absent, however, in far advanced, decomposing cases of carcinoma. 4. The discovery of albumose in the urine has no positive significance for diagnosis of cancer of the intestinal tract, but repeated positive results may confirm the presence of malignant disease. 5. Albumosuria frequently appears to be present in febrile cases.

96. **Pathogenesis of Colic.**—Nothnagel discusses the views of Meltzer, Wilms and Lennander in regard to colic, and concludes that the original term colic, should be retained for intestinal pain of a special kind in relation to its pathogenesis and clinical form. This pain arises in the intestine itself. A tetanic contraction of the intestinal musculature is effective as a primary factor in its origin. This contraction leads to ischemia, or even anemia, of the intestinal wall, by pressure on the blood vessels and thus produces the pain. How far this theory of colic may be applied to other organs provided with smooth muscular fiber is not discussed, but the author believes it to be true in regard to colic of the bladder.

97. **Dangerous Complications in Starvation Treatment of Peptic Ulcer.**—Reichmann calls attention to two dangerous complications in the treatment of peptic gastric ulcer: Loss of strength and disturbance of the heart's action which may necessitate abandonment of the treatment, and purulent parotitis, of which he has seen three cases during twelve years, one of which terminated fatally. The probable cause is the entrance of bacteria from the mouth into the parotid ducts. This is due to lack of mastication, which prevents the flow of saliva and cleansing of the mucous membrane and ducts. This complication can be prevented by applying a 4 per cent. solution of boric acid with a swab to the surface of the mucous membrane, especially that of the cheeks. The starvation treatment need not be abandoned because of these dangers, as with care these complications can be avoided.

The lighting of hospitals, however, can not be governed by any one hard and fast rule. We can always stand safely on the decision that sunlight and brilliant, diffused daylight are curative agents of the first rank, demanding free admission through generous window space to the wards of a hospital, and general wards should be as well lighted as any school room, so that physicians and nurses shall at all times be able to see their patients even from a distance and to observe minutely the color and texture of the skin and the expression of the face and be able to read in all parts of the ward the labels on boxes and bottles and the scale of the thermometer. There often arises, on the other hand, the urgent necessity for the exclusion of all or part of the light. There should be provided for all medical, surgical and neurologic wards small wards or rooms which can be partially or totally darkened, for

electric light, I exclude daylight altogether—even on bright days—and employ electricity exclusively.

A much more difficult problem than the admission of light is the induction of air into a building. To give you something of an idea of what an important question this is both from the standpoint of mechanical engineering and of administrative expense, let me rehearse to you a few figures from the calculations of one of our foremost experts on ventilation. After quoting the results of Pettenkofer's experiments on respiration, he says: "Able authorities are of the opinion that when the CO_2 is maintained at 2/10000 in excess of what is found in the outer air, that it (the ventilation) is at least good; in which case there will have to be admitted 3,000 cubic feet of fresh air per person per hour while in repose, 4,500 cubic feet for persons at gentle exercise, and 9,000 cubic feet for persons at hard work." This certainly seems to be a liberal standard to maintain, and the best authorities now seem to think it is ample in cold climates in winter, as the cost of ventilation must enter into the question, particularly when a great number of persons have to be provided for in comparatively restricted space, such as hospitals, schools, etc. It is customary in hospitals to provide for a minimum admission of 3,000 cubic feet of air per bed per hour, with mechanical means of increasing the admission to 6,000 cubic feet of air per bed per hour when it is deemed necessary. This amount of air seems to cover the contingencies and insure a standard in which the excess CO_2 will be about 2/10000.

Address

STUDIES OF SCHOOL AND HOSPITAL HYGIENE OF INTEREST TO THE OPHTHALMIC SURGEON.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON OPHTHALMOLOGY, AT THE FIFTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, PORTLAND, ORE., JULY 11-14, 1905.

CHRISTIAN R. HOLMES, M.D.

CINCINNATI.

It is, perhaps, unnecessary to remind the members of this Association of the amazing expansion of all human activities in this country in the past few years. The increase in population, the activities of the new centers of industry, and the awakening of the older and more settled parts of the country are little short of the marvellous. Hand in hand with industrial development and the pursuit of pleasure have gone the humanitarian and the scientific spirit, and we find that a very respectable proportion of our efforts of to-day are given to the building of new schools, colleges and hospitals. As a people we are slowly awakening to the importance of properly lighting, heating and ventilating these new buildings in accordance with scientific laws.

We no longer take old buildings and try to remodel them so as to make them resemble what a school, college or hospital should be, but every community that realizes the necessity for new institutions of this character is making an earnest effort to have them constructed on the latest and most approved principles and is installing in them new devices for making them convenient for the purposes for which they are built and comfortable and sanitary for the human beings who are to live or to work in them.

The object of and the justification for the modern refinement of specialization is to promote efficiency. Schools, colleges, hospitals and asylums are becoming specialized. It is obvious that for the highest efficiency in its own particular line each of this class of buildings must have its own peculiarities of construction and equipment. This subject is so varied and vast that in a brief paper like this I can do no more than merely call your attention to a few points of importance relating to light, heat and ventilation.

The sanitarian, of course, includes in his province a multitude of subjects, but we can consider that our greatest concern is with the three subjects just mentioned. The problem of the lighting of school houses is comparatively an easy matter. A law has been laid down that we all recognize as one that can not be broken without disaster to the children's eyes. It is well expressed by Dr. Risley in one clear-cut sentence: "It is the duty of the architect to secure in his plan all the window surface possible consistent with safety of construction."

Cohn places the proportion of this window surface to floor space at not less than thirty square inches of glass to each square foot of floor space, or about one to five: but the effort should always be made to exceed this proportion, and, indeed, we are told of one instance in which the proportion is one to one. Again, for obvious reasons, it is perfectly evident from what direction the light should fall on the desks of the pupils—they should face a blank wall of neutral tint, and abundant light should be admitted from the left or left and rear, so that the writing hand should cast no shadows on the writing surface. This is the law of the school house, and it is for us to express ourselves so unequivocally and so constantly that neither the architects nor school committees will dare to violate it.

We have to-day in the United States about 16,000,000 pupils in the various schools and colleges. It is unfortunately a well-known fact that a fairly large percentage of these begin to deteriorate physically soon after entering school life, and a certain proportion of these are brought to the notice of the oculist on account of a progressive myopia. Out of 30,095 children examined in the schools of Cleveland in 1899-1900, 20 per cent. were found to have defective sight, and in Indianapolis out of 25,696 pupils examined 8,166, or 32 per cent. were trying to do school work with defective vision. Of course, only a portion of these were myopes, and we never have attained, and probably never will attain, the unfavorable figures of the German schools, which, according to their own scientists, were largely due to the use of the old "black letter" type; but, while it is possible that prolonged use of the eyes in study even under favorable conditions of light and good hygienic surroundings would produce a certain amount of myopia in some subjects, yet there is not the slightest doubt but that poor light, improperly proportioned desks and seats, resulting in faulty positions of the pupil and lowered vitality because of impure air due to faulty ventilation, are the agents most responsible for the large percentage of the myopia that we find in America to-day.

I heartily agree with Dr. Risley in his proposal that our schools should introduce a modified curriculum adapted to the physical capabilities of those scholars whose eyes may be defective or who may otherwise be in feeble health. Their hours of eye and brain work should be cut down or so distributed through the day or interspersed with hours of exercise and recreation as not to become a strain that a weak eye or a weak body would feel as a burden. For this reason also competitive examinations for this class of pupils—if not for all classes—should be abolished, and the scholar should be graded by the efficiency of his daily work, and not by the results attained by excessive and prolonged work at annual or semi-annual intervals. Injury to the eyes and to the general health is, unfortunately, a not infrequent result of this "cramming for examination"

101. **Diplobacillus Conjunctivitis.**—Lundsgaard describes the course of this conjunctivitis, which seems to be quite prevalent in Denmark. It is usually suggested by the characteristic redness of the caruncle and the margins of the eyelids, but bacteriologic examination is necessary for differentiation from ordinary epiphora or phlyctenular conjunctivitis, which it is liable to simulate at times. A 2.5 per cent. solution of zinc sulphate generally cures, but some cases do better with a zinc salve or yellow ointment.

104. **Milk Diet in Tropical Diarrhea.**—Vogelius treated a patient who had just returned from the tropics with obstinate diarrhea by putting him on a strict milk diet after failure of other attempts to disinfect the intestines. Less than a quart was allowed at first and he rapidly improved, taking two quarts and then three quarts a day, gradually resuming a mixed diet as health returned.

105. **Infantile Marasmus.**—Bloch relates the particulars of 3 more cases of general atrophy in children, which, added to those he has previously reported, makes 6 cases. In 3 cases he noted during life and at the autopsy evidences of gastric hypochylia and in the 3 others evidences of pancreatic achylia. The secreting cells of the pancreas were found empty in some of the cases; in others Lieberkühns glands were unmistakably defective. In the former group, the symptoms during life had suggested insufficiency of the pancreas. The article is accompanied by two plates and the various pathologic anatomic findings are described in detail.

106. **Chronic Parotitis.**—Lendorf reports 2 cases in which a supposed tumor in the parotid gland was found on exploratory incision to be a chronic interstitial inflammation. No calculi were found in Steno's duct nor stenosis, and the inflammation subsided under local measures—extirpation of the circumscribed mass in one case and mere fomentations in the other, with potassium iodid internally. A few similar cases are on record. Chronic parotitis may be of toxic origin, or due to syphilis, tuberculosis or actinomycosis, or secondary to calculi, sialorrhea, or a foreign body, or it may be apparently primary, as in the cases related, and may simulate a tumor.

109. **Extra Systole.**—Bing describes 4 cases of this affection in which it was the only sign of heart affection. It was probably of nervous origin in one case and secondary to diphtheria in the others.

111. **Indications and Contraindications for Nephrectomy.**—This article was read by Rovsing to open the discussion on this subject at the German Congress of Surgery last April. It is based on his experiences with 112 nephrectomies. Since 1901 the mortality in 33 cases in which the kidney had been removed on account of tuberculosis was only 3 per cent.; in 13 malignant tumors the mortality was zero, as also in 5 of hydronephrosis and pyelonephritis. In 7 cases of pyonephrosis the mortality amounted to 14.2 per cent. The mortality for these groups in the nine years before 1901 had been respectively 14.2 per cent. in 14 cases of tuberculosis and 27 per cent. in 18 malignant tumors. He thinks that the assumption, when the proportion of urea is very small, is not justified by the facts. He performed nephrectomy—notwithstanding the very low proportion of urea—in 31 out of his 112 nephrectomies, and only two of the patients succumbed to anuria. The findings with cryoscopy were frequently misleading. In 12 out of the 50 cases in which he tested the freezing point the findings were absolutely false in 12 instances, as for example, normal values with unmistakable Bright's disease. He does not accept cryoscopy, the phloridzin test nor determination of the proportion of urea as very accurate tests of kidney functioning, the last named being the most reliable. Catheterization of the ureters, with bacteriologic and chemical tests of the urine affords valuable information. If he finds bacteria, albumin and pus in the urine from the other kidney he waits until these are cured before removing its mate. But if albumin alone is found, then he performs nephrectomy, convinced that the albuminuria is of toxic origin, regardless of whether this assumption is confirmed by the freezing point or phloridzin tests or not.

112. **Manual Compression of Aorta for Postpartum Hemorrhage.**—Suber's experiences with 6 cases and another observed in Bissmark's care, has convinced him of the great efficacy of this means of arresting or preventing hemorrhage. He thinks it should be adopted as a routine measure in all severe or dangerous hemorrhages and when there is uncertainty in regard to the cause of the hemorrhage. Also in case of intervention liable to be accompanied by hemorrhage, especially when there has been much loss of blood previously. A further indication is to gain time for aseptic and rational measures to arrest the hemorrhage in some other way. It is also indicated when the uterus reacts feebly or not at all to mechanical procedures, and when the circumstances forbid further loss of blood. It also renders it possible to postpone an intervention until conditions are more favorable for its success. He adds that compression of the aorta is liable to prove extremely important also in hemorrhage from inversion or rupture of the uterus or from abortion or mole.

119. **Surgical Treatment of Pericarditis with Effusion.**—Sjövall's communication may be summarized in the advice to operate at once in every case of pericarditis with effusion, not suppurative. The intervention should be pericardotomy, preferably Ollier's technic. The accumulation of the effusion impedes the action of the heart, and its removal is a necessity, as he shows by relating his experience with two patients, each 16 years old, both restored to health by simple pericardotomy. In one pericarditis had followed acute articular rheumatism.

Address

STUDIES OF SCHOOL AND HOSPITAL HYGIENE OF INTEREST TO THE OPHTHALMIC SURGEON.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON OPHTHALMOLOGY, AT THE FIFTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, PORTLAND, ORE., JULY 11-14, 1905.

CHRISTIAN R. HOLMES, M.D.
CINCINNATI.

It is, perhaps, unnecessary to remind the members of this Association of the amazing expansion of all human activities in this country in the past few years. The increase in population, the activities of the new centers of industry, and the awakening of the older and more settled parts of the country are little short of the marvellous. Hand in hand with industrial development and the pursuit of pleasure have gone the humanitarian and the scientific spirit, and we find that a very respectable proportion of our efforts of to-day are given to the building of new schools, colleges and hospitals. As a people we are slowly awakening to the importance of properly lighting, heating and ventilating these new buildings in accordance with scientific laws.

We no longer take old buildings and try to remodel them so as to make them resemble what a school, college or hospital should be, but every community that realizes the necessity for new institutions of this character is making an earnest effort to have them constructed on the latest and most approved principles and is installing in them new devices for making them convenient for the purposes for which they are built and comfortable and sanitary for the human beings who are to live or to work in them.

The object of and the justification for the modern refinement of specialization is to promote efficiency. Schools, colleges, hospitals and asylums are becoming specialized. It is obvious that for the highest efficiency in its own particular line each of this class of buildings must have its own peculiarities of construction and equipment. This subject is so varied and vast that in a brief paper like this I can do no more than merely call your attention to a few points of importance relating to light, heat and ventilation.

The sanitarian, of course, includes in his province a multitude of subjects, but we can consider that our greatest concern is with the three subjects just mentioned. The problem of the lighting of school houses is comparatively an easy matter. A law has been laid down that we all recognize as one that can not be broken without disaster to the children's eyes. It is well expressed by Dr. Risley in one clear-cut sentence: "It is the duty of the architect to secure in his plan all the window surface possible consistent with safety of construction."

Cohn places the proportion of this window surface to floor space at not less than thirty square inches of glass to each square foot of floor space, or about one to five; but the effort should always be made to exceed this proportion, and, indeed, we are told of one instance in which the proportion is one to one. Again, for obvious reasons, it is perfectly evident from what direction the light should fall on the desks of the pupils—they should face a blank wall of neutral tint, and abundant light should be admitted from the left or left and rear, so that the writing hand should cast no shadows on the writing surface. This is the law of the school house, and it is for us to express ourselves so unequivocally and so constantly that neither the architects nor school committees will dare to violate it.

We have to-day in the United States about 16,000,000 pupils in the various schools and colleges. It is unfortunately a well-known fact that a fairly large percentage of these begin to deteriorate physically soon after entering school life, and a certain proportion of these are brought to the notice of the oculist on account of a progressive myopia. Out of 30,095 children examined in the schools of Cleveland in 1899-1900, 20 per cent. were found to have defective sight, and in Indianapolis out of 25,696 pupils examined 8,166, or 32 per cent. were trying to do school work with defective vision. Of course, only a portion of these were myopes, and we never have attained, and probably never will attain, the unfavorable figures of the German schools, which, according to their own scientists, were largely due to the use of the old "black letter" type; but, while it is possible that prolonged use of the eyes in study even under favorable conditions of light and good hygienic surroundings would produce a certain amount of myopia in some subjects, yet there is not the slightest doubt but that poor light, improperly proportioned desks and seats, resulting in faulty positions of the pupil and lowered vitality because of impure air due to faulty ventilation, are the agents most responsible for the large percentage of the myopia that we find in America to-day.

I heartily agree with Dr. Risley in his proposal that our schools should introduce a modified curriculum adapted to the physical capabilities of those scholars whose eyes may be defective or who may otherwise be in feeble health. Their hours of eye and brain work should be cut down or so distributed through the day or interspersed with hours of exercise and recreation as not to become a strain that a weak eye or a weak body would feel as a burden. For this reason also competitive examinations for this class of pupils—if not for all classes—should be abolished, and the scholar should be graded by the efficiency of his daily work, and not by the results attained by excessive and prolonged work at annual or semi-annual intervals. Injury to the eyes and to the general health is, unfortunately, a not infrequent result of this "cramming for examination."

The lighting of hospitals, however, can not be governed by any one hard and fast rule. We can always stand safely on the decision that sunlight and brilliant, diffused daylight are curative agents of the first rank, demanding free admission through generous window space to the wards of a hospital, and general wards should be as well lighted as any school room, so that physicians and nurses shall at all times be able to see their patients even from a distance and to observe minutely the color and texture of the skin and the expression of the face and be able to read in all parts of the ward the labels on boxes and bottles and the scale of the thermometer. There often arises, on the other hand, the urgent necessity for the exclusion of all or part of the light. There should be provided for all medical, surgical and neurologic wards small wards or rooms which can be partially or totally darkened, for light is a stimulus and conditions not infrequently arise, e. g., lead encephalopathy, traumatic meningitis and chorea major, in which all external stimuli must be reduced to the minimum. In ophthalmology, of course, this is of paramount importance. The eye is the terminal of one of the largest, most sensitive and most important nerves in the body, and its whole mechanism, nervous, vascular and muscular, responds with the greatest sensitiveness and delicacy to the stimulus of light. In almost all conditions of irritation or inflammation, therefore, we must be able to temper or banish the light at will.

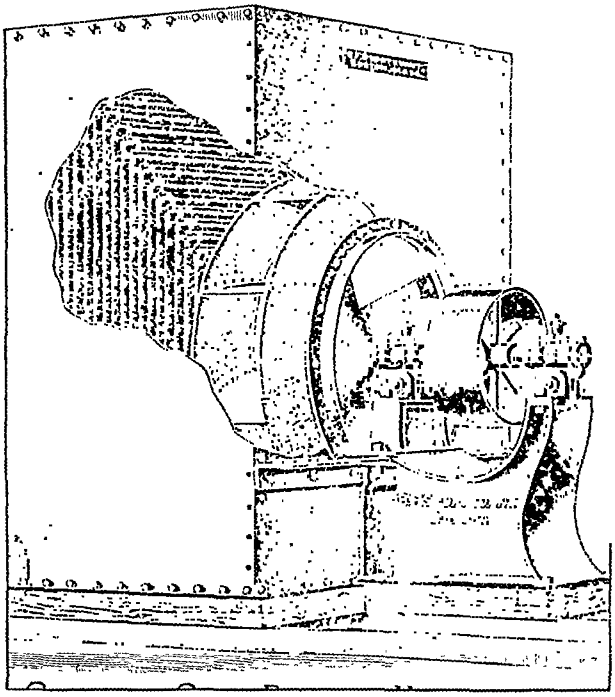

Figure 1.

In this connection it is necessary to consider the question of artificial light. This is not difficult as far as the operating room is concerned. In my own operating room, I have found it necessary to adopt the incandescent electric light as a permanent source of illumination. In the midst of a great manufacturing city where bituminous coal is universally used it is impossible to depend on the varying quality and quantity of daylight, so that, now being thoroughly familiar with the appearance and colors of tissues under the electric light, I exclude daylight altogether—even on bright days—and employ electricity exclusively.

A much more difficult problem than the admission of light is the induction of air into a building. To give you something of an idea of what an important question this is both from the standpoint of mechanical engineering and of administrative expense, let me rehearse to you a few figures from the calculations of one of our foremost experts on ventilation. After quoting the results of Pettenkofer's experiments on respiration, he says: "Able authorities are of the opinion that when the CO_2 is maintained at 2/10000 in excess of what is found in the outer air, that it (the ventilation) is at least good; in which case there will have to be admitted 3,000 cubic feet of fresh air per person per hour while in repose, 4,500 cubic feet for persons at gentle exercise, and 9,000 cubic feet for persons at hard work." This certainly seems to be a liberal standard to maintain, and the best authorities now seem to think it is ample in cold climates in winter, as the cost of ventilation must enter into the question, particularly when a great number of persons have to be provided for in comparatively restricted space, such as hospitals, schools, etc. It is customary in hospitals to provide for a minimum admission of 3,000 cubic feet of air per bed per hour, with mechanical means of increasing the admission to 6,000 cubic feet of air per bed per hour when it is deemed necessary. This amount of air seems to cover the contingencies and insure a standard in which the excess CO_2 will be about 2/10000.

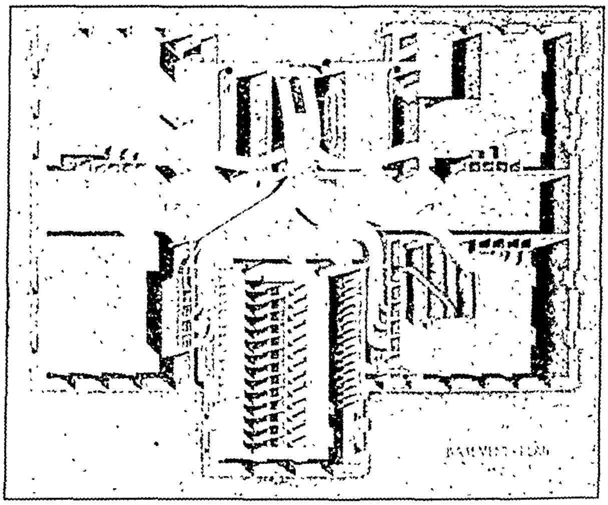

Figure 2.

In passing, I would beg to remind you that the amount of carbonic acid present in the atmosphere may be readily ascertained to a sufficiently close degree for practical purposes in the following manner: Six clean, dry and well-stoppered bottles of a capacity, respectively, of 100, 200, 250, 300, 350 and 400 c.c., a glass tube containing exactly 15 c.c. to a given mark and a bottle of perfectly clear, fresh lime water constitute the apparatus required. The bottles should be filled by means of a hand ball syringe with the atmosphere to be examined. Add to the smallest bottle 15 c.c. of the lime water, put in the cork and shake well. If turbidity appears, the amount of CO_2 will be at least 16 parts in 10,000. If no turbidity appears treat the bottle of 200 c.c. in the same manner. Turbidity in this would indicate 12 parts in 10,000. In similar manner turbidity in the 250 c.c. bottle indicates at least 10 parts in 10,000; in the 300 c.c., 8 parts; in the 350, 7 parts, and in the 400, less than 6 parts.

Taking this minimum of 3,000 cubic feet of fresh air per hour per bed and applying it to a 36-bed ward of a hospital we will find that we will need to pass through the ward 108,000 feet of air every hour and 2,592,000 every twenty-four hours. Now, as to the cost of this. The engineer quoted above says: "With coal at $5 a ton of 2,000 pounds (a fair average for the whole United States), it will require 20 cents per hour for fuel to maintain the warmth of every one million cubic feet of air passed through a building, taking one day with another throughout the winter. In the case of hospitals in which the heating is to be maintained day and night, say, through 180 days of a year, the fuel for the same time will be $864 for every 1,000,000 cubic feet of air passed in an hour throughout the season. This, of course, does not include interest on the plant, labor, service, etc., which increases it to about $2,000 per season per million cubic feet of fresh air passed into the building every hour. As the plant grows larger this can be reduced to probably $1,500 per year for each additional million cubic feet of air admitted per hour. This estimate will be considerably modified in the case of schools, as, of course, schools are not run continually. The fuel cost per hour, however, will remain about the same (20 cents for each million cubic feet of air passed through the building). An eight-room school will require about 1,000,000 cubic feet per hour during sessions, for all purposes, increasing at about the ratio of 100,000 cubic feet of air per room as the school building becomes larger.

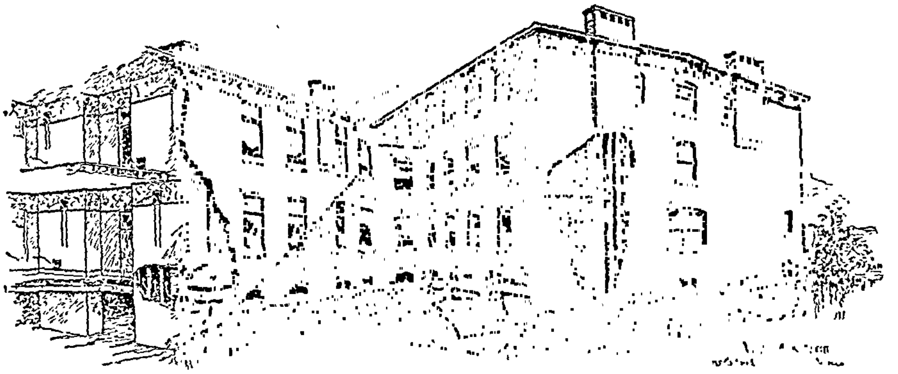

Figure 3.*

For the purpose of ready comparison of the hospital and school-house problem, I might say that the school room as now designed is about 24 by 32 feet and intended for the accommodation of from 40 to 50 pupils. You will see, therefore, that under what is known as the Massachusetts standard, which provides for the admission of 1,800 cubic feet of air per hour per child in the schools (without regard to weight), the amount of air necessary for admission to the average school room per hour should be about 100,000 feet. The Massachusetts standard was formerly much higher than this, but it was found that to make all the existing buildings comply with the proper standard would necessitate the practical reconstruction of every building devoted to school purposes in the state, so that the commonwealth had to make a compromise between its conscience and its pocket book, reduce its requirements and impose only such conditions as what is known as a "reasonable economy" would allow. As we build in the future let us be more generous both with money and air space.

It is hardly necessary to argue to this body of surgeons that generous ventilation of hospitals is necessary—in fact, indispensable—but such a striking illustration of this fact has lately come to my attention, confirming previous experiences of my own both in my own hospital and in the Municipal Hospital of Cincinnati, that I can not forbear to mention it to you. Dr. E. C. Rosenow[1] made an exhaustive and painstaking report on "Streptococci in Air of Hospital Operating Rooms and Wards During an Epidemic of Tonsillitis," and by microscopic examinations and culture experiments by the method of exposed plates demonstrated the existence of the same organisms in the tonsils of those attacked by the angina in the air of the wards and operating rooms and in the infected peritoneal cavities of women who had been subjected to laparotomy during the progress of the epidemic. Dr. Rosenow's paper is well worth the careful perusual of all of us who work in or have to do with the construction and management of hospitals. Broadly speaking, there are two principal methods of ventilation in use in hospitals and schools. One of these is the aspiration system, in which the vitiated air is sucked out of the building through vents which are warmed sufficiently to create a draught out of each room or ward through them, the aspirated air being replaced in the building by fresh air which is brought in through ducts and warmed or not by steam or hot water radiators, as may be required by the season.

The other system is that of the "blower" or "forced draught" system, which is divided into the "exhaust method," where a fan is employed to exhaust the air from the building, and the "plenum method," where a fan is employed to drive the air into the building. It will be observed that the principles of the "exhaust method" and of the "aspiration system" are the same, except that the means for aspirating the air from the building are in one case thermal and in the other mechanical.

We will, therefore, take up first a system that is now being installed in a very large number of our schools, libraries, churches, factories, and theaters throughout the country, observe with some minuteness its method, and then consider the theoretical and practical objections to its use. The name of the system, "plenum"—meaning full—implies that the air of the ventilated building is to be kept somewhat under pressure—that the air is to be forced through. A large open window or air intake is left in the wall of the building, the fresh air enters here, is caught by the fan, which is the mechanical factor of the "draught" system, and is blown across a system of heaters and water pans (Fig. 1) and thence into a system of flues or heaters which carry this warmed and moistened air to the various rooms of the

---

* Fig. 3.—Waltham Hospital, showing shafts in the walls and heaters and vents in the wards. "The wing on the right in the illustration is divided into numerous small wards and nurses' rooms so that the method of distribution becomes similar to that provided for an office building or dwelling. Owing to the fact that the building is of so-called mill construction with no heavy internal partition walls, it was necessary to supply practically all of the fresh air and to remove the foul air through flues built into the exterior brick walls. The general arrangement of these flues on one end of the building is indicated. In the other wing are located two wards, one on either floor, and both of considerable size. These are heated from overhead outlets, as indicated. The air is forced toward the end of the room farthest from these outlets, being generally diffused in its passage and finally escaping through registers at floor level and nearly beneath the supply openings. In more complicated arrangements, and particularly in contagious wards, the system may be arranged to furnish practically every bed with an independent supply."

[1] American Journal of Obstetrics, December, 1904.

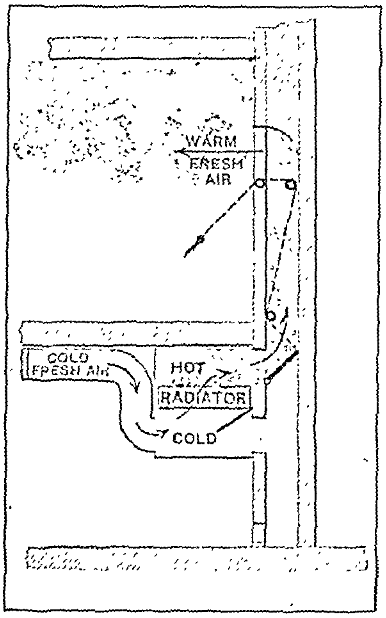

Figure 4.

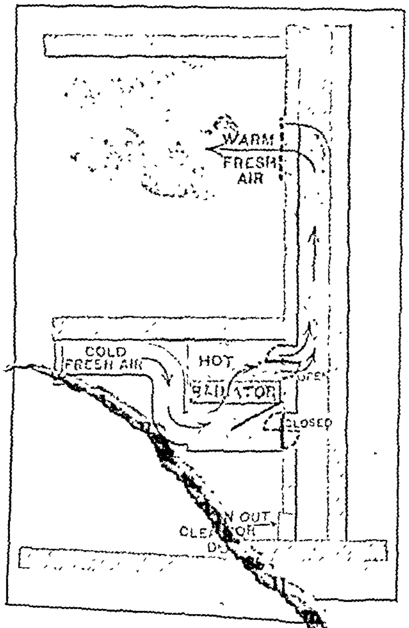

Figure 5.

building (Fig. 2), entering them through the openings in the walls about 8 *feet above the floor*. From thence it is taken, still under pressure (for the doors and windows are all kept shut), into vents or foul-air shafts which conduct the vitiated air from the room at the floor level (Fig. 3). This is the reason why this system *is frequently* known as the "down draught" system—because the *air enters the* rooms at a comparatively [illegible] *level and leaves* at a low level, the draught being, therefore, down.

The varying exposures of the rooms of a school or other building similarly occupied require that more heat shall be supplied to some than to others. With a constant and equal volume of air supply to each room, it is evident that its temperature must be directly proportional to the cooling influences within and around the room, and that no building of this character is properly heated and ventilated where the temperature can not be varied without affecting the air supply. To this end, air of a given temperature may be conducted to the base of each flue and there tempered to a degree suitable to the requirements of the room supplied. The air is heated to the maximum required to maintain the desired temperature in the most exposed rooms, while variety in temperature of air supplied to the other rooms is secured by mixing with the hot air a sufficient volume of cold air at the bases of the respective flues. Here is placed a mixing damper—so designed as to admit either a full volume of hot air, a full volume of cold air or to mix them in any desired proportion without affecting the resulting total volume delivered to the room—the damper should be operated by a thermostat in the room with which the flue connects.

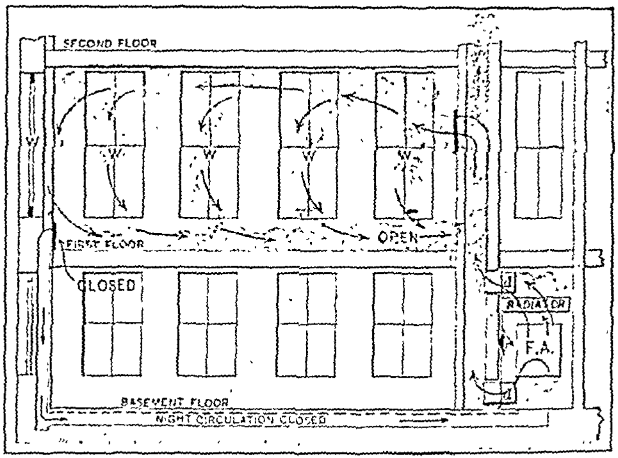

Figure 6.

Being familiar now with the mechanical arrangements of this system, you will readily comprehend the theory of its working. The warm air, as it leaves the register is supposed to rise to the ceiling, expand, and flow out under it, strike the windows on the sides of the room, cool and sink to the floor, and then, under the pressure of the incoming air to return along the floor to the outlet on the same side of the room as the register. In this estimate of the movement of the air, it is held that each child in the school room and each patient in the hospital ward is also a factor in setting up air currents which rise from about the warm body and from the warm lungs to the ceiling, spread to the walls with their contained windows, become cooled at the cool window panes, and sink to the floor to be withdrawn through the vents. One engineer who is evidently a warm advocate of this system says in discussing this point in connection with school rooms: "It may be said that the child is breathing the floor air which is passed to the ceiling over its body, and this is to a great extent true; but it is utterly impracticable to bring fresh air directly to the lungs of each child in a crowded room and therefore all that can be done is to secure a dilution or standard of purity which is reasonably good." (Figs. 7, 8 and 9.) It may be said in conclusion of this part of our subject that those who most favor this system say that the whole matter can not be better expressed than in the words of the late Robert Briggs of the American Society of Civil Engineers in an address on the superiority of forced ventilation:

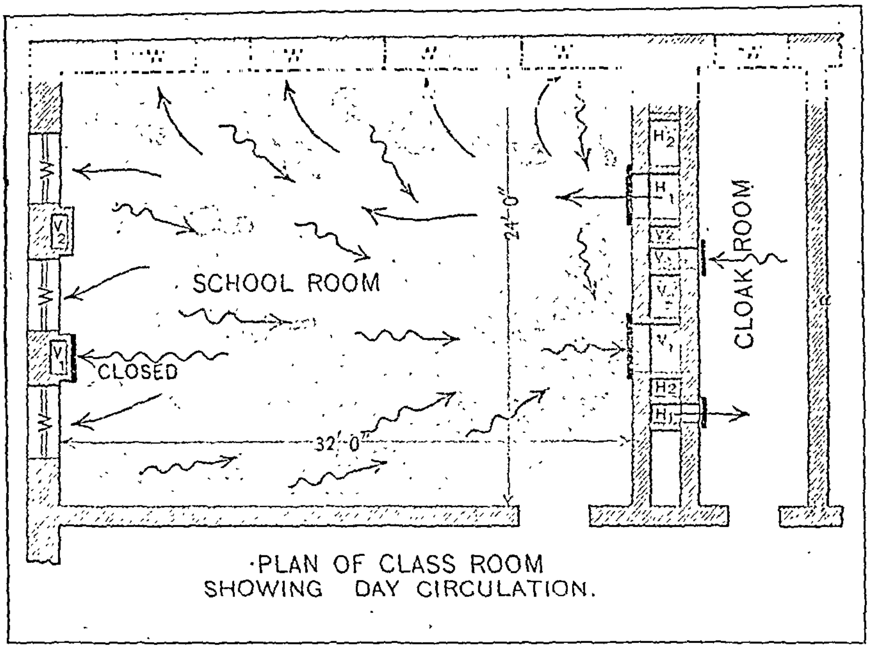

Figure 7.

> This mooted question will be found to have been discussed, argued and combated *on all sides in numerous publications*, but the conclusion of all is that if air is wanted in any particular place, at any particular time, it must be put there, not allowed to go. Other methods will give results at certain times or seasons or under certain conditions. One method will work perfectly with certain differences of internal and external temperatures, while another method succeeds only when other differences exist. One method reaches to relative success whenever a wind can render a cowl efficient. Another method remains perfect as a system, if no malicious person opens a door or window. No other method than that of impelling air by direct means with a fan is equally independent of accidental natural conditions, equally efficient for a desired result or equally controllable to suit the demands of those who are ventilated.

Figure 8.

Having now examined the plenum or down draught system, let us consider some of the theoretical objections to its use and endeavor, if we can, to see how it has worked in practice in the types of building that are the subject of our study.

The most elaborate report that I have been able to find on the subject is that of the Woodbridge Commission on the ventilation of the Capitol at Washington. Among other things they say:

> The relative merit of the upward versus the downward systems of ventilation may be estimated from the following considerations:
>
> 1. The direction of the currents of air from the human body is, under ordinary conditions, upward, owing to the heat of the body. This current is an assistance to upward and an obstacle to downward ventilation.
>
> 2. The heat from all gas flames used for lighting tends to assist upward ventilation, but elaborate arrangements must be made to prevent contamination of the air by the lights if the downward method be adopted.
>
> 3. In large rooms an enormous quantity of air must be introduced in the downward method if the occupants are to breathe pure fresh air, or about three times the amount which is found to give satisfactory results with the upward method. (Figs. 10 and 11.)
>
> 4. In halls arranged with galleries the difficulty of so arranging downward currents that, on the one hand, the air rendered impure in the galleries shall not contaminate that which is descending to supply that main floor below, and on the other hand, the supply for the floor shall not be drawn aside to the galleries, is so great that it is almost an impossibility to effect it.
>
> Perfect ventilation can not be obtained, for this would only provide for the dilution of the impure air, while in perfect ventilation the impurities are not so diluted, but completely removed as fast as formed, so that no man can inspire any air which has shortly before been in his own lungs or in those of his neighbor. For these and other reasons the board thinks that the upward method should be preferred.

The argument that because carbonic acid gas is 52 per cent. heavier than air it is therefore desirable to ventilate by a downward current in a room, rather than an upward one can not be considered a valid one for the very apt reason that Woodbridge gives:

The carbonic acid gas yielded by respiration from the lungs and transpiration through the skin is as thoroughly diffused in the warm air currents rising from the body as is the same gas made by a candle or gas flame in the air currents ascending from those flames. That gas when once diffused in air can, because heavier than air, no more settle downward out of the air and occupy the lower stratum of a room, than the salt, because heavier than water, can settle out of the sea to its bottom. Carbonic acid tests made of the air in two theaters and a music hall in Boston with upward ventilation clearly show air of remarkable pur- transition from that purity to impurity at a ity at the floor or breathing plane and a quick plane at the balcony level, and a further vitiation at the gallery level.

Figure 9.

In case of a crowded theater, samples of air taken near the close of a performance showed the proportion of CO_2 at the floor to average about 4.7 to 10,000; in the balcony, 7.8 to 10,000, and in the gallery, 9.9 to 11 to 10,000; the outside air gave 4.4 to 10,000.

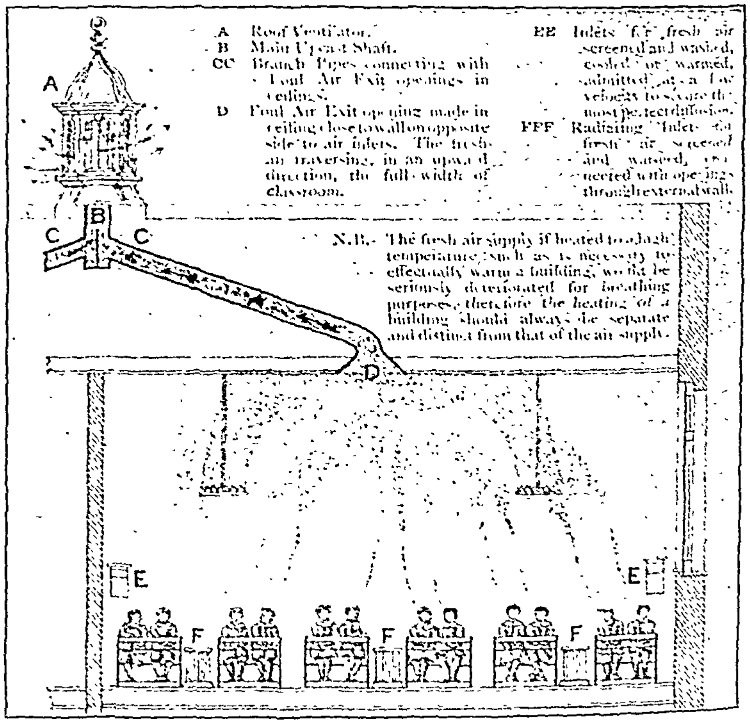
In regard to the mechanical problem involved, the opponents of the "plenum" system urge, and with apparent justice, that the air quantity supplied must be larger for downward ventilation than for upward, because the air brought to the floor by a slowly descending movement of air must inevitably bring back on the breathers the currents of vitiated air which ascend from them. The heat yielded by the body, being nearly that given off by a burning candle, is sufficient to raise 30 cubic feet of air per minute through 10 per cent. temperature. The air in contact with the body or clothing or expelled from the lungs, made moist and warm by the body's heat and vapor, rises in a current which has a far more rapid rate of upward movement than any descending rate which can possibly be given to the mass of air ventilating a hall.

The air breathed by floor occupants *must, therefore,* necessarily be that of the ascending currents of vitiated air reversed by and diluted in the descending mass of *air used in the downward movement.* The inferior quality of air in downward ventilation can be made good only by considerably increasing the air supply, which is done, according to R. H. Smith, by supplying per hour between 30 and 200 times as much air as is actually inhaled by the inmates of the room.

Figures 8 to 12 have been prepared by Robert Boyle, a famous English ventilating engineer, an avowed opponent of the plenum system; that they fairly represent the actual conditions in a hospital or school room can be believed on theoretical grounds. I find in one of the treatises in advocacy of the plenum system the following significant admission:

> The point of discharge should be at least eight feet above the floor and the air movement should be directed toward the outside walls. The ventilation register should be in the same inner wall as the supply opening. but close to the floor. There is thus induced toward this outlet a return flow of the air in a well distributed mass. The currents are in reality stratified, the lower one serving to take up the emanations from the lungs of the occupants as it sweeps slowly across them directly toward the ventilating register. (Fig. 12.)

So much for the theoretical objections to the "forced draught" or "down draught" system. I have observed in my reading on the forced draught system that not only it is sometimes necessary to supplement its heating powers by the addition of a direct radiation system, but one of its advocates, in discussing the fresh air supply, makes the following admission:



A Roof Ventilator.
B Main Upcast Shaft.
CC Branch Pipes connecting with Foul Air Exit openings in ceilings.
D Foul Air Exit opening made in ceiling close to wall on opposite side to air inlets. The fresh air traversing, in an upward direction, the full width of classroom.
EE Inlets for fresh air screened and washed, cooled or warmed, admitted at a low velocity to secure the most perfect diffusion.
FFF Radiating Inlets for fresh air screened and warmed, connected with openings through external wall.
N.B.- The fresh air supply if heated to a high temperature, such as is necessary to effectually warm a building, would be seriously deteriorated for breathing purposes, therefore the heating of a building should always be separate and distinct from that of the air supply.

In hospitals, from a theoretical standpoint, too much air can not be supplied—in practice it frequently runs up to 100 cubic feet per minute and over. In the hospital of moderate size the plenum system will meet all requirements, but under certain circumstances in more complicated structures, it becomes desirable to assist its action by exhaust fans.

Figure 11.

The Houses of Parliament in Berlin were also originally equipped with the down draught system, but the sanitary engineer in charge of the work, being doubtful of the efficiency of the method, planned and provided for an up draught system also. After a practical trial of the down draught system it was considered eminently unsatisfactory for heating and ventilating the parliament chamber, so the up draught system already installed was brought into use, and at present it seems that the down draught system is used for one hour before the assembling of the members at the parliamentary sessions for a preliminary warming of the chamber, and the up draught system is used during the sittings to preserve the freshness of the air and to maintain a satisfactory temperature while the chamber is occupied by members and spectators.

A personal letter from Dr. C. J. McCormick tells me that the down draught system that I have exhibited to you in the Waltham Hospital has been in satisfactory use for thirteen years. Sir Douglas Gallon, F.R.S., in his "Report of the Barracks-and Hospital Improvement Commission," says:

> The writer has visited on several different occasions three of the important hospitals in Europe and the United States of America, in which the ventilation depended on propulsion, and on every occasion the propulsion happened to be out of use for the time.

Taking all things into consideration, it is probable that the most satisfactory and by far the cheapest *method of heating and ventilating hospital wards* and possibly school rooms in this climate, is by direct radiation, the admission of fresh air through short ducts, which on entering the room or wards pass through the radiators, and the allowing of foul air to pass out of the room or ward near the ceiling—in other words, one of the forms of up draught ventilation. Billings says:

> The proper position of the foul air registers depends on the purpose of the room and on the season. *In large assembly* halls and especially where it is desired to provide for respiration, air as pure as possible instead of foul air diluted to a certain standard, the discharge openings should be above. . . . When we come to deal with rooms having a large floor area in proportion to the height and containing fifty or more persons whose heat production is a factor that must be taken into consideration, there is some danger that in the down draught method there will be an unsatisfactory distribution of the fresh air when the temperature of the external air is *not* below 50 degrees F.

If we do not use the down draught system—if we do not use a fan either for the impulsions of fresh air into a building or the extraction of foul air from it there are but two methods left that we can choose from. One is to bring the cold air into the building through a short duct—allow the air to be heated at a radiator and then to allow it to pass off through an up-cast shaft through

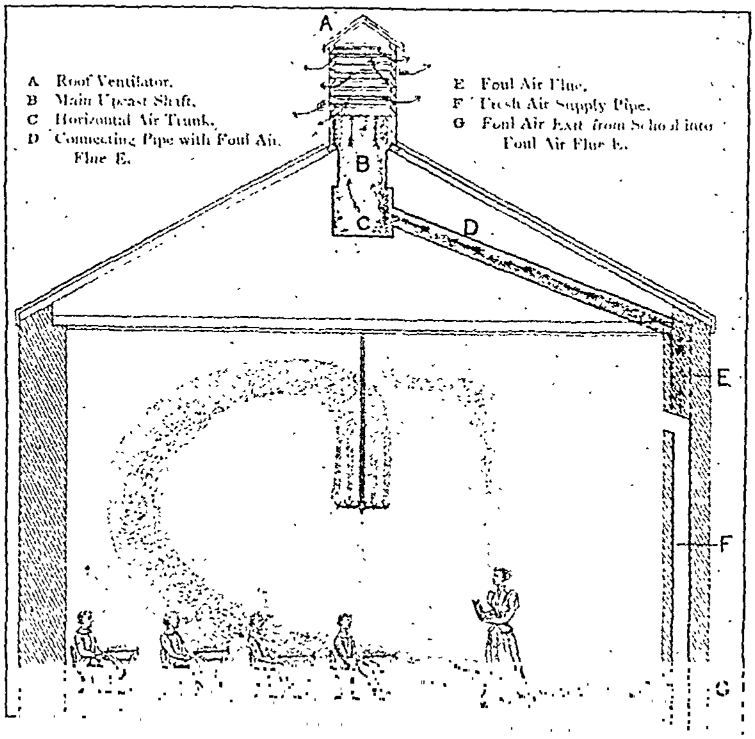

Figure 12.

The carbonic acid gas yielded by respiration from the lungs and transpiration through the skin is as thoroughly diffused in the warm air currents rising from the body as is the same gas made by a candle or gas flame in the air currents ascending from those flames. The Houses of Parliament in Berlin were also originally equipped with the down draught system, but the sanitary engineer in charge of the work, being doubtful of the efficiency of the method, planned and provided for an up draught system also. After a practical trial of the down draught system it was considered eminently unsatisfactory for heating and ventilating the parliament chamber, so the up draught system already installed was brought into use, and at present it seems that the down draught system is used for one hour before the assembling of the members at the parliamentary sessions for a preliminary warming of the chamber, and the up draught system is used during the sittings to preserve the freshness of the air and to maintain a satisfactory temperature while the chamber is occupied by members and spectators.

A personal letter from Dr. C. J. McCormick tells me that the down draught system that I have exhibited to you in the Waltham Hospital has been in satisfactory use for thirteen years. Sir Douglas Gallon, F.R.S., in his "Report of the Barracks and Hospital Improvement Commission," says:

> The writer has visited on several different occasions three of the important hospitals in Europe and the United States of America, in which the ventilation depended on propulsion, and on every occasion the propulsion happened to be out of use for the time.

Taking all things into consideration, it is probable that the most satisfactory and by far the cheapest method of heating and ventilating hospital wards and possibly school rooms in this climate, is by direct radiation, the admission of fresh air through short ducts, which on entering the room or wards pass through the radiators, and the allowing of foul air to pass out of the room or ward near the ceiling—in other words, one of the forms of up draught ventilation. Billings says:

> The proper position of the foul air registers depends on the purpose of the room and on the season. In large assembly halls and especially where it is desired to provide for respiration, air as pure as possible instead of foul air diluted to a certain standard, the discharge openings should be above. . . . When we come to deal with rooms having a large floor area in proportion to the height and containing fifty or more persons whose heat production is a factor that must be taken into consideration, there is some danger that in the down draught method there will be an unsatisfactory distribution of the fresh air when the temperature of the external air is not below 50 degrees F.

If we do not use the down draught system—if we do not use a fan either for the impulsions of fresh air into a building or the extraction of foul air from it there are but two methods left that we can choose from. One is to bring the cold air into the building through a short duct—allow the air to be heated at a radiator and then to allow it to pass off through an up-cast shaft through

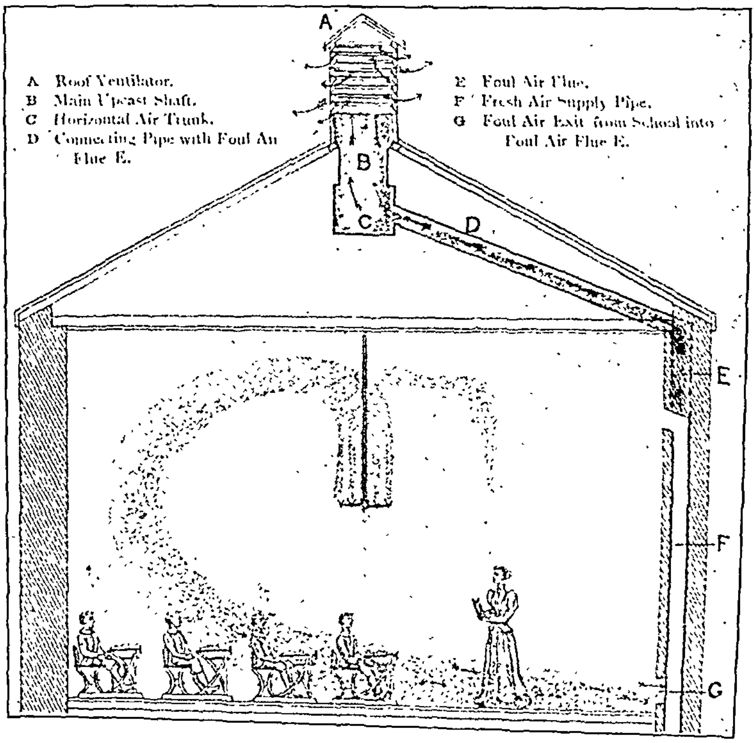

Figure 12.

or near the ceiling. It is held that it is frequently necessary to aid the extraction of the vitiated air by placing small radiators in the extracting shafts so that the air in these shafts shall be heated and thereby acquire an upward movement. It is pointed out that this is a waste of heat, for the radiated heat subserves no other purpose than that of warming the air in the shaft and is an expensive motive power. This may be admitted, but is probably balanced by the necessary overheating of the very much larger quantities of air required to be delivered by the plenum system. In many structures these vents can be run to the smoke stack from the fire boxes of the boilers and will there be heated sufficiently to maintain a good up draught. One of the most reasonable methods that I am acquainted with is that of an English engineer who has planned what he calls a natural method of ventilation, although this term is usually applied to ventilation by means of doors and windows, which the sanitarians consider as no ventilation at all. In this Boyle system the heating and ventilating systems are independent. Radiant heat is used. Boyle's summary description of and rehearsal of the advantages of his system is as follows:

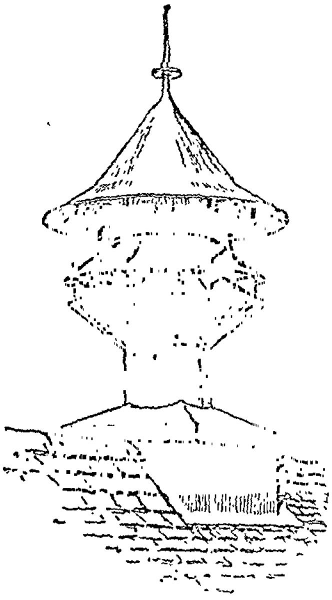

Figure 13.

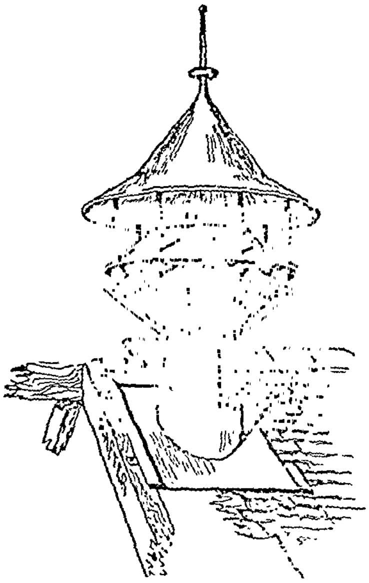

Figure 14.

> Natural ventilation properly applied is the most constant and reliable. It requires little or no attention, is always in action and can not get out of order or break down, as so often happens in mechanical ventilation. Care should be taken in the employment of ventilators that they are of correct construction and that both the outlet and inlets are sufficient in size and number and so placed as effectively to accomplish the work they have to do.
>
> The outlet ventilators should be fixed on the highest part of the roof, clear of all obstructions, so that the wind can reach them freely from every quarter. (Figs. 13 and 14.) The fresh air supply should be properly proportioned to the extraction. The combined area of the inlets should in all ordinary cases be at least equal to that of the outlet shaft. Main exhaust shafts should be at least of equal area to the combined area of the branch pipes. Branch pipes should have as great an upward angle as possible and should never enter the main shaft at the same level unless when parallel. All pipes should be made of metal and circular in shape to reduce friction. The vitiated air should be extracted at the ceiling, to where it naturally ascends. The fresh air should be admitted directly through the walls at a low velocity in an upward direction through a number of small inlet brackets or tubes distributed around the walls to secure more complete diffusion and an equable movement of the air in all parts of the building. (Figs. 15 and 16.) Air never should be admitted in cold weather in a horizontal direction, as a dis-

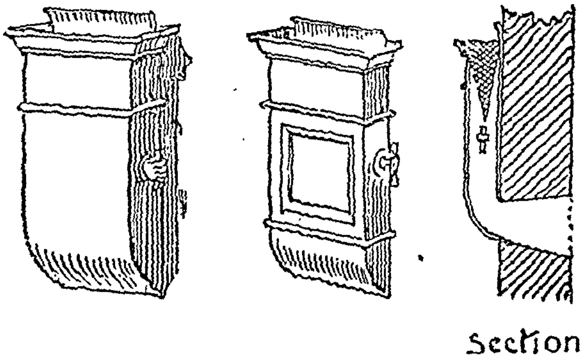

Figure 15.

Figure 16.

agreeable draught would result. The velocity of the air supply should not exceed two feet per second. The inlet channels should communicate directly with the outer air, be as short as possible and easy of access for the purpose of cleaning. Long inlet channels are objectionable, as they harbor dirt and are difficult of access. Where simple tubes or brackets are used the tops should be about 5 feet 9 inches above the floor. Where the air supply is warmed it may be delivered at a lower level (that is where it passes through radiators in entering the room). The inlets should be fitted with regulating valves to control the air supply. The fresh air supply should not be overheated, as its hygienic properties are thereby seriously impaired. Heating a building by hot air should, therefore, be avoided, as injurious to health. Radiant heat is the healthiest and most effective. Where open fires are used, they should have a separate air supply, led directly to them from the outside air through a 3 or 4 inch pipe to prevent them drawing the hot vitiated air from above down into the breathing air, creating draughts and unduly affecting the ventilating arrangements. Figures 17 and 18 well illustrate the principle of this system.

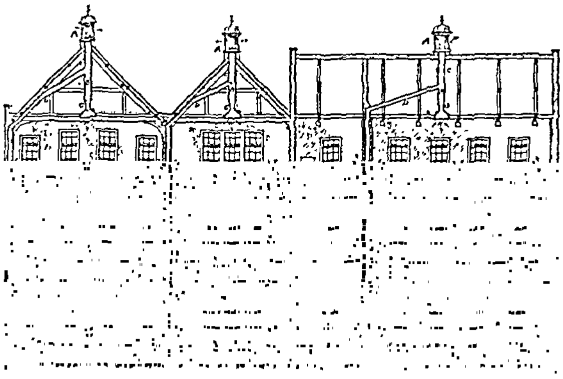

Figure 17.

Sanitarians and intelligent educators everywhere are clamoring for the proper and systematic medical inspection of school children and it behooves us whose province is the eye heartily to second their efforts and to urge on the tardy school authorities the paramount importance of this work not only in the preservation of the general health of the scholars but also in the interest of their eyes.

I need not remind you of the value of the work of Cohn of Breslau, Williams and Ayres of Cincinnati, Agnew of New York, Derby of Boston and Risley and his associates of Philadelphia, in working up the subject of the production of myopia in school children by the ill-lighting of school rooms and the congenital anomalies of refraction in children whose vision has not been corrected on account of the neglect or ignorance of parents or teachers. We have already gathered together sufficient facts on this subject to justify a vigorous demand for the expert examination of the eyes of all school children as soon as they reach an age when they can be intelligently examined. We must not lose sight of the fact, however, that momentous as the subject of progressive myopia is, there are other conditions of the eyes that just as earnestly demand our attention. In a recent most excellent address on school sanitation, Dr. F. G. Byles of Denver tells us:

> In ten months' inspection of Philadelphia schools 3,446 cases of infectious diseases were found. During the first five months of school inspection in Newark, N. J., in less than 6,000 pupils, more than 1,700 cases of infection were found. In Chicago, in four months, 1,417 cases of diphtheria and 306 cases of scarlet fever were found in the school rooms. . . . The inspectors in Chicago schools in five months of 1900 found 670 children with chickenpox, 55 with whooping cough and 648 with measles attending school.

To the members of this Section the infectious diseases, such as diphtheria, scarlet fever, measles and whooping cough, have each their own ocular significance in paralyzed muscles, conjunctivitis, keratitis, iritis and inflammations, and the serious results that we have seen follow the course of the acute infections should be communicated to the authorities as an additional argument of the greatest weight for the prompt establishment of medical inspection in all schools where it is not now in force. Any poison is virulent or harmless in proportion to its concentration or dilution. The air of school houses is necessarily vitiated by the exhalations from the lungs and bodies of the children. Add to it, in addition, the germs of infectious diseases, as we have just seen is so often done, and we can appreciate how vitally important it is that the ventilation of school houses should be as perfect as possible.

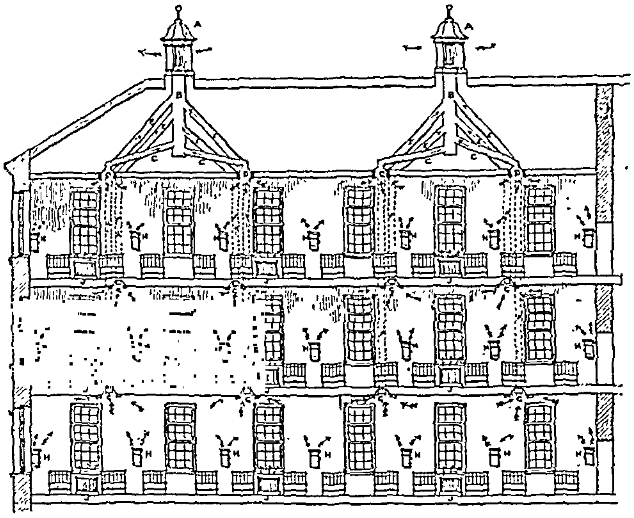

Figure 18.

The relation of the proper lighting and ventilation of school houses to the health of our children is so intimate, and we already know so well what should be and what should not be, that it is our duty to the commonwealth to insist that expert advice should always govern in the erection of a school building, and we must not cease in our demand for what is right until we have a competent medical inspector at every school house at the assembly hour to send the ailing children to their homes and to protect the healthy children in the school house.

In conclusion, I will read a very much condensed summary of the methods of heating and ventilating found in various Eastern hospitals and public buildings and noted by the architect of our new Cincinnati General Hospital during a recent trip that our commission took to Washington, Baltimore, Philadelphia, New York, Boston, Buffalo and Cleveland:

WASHINGTON.

Congressional Library.—Hot-water heating. Partly direct and partly indirect. Independent hot-water heaters under each wing. Small fans used in summer only to force fresh air into the various reading rooms. No fans used in heating. Ventilation by aspirating shafts.

Garfield Hospital.—Old building, direct steam; new building, indirect steam. No fan.

BALTIMORE.

Johns Hopkins Hospital.—Hot-water heating; gravity system. Indirect in wards; direct in corridors and offices. Ventilation by aspirating shafts.

PHILADELPHIA.

Medico-Chirurgical Hospital.—Hospital wards and clinical amphitheater heated by motor-driven fan through indirect steam coils. Offices, corridors, etc., direct steam.

Hahnemann Hospital.—Direct steam heat; indirect in new amphitheater. No fan.

Pennsylvania Hospital.—Central building heated by hot-blast fan system; wards, indirect steam without fan; corridors, etc., direct steam.

University of Pennsylvania.—Laboratories (new), corridors, offices, etc., direct steam. Laboratories, operating room, etc., have hot-blast fans and eduction fans; latter not in use. Medical department, direct steam.

New Municipal Hospital for Contagious Diseases.—Indirect steam from central plant. No fans.

NEW YORK.

Presbyterian Hospital.—Heated with indirect steam coils operated by fan. The superintendent, Dr. Fisher, does not approve of system.

Mt. Sinai Hospital.—Equipped with hot-blast system and eduction fans on roof. Also direct steam heaters under all windows in wards and corridors. Fan system not used. When visited by committee ventilation was effected by opening the windows.

Lying-in Hospital.—Fan system—one set to blow in and one set to draw out. Also some direct radiation in each room. Blowing fans not used. Eduction fans only in use. This saves $3,000 per year.

New York Hospital.—Fan system, blowing tempered air through indirect coils. In use all the time.

St. Luke's Hospital.—Heating, direct steam. Exhaust fans used for ventilation; in use part of the time.

BOSTON.

Massachusetts General Hospital.—Old buildings, indirect steam; no fans. New buildings, double fan system, one to blow in and one to draw out; both in use.

Boston City Hospital.—A mixed system; partly direct steam and partly indirect steam, with aspirating coils. Surgical building, fan system.

BUFFALO.

General Hospital.—Hot-blast fan system; objected to; hard to work. No thermostatic control. No exhaust fans. Ventilating flues through roof.

CLEVELAND.

Lakeside Hospital.—Fan system through individual stacks. Bottom heat inlets (a mistake). Bottom vents carried down through basement to hot stack.

FIBROID GROWTHS OF THE ABDOMINAL WALL.*

CHARLES A. POWERS, A.M., M.D.
Professor of Surgery in the University of Denver.
DENVER.

The comparative rarity of these so-called desmoid tumors may be seen by referring to very recent statistics gathered by Cabot[1] of Boston, who found but 3 of this nature in a series of 4,876 abdominal tumors encountered at the Massachusetts General Hospital. Ledderhose in 1890 was at some pains to collect 100 cases. More recently, Pfeiffer[2] cites 40 cases seen in the Tübingen clinic during the past 46 years, and adds to this 360 other cases which he gathered from literature.

The term desmoid, by which these growths have generally been described, originated with Johannes Müller in 1838, and was intended to designate tumors of the musculo-aponeurotic tissues of the abdominal wall (tendon-like neoplasms). My own attention was directed to these rather curious growths by three cases seen, respectively, at the New York Cancer Hospital, St. Luke's Hospital in New York and at the City and County Hospital in Denver. These cases were practically duplicates. Each occurred in a young woman between 25 and 35 years of age who had recently gone through pregnancy. In each the growth was in the region of the right rectus muscle and near the level of the umbilicus. In two the peritoneum was involved and required excision; in the other the peritoneal cavity was not opened. In one the size of the growth is described in my notes as "about the size of a pullet's egg;" in one it was the size of a small orange; in the other, that of a little baby's fist. In each of the three cases the hospital pathologist reported the growth to be a fibroid. Each patient made a prompt operative recovery. In two cases the fate of the patient after leaving the hospital is unknown to me. In the third, a patient operated on in the City and County Hospital in Denver in June, 1904, there has been no relapse as yet.

I have made but brief mention of my own cases, but on examining the literature of the subject I am struck by the fact that most of these growths occur in practically the same way.[3]

Pfeiffer analyzed 400 cases, and his observations are so valuable that I shall quote from them at length and without apology.

No cases are included in the category except those which really began in the muscles and aponeuroses. This excludes tumors beginning in the round ligaments, in the periosteum of the ribs, pelvic bones and vertebræ, and in the ligamentum teres, all of which may present themselves as tumors of the abdominal wall despite their peduncular attachment to the outlying tissues.

Desmoids, unlike sarcomata in the same situation, occur in the great majority of cases in women—the ratio being about 7 to 1.

In regard to the influence of previous pregnancy, Pfeiffer has data in 265 cases, and of this number 250 women, 94.3 per cent., had borne children—usually more than one. The tumor appeared, as a rule, immediately after delivery, and in only 15 is it expressly stated that the woman was pregnant when the growth appeared. Naturally, a majority of women were of child-bearing age; 146 were between 25 and 35, 41 were between 15 and 25, and 35 between 35 and 50. Only 15 women were over 50. In a considerable number the age was not given. A very few women were over 60. Of the few men observed, the common age was between 35 and 50. There are also a few cases recorded in children; some of these were undoubtedly congenital.

Heredity may be disregarded as a causal factor. and the very great majority of the growths were single.

Location.—In 185, or 72.5 per cent. of available cases, the growths were below the navel; of these 37.2 per cent. were to the right side, 27 per cent. to the left, and 8.2 per cent. in the middle line (absolute ratio, 51 per cent., 37 per cent. and 12 per cent.).

In that part of the abdominal wall above the umbilicus desmoids occurred much less frequently, in all 41, or 16.1 per cent; 17 on right side, 20 on the left side and 4 in the middle line (ratio, 41 per cent., 49 per cent. and 10 per cent.).

Of the total number 26, or 10.2 per cent., were neither above nor below the navel, but on a level with it—10 to the left and 16 to the right.

Finally, there were 3 in the region of the loins—2 on the right, 1 on the left.

Summary		R.	L.	M.
Above navel	41	17	20	4
Even with navel	26	10	16	0
Below navel	185	95	69	21
Lumbar	3	2	1	0
	255	124	106	25

The point of origin may be a more or less broad pedicle attached to fascia or muscle. Of 268 cases in 115, 43 per cent., the origin was from the rectus muscle. In 13 cases from the anterior and in 34 from the posterior lamina of the fascia, while in the remaining 68 the point of origin is not stated. In 47 cases, 17.5 per cent, the oblique muscles were the origin, in the following order of frequence: Internal oblique, external oblique and transversalis. In 45 cases, 17 per cent., the origin was the abdominal fascia; 10 times from the superficial and 35 times from the deep. In 29 cases the tumor arose from two muscles, and in 29 others so many muscles were involved that the origin could not be determined.

The fact that most of the desmoids arise from the rectus corresponds to their lateral location, and to other points in their localization, such as predominance in the right pubic region.

In form the tumor is usually roundish or rather ovoid. As a rule the long axis of the mass corresponds to that of the course of the muscles and tendons from which it arises. The direction of the growth is usually determined by the resistance encountered. Hence, in primiparæ and in nulliparæ the firmness of the abdominal wall anteriorly prevails over that in the rear. In such cases—relatively few—the tumor grows inward, and has a spheroidal or mushroom shape. When the walls have become lax from child-bearing, however, the tumor grows toward the surface, even when it arises from the posterior sheath of the rectus; showing that the resistance from behind (transversalis fascia, peritoneum and intestines) exceeds that of the abdominal wall in front. The least resistance encountered is in the muscles themselves in their long direction, this favoring the flattened or ovoid shape. When a tendon or muscle sheath is encountered a constriction results and the tumor grows above and below it, producing the so-called cuff-button form. Multiple constriction produces lobular forms, which may simulate multiple tumors.

While the attachment is usually broad, so that the mass lies in its bed like a disc, slender pedicles may occur. Frequently extirpation may be accomplished by shelling the tumor out of its bed. A capsule is usually present, but this becomes atrophic from pressure. It is not involved in the growth of the tumor in the majority of cases, but often when the growth exhibits sarcomatous tendencies a diffuse union of the tumor with the surrounding tissues is found, and extirpation can be effected only by the knife and scissors.

In many cases (especially in those reported from French sources), a connection is mentioned as existing between the desmoid and some osseous structure (false ribs, ilium, pubic bone). This is termed the bone pedicle. Although their existence has been denied, there is good evidence that such secondary bone pedicles sometimes do occur. Olshausen, who has seen such cases, believes that these pedicles may be primary. Such a view would confound desmoids with true tumors which originate from periosteum. In Pfeiffer's 400 cases, no less than 65 (16.25 per cent.) had osseous attachments, 35 with ilium, 8 with pubic bone, 6 with false ribs and 1 with spine. In two cases there was attachment to two bones—ilium and os pubis.

The rate of growth and size of the tumor vary extremely; in many cases several years, even several decades, may show hardly any change; then a sudden and rapid growth may set in. In other cases, the growth may be rapid at first, but when a certain limit has been reached (size of head) the growth may remain stationary for years. Rapid growth does not necessarily mean malignancy. Sometimes tumors are seen which prove fatal when their growth has been slow throughout. One patient who refused operation died in 18 months.

The usual size of a desmoid is from that of a hen's egg to that of a large fist. It is not rare to see them as large as a child's or adult's head. They may attain a weight of 2 or 3 kilos. Very exceptionally great weights have been recorded—up to 10 kilos. Some of the oldest reported cases had weights of 17 kilos, 22 kilos, etc. This may be explained by the fact that these tumors cause relatively little trouble, and hence may have been allowed to grow indefinitely before medical advice was sought.

It has very often been noted that the desmoids were first noted during pregnancy (including puerperium) or else began to grow rapidly at that time, to become stationary again after the childbirth was over. This happened in 99 out of 400 cases (about 25 per cent.) Growths extirpated during pregnancy may recur during a subsequent gestation.

In nulliparæ and in males, trauma is frequently accused as a cause (about 7 per cent. of the entire number).

Pathologically these desmoids are firm, hard masses, usually enveloped in a membrane. They creak when cut, the section being pale-red or whitish-yellow and tendon-like. The presence of escaped and altered blood may color the tumor a brownish hue. The texture, in general, is uniformly hard and firm—bundles of fibers may be seen in a network or sometimes in concentric grouping, dividing the area into nodes. The desmoid is poor in vessels, and hence areas of softening may occur. The edema which precedes it may be of such degree as to simulate fluctuation. These areas of softening often lead to the formation of cysts, and these are sometimes hemorrhagic.

Microscopy shows the bundles of fibers already mentioned closely adherent to the adventitia of the vessels. Where edema occurs, the bundles are pushed apart. More or less proliferating tissue is present—as shown by young connective-tissue corpuscles in the course of transformation into fibrillæ. When this immature tissue is especially abundant and collected into clusters the tissue of a sarcoma, round or spindle cell, may be simulated. This may lead to mistaken diagnosis when a piece of tumor is excised before operation. Some cases thus diagnosed as sarcoma have not relapsed even when extirpation was incomplete; other cases diagnosticated as desmoid have rapidly recurred (the latter mistake is much more infrequent). A microscopic diagnosis in advance of operation can not be made with certainty and does not give any guide to prognosis as to recurrence. The amount of formative tissue present is likewise no criterion of benignancy or malignancy.

The "more or less cellular fibroma" is the most common type of the desmoid, especially in women. Pure sarcoma (round or spindle cell, and oftener the latter) also occurs, especially in men. Other types of sarcoma are rare or absent, save cysto-sarcoma. (It seems to me that all sarcomata should be excluded from this class.) As far as the material is available, 88.2 per cent. of all cases in women were cellular fibromata and 11.8 per cent. sarcomata; in men the two percentages were 75.6 and 24.4.

In only 14 cases, 4.67 per cent., was there a mixture of myxomatous tissue. There was a single case of pure myxoma and no instance of myxosarcoma. Calcification occurred in 4 cases. A doubtful case of suppuration of a desmoid is recorded.

Several authors record the presence of smooth muscle (fibromyoma). Of a number of alleged cases Pfeiffer selects some 5 as genuine. Others may be added, but description is not sufficiently thorough. All cases, real or alleged, are in women, but by no means confined to the round ligament region.

Under etiology some points have already been mentioned. Grätzer has elaborated an embryonal theory (confusion of mesodermic elements, both peritoneum and fibrotendinous portions of the abdominal wall being derived from that layer). Herzog has formulated a traumatic theory, based on the possibility of injury to the rectus muscle, formation of organized hematoma (muscle callus) and eventual tumor formation. This view has been well supported in literature, but can not be made to apply to other muscles when injured.

Sänger has apparently refuted both the preceding theories. Simple homologous tumors do not have an embryonal origin, while desmoids show no evidence of hematomatous origin.

Guinard and other French authors seek to connect all desmoids with the round ligament, as far as women are concerned. Cases in men are placed with sarcomata. This view is opposed by facts already cited.

As far as trauma to muscle is connected with pregnancy, etc., obstetricians are almost universally silent as to such injuries, hematomata, etc. The exception is Stoeckel, who has reported 2 cases of hematoma of the abdominal wall in pregnancy. Not only could he find no other cases in literature, but both his own occurred under peculiar circumstances, viz., severe paroxysms of coughing and with a general hemorrhagic diathesis.

Numerous cases of hematoma of the abdominal wall from trauma have been recorded in man, but none was ever known to cause a desmoid, unless we include certain cases of keloid, which present some resemblance. If desmoids arise from trauma they should be much more common in men. Certain lesions—indurations, hematomata, cysts, keloid—have been known to follow injury to the muscular region, but they follow closely on the latter. Desmoids, on the other hand, differ greatly from such sequelæ.

Ribbert's theory of tumors may be applied to desmoids. This is a modification or expansion of the old Cohnheim theory as applied by Grätzer. As applied by Lücke, it depends on the plasticity and distention of the abdominal wall as a result of pressure of the gravid uterus, thus favoring the proliferation of connective tissue elements by reason of diminished resistance—the best answer to this view is that we do not see desmoids follow distention from ovarian tumors and the like, while the sexual organs proper undergo a degree of softening which might favor proliferation of elements previously held in check. This feature of pregnancy can not be applied to the abdominal walls.

Wischnewsky has recently made exhaustive studies of the distended abdominal wall. He states that in pathologic conditions the muscles atrophy, while in pregnancy they undergo hypertrophy in which the fibrous tissues participate. Durante has made the same observation.

This fact enables us to exclude distention as an efficient cause. The connection of desmoids with pregnancy can not be explained in this way. With a normal hypertrophy of the fibrous structures occurring at this period, the presence of young connective tissue at once suggests a possible factor in the causation of these tumors. The coincident distention and stretching of the abdominal wall could then be invoked as a secondary factor. To produce a truly pathologic state it would still be necessary to call on the misplaced germinal matter dating from the embryonal period.

These three factors, viz., diverted or superfluous embryonal elements, a state of active proliferation of normal fibrous tissue and a stretching or loosening of the parts involved, only apply to pregnancy. In trauma there is not the stretching, but there is an edematous succulence which may produce an analogous result. Individual cases of desmoid following laparotomy scars, the pressure of a belt buckle for a long period, etc., could also be thus explained. A single blow, laceration, etc., may be and often have been alleged as causes. But the formation of a hematoma is not a necessary step.

In regard to symptoms, subjective disturbances are usually absent at first, and women seek operation for cosmetic reasons only.

When the growth reaches the size of an English walnut, pain may appear in various types, local or radiating, worse during the menses or present only at that time. In very nervous women, the presence of the pain may cause great discomfort; rarely convulsions or hallucinations, which disappear with extirpation. When the tumor grows rapidly, attaining a considerable size, patients complain of peculiar painful sensations, due perhaps to compression of nerves or to stretching of skin. Medical aid may now be sought and an erroneous diagnosis of malignancy may be made. Pressure symptoms are usually absent, as is also distress from external contact. Tenderness to pressure is usually absent as well. The skin may or may not be stretched and glossy; with large tumors *striæ atrophicæ* appear. Adhesion with the skin if of rare occurrence; when present it causes redness and edema and even ulceration, phlegmon and sepsis. The most cellular type of fibroma, with relapse of same, almost never involves the lymphatics.

Diagnosis is by no means so easy as might appear. When small and not adherent beneath, diagnosis is easy; no so when opposite conditions exist. Characteristic is the readily mapped out limits, the conformity in direction with the muscles, the degree of mobility—these may be made without narcosis. These desmoids of the rectus are naturally movable from side to side chiefly. Bouchacourt's symptom is of value—the patient sets her abdominal muscles in voluntary contraction by rising from a chair without aid of the arms; during this contraction all mobility of the tumor disappears. If the tumor then becomes more prominent, it is probably derived from the superficial muscular layers; if it becomes less prominent, its origin is from the deeper layers. This maneuver may not succeed if the abdominal wall is either unduly firm or unduly lax. As compared with abdominal tumors of deeper seat, the parietal kind do not change their position with change of posture. Bulging outward is very characteristic of desmoids, this being much more marked than mere palpation would seem to indicate. Unless deep adhesions have formed there is no change of position during respiration.

Diagnosis, however, is often not only difficult, but apparently impossible. A large number of mistakes are on record in which desmoids have been confounded with other conditions—various cysts, tumors of the gall bladder, omental tumors, salpingitis, appendicitis and other intra-abdominal affections. Hence the necessity of differential diagnosis between desmoids and a host of other intra-abdominal conditions. Exploratory incision and exploratory laparotomy may be necessary. Narcosis will exclude hysterical tumors. Vaginal and rectal exploration may be of aid.

Treatment is purely surgical, and the desmoid should be extirpated at once. The surgeon must beware of too radical intervention, as the operation may leave a breach in the abdominal wall which can not be repaired. In pregnancy, extirpation is indicated in the early months, but in the later months operation must be deferred until after delivery; otherwise the operation scar would be likely to rupture. Some authors, however, do not advise waiting.

As even the smallest desmoids, when they arise from the posterior aspect of the rectus, may necessitate a peritoneal resection, such a contingency must be prepared for.

In operating, the incision must be in the direction of the long axis of the tumor. The skin and muscular layers are first divided. If the tumor is encapsulated, not adherent and sharply outlined, it may be removed by blunt dissection. If at any point it appears to have involved the investing tissues, free excision must be made. It is of no use to attempt a blunt separation of the peritoneum, and one should not hesitate to open the abdominal cavity. General narcosis must be employed. Successful cases of imperfect removal must not be allowed to influence the surgeon, for these are rare exceptions. Even when the desmoid can be removed extraperitoneally, it is sometimes wise to resect the peritoneum in order to prevent infection by facilitating drainage. Cases of peritonitis have been reported in which that membrane was not involved in the operation. Under such circumstances two cases have terminated fatally.

Resection of the peritoneum and extirpation of the tumor adherent thereto is, in general, best done as follows: At the edge of the tumor a small incision is made through the membrane and the tumor is excised. Sänger, who lost a case by hemorrhage into the peritoneum, proposed the use of "arcade ligatures" about the tumor which was to be excised.

If such large areas of peritoneum must be removed that the breach can not be closed by primary union, the wound must be made as small as possible by suture, after which the edges are to be stitched to the omentum.

Postoperative hernia is best prevented by separate suture of each plane. If necessary, the opposite muscles may be used for plastic purposes.

If the entire half of the abdominal wall is involved, the skin should be spared in the excision of the tumor; it may be of value in closing the breach if muscle plastic is available. If the flaps left in certain cases are redundant, König's plan may be followed; that is, the skin may be arranged in cock's-comb fashion and the subcutaneous tissues sutured together.

If suture in individual planes has been effected, there is no need of a retentive band. Under other circumstances a bandage must be worn for several weeks after complete healing of the wound.

The immediate results of operations on desmoids of the abdominal wall have been relatively favorable since the introduction of asepsis. Discarding some of the older material Pfeiffer has notes of 285 patients operated on. Of this number the abdominal cavity was opened in 119, 40.8 per cent. The primary mortality in these cases was 10 cases, 3.5 per cent. In 142 cases, 49.8 per cent., extirpation was effected without opening the peritoneum. The mortality here was 3 cases, 1.05 per cent. In 24 cases details as to peritoneum fail. The combined mortality was 4.55 per cent. Of the 13 cases, 7 patients died of collapse or secondary hemorrhage and 6 of peritonitis.

In regard to ultimate results Pfeiffer avails himself of 107 cases, 85 females and 22 males. Relapse occurred in 33, 30.8 per cent.—15 males, 18 females. In 17 cases, relapse was fatal—11 males, 6 females. Hence, relapse occurred in males in 68.1 per cent. and was fatal in 50 per cent. Relapse occurred in females in 21.2 per cent., mortality but 7 per cent.

Late relapse occurred at varying intervals. In no case did it occur in the first 3 years among the women (40 cases studied), but 2 men had relapsed (out of 5 studied) within that period. In the cases of late recurrence studied in women, 3 in all, the interval after operation was 4, 7 and 9 years, respectively. In the 2 cases of early relapse in men, there was a history of repeated relapse; in one the interval was brief, in the other 14 years.

It is but natural to assume that the smaller the growth at the time of extirpation the less will be the liability to recurrence.

DISCUSSION.

Dr. Robert F. Weir, New York, said that this is a rather rare affection, but he has met with it twice and both cases were in young unmarried women between the ages of 30 and 35. The first tumor he thought was an ovarian tumor with very solid contents. He made an incision which revealed the fact that it was not in the abdominal cavity. The adjacent tissues peeled off readily and the mass weighed fourteen pounds. The attachment was along the line of the right linear semilunaris. The patient recovered with a fair condition of the abdominal wall and remained well for several years when she passed from his observation. The younger patient had a little different tumor in the lower right side. It was removed by incision; the attachment was in a similar situation, but it demanded some sacrifice of muscular tissue. Under the microscope it was pronounced to be purely fibrous, but it recurred eight months afterward, when after removal it was pronounced to be a spindle-celled sarcoma. If it had been carefully examined all over by the pathologist it would probably have shown in some parts of the eight pounds that it was a spindle-cell sarcoma. It recurred again, and was again removed when it had recurred, but he refused to do anything further surgically. She was treated by erysipelas toxins by an expert, under which treatment she improved to some extent, but eventually she returned to the hospital and died from the tumor. This case shows that these large masses are at times malignant. In the second procedure help was derived by liberating the peritoneum from the adjacent extraperitoneal tissues. In this way adhesions were avoided.

Dr. Emmet Rixford, San Francisco, mentioned a similar case occurring in a young woman of 27 who had been pregnant some time before the tumor was discovered. The tumor grew slowly but continuously and when operated on it measured 4x8 inches. It was somewhat the shape of a modern football, was smooth in outline and situated in the anterior abdominal wall at the outer edge of the left rectus muscle. The operation was simple. The growth, which was situated in the internal oblique muscle, was simply shelled out. The peritoneum was not opened. The muscles were drawn together with chromicized cat-gut and wound closed. Although the operation was done some ten years ago and the patient has since been through two childbirths there has been no recurrence of the tumor and no hernia. The tumor was diagnosticated as sarcoma but it was definitely a desmoid, although the pathologist was unable positively to exclude malignancy because some of the areas in the tumor were evidently sarcomatous while other areas were apparently of simple fibrous tissue.

Dr. Alexius A. McGlannon, Baltimore, stated that recently he had a similar tumor for three years. After operation the patient was free from the growth for fifteen months and then it recurred and was again removed. The first tumor was a soft fibroma, while the second showed all the varieties of malignant connective tissue tumors. It was lobulated, some lobules showing fibro-spindle-cells sarcoma, and some mixed spindle and round cells. The second operation was only done in May, so that Dr. McGlannon does not know the results. The fact that the tumor became more prominent after contraction of the abdominal muscles was considered important, indicating a superficial position; but the tumor involved the entire thickness of the wall from subcutaneous fascia to peritoneum, and became prominent when the muscles were contracted because of intra-abdominal pressure.

Dr. J. P. Connell, Fond du Lac, Wisconsin, reported two cases, one of which was a tumor of the rectus muscle, the size of an egg, which has not recurred. The second case occurred six months ago, and the tumor extended from the erector spinæ almost around to the ribs. He took a section of the growth and the pathologist reported a fibroma; he then advised removal. He dissected the growth out from the rectus muscle, a great deal of which was involved, as were several other abdominal muscles. The attachment extended to the periosteum of the ribs and in operation he removed a section of several of them. The patient made a good recovery. In his dissection he made a large flap and after turning out the growth stitched the flap back into place.

Dr. O. O. Witherbee, Los Angeles, reported a case involving the left rectus muscle following an operation for salpingitis. The microscope gave a spindle-cell appearance but not exactly of the sarcomatous type. To have removed it would have left the patient without any abdominal wall, and he therefore advised using the Coley fluid. The patient had been reduced in weight to 85 pounds when beginning the serum, so that the prognosis was most unfavorable. He used the serum under protest, but it looked like a last resort. At first it was used every other day, in sufficient quantity to produce a reaction; in a few weeks it was used every third day, and later every fourth day, until after six months it was used only once a week. The patient now weighs 120 pounds, and there is only just a suspicion of the tumor left.

Dr. Jacob A. Fulton, Astoria, reported a case of fibroid tumor of the abdominal wall on which he operated 16 years ago. At that time he considered it a rare disease for he found few reported cases. In its removal a portion of the peritoneum about the size of a dollar was removed and although the patient had secretly eaten a large number of dried prunes before the operation, and vomited prunes in large quantities, the operation was successful and no hernia followed. There has been no return of the disease.

Dr. L. L. McArthur, Chicago, mentioned one case of this type which well illustrates the difficulties of diagnosis. The growth was so mobile that it was transferred from the gynecologic to the surgical department of the hospital. On opening the abdomen Dr. McArthur found a tumor with a broad, flat ribbon-like base extending from nearly the umbilicus to the symphysis. He thought that he had to deal with a long pedunculated uterine fibroid. The interne, in his bi-manual manipulation, had been able to detect that when the tumor was pushed down the abdominal wall was also dragged down, especially under the right rectus.

Dr. Maurice H. Richardson, Boston, stated that Dr. Willoughby's reference to Coley's treatment brought to his mind an inoperable case of fibrosarcoma of the abdominal wall so successfully treated that a hernia developed in the scar of exploration through a space occupied originally by six or eight inches of dense tumor. Dr. Richardson has seen several cases of fibroid tumors of the abdominal wall. Whether they were of the desmoid variety or not, he cannot say. The practical point in the treatment of any neoplasm extensively involving the abdominal wall is the closure of the gap left by its removal. He has recently succeeded in filling in the gap left after removing the muscles of the left lower quadrant, which, with a portion of the os pubis, had been involved in the fibrosarcoma of great extent. The muscular belly of the tensor vaginæ femoris, with the fascia lata, was reflected from the thigh and sutured to the edges of the gap, as shown by these blackboard drawings. A firm and serviceable abdominal wall has resulted.

Dr. Charles A. Powers stated that it is difficult to distinguish between certain types of fibromata and sarcomata, and that the best that can be done is to get a reliable pathologist's report on the tumor. Dr. Powers stated that his paper dealt only with fibromata. In referring to Dr. Richardson's case Dr. Powers quoted Dr. Jacobi of New York who reported a case of extremely high temperature which he had observed; a number of men disputed the accuracy of his observation whereon Dr. Jacobi said that when the clinical facts collide with previously existing scientifific knowledge the latter goes to the wall and the facts stand. Dr. Powers said that he is quite ready to accept Dr. Richardson's conclusions.

CYSTS OF THE SPLEEN.*

W. A. BRYAN, A. M., M. D.
NASHVILLE, TENN.

Splenic cysts, unaccompanied by cystic formation in other structures, do not often occur. The classes found are: 1, Dermoid cysts, one of this type being reported by Andral; 2, simple, serous, or blood cysts, of which a few cases have been reported; 3, echinococcus cysts. Although the latter usually occur in association with similar cysts in other organs, there are reported, according to Coen, as quoted by Douglas, 61 cases of solitary splenic cysts, although the spleen is involved in only from 1 to 3 per cent. of human echinococcus.

The etiology of cysts of the spleen in the case of dermoids and echinococcus may be summarily dismissed with the statement that it is the same as in other structures. Simple serous or blood cysts are of more interest. They are called by the last name of the three by certain authors from the fact that they are all thought to occur from an extravasation of blood within the organ or its capsule, the sanious contents remaining indefinitely or being replaced by a fluid, sometimes clear, sometimes straw-colored. Others, however, attribute the serous and the blood cysts to different causes. Andral reported a case of simple serous cyst in the center of the spleen, and Leudet a multilocular cyst in a spleen that was not enlarged. Boettcher found a multiple serous cyst in an amyloid spleen and noted that some of the

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

cysts were traversed by fine trabeculæ of connective tissue. He attributes the cause of these cysts to occlusion of the arterioles, due to the amyloid change with fatty degeneration and ultimate softening and sloughing of the splenic parenchyma. For the most part, however, we can say that serous cysts in the spleen are formed precisely as elsewhere. The enlargement and the associated changes accompanying chronic malaria seem to favor the formation of splenic cysts, as is shown in the case of Livois, Marcano and Ferecol, Spencer Wells, H. C. Cutcliffe, Giuliano, and myself.

Blood cysts are found more frequently than simple cysts, and essentially follow hemorrhage into the splenic substance or, as happens in the majority of cases, just beneath the capsule. This variety of cyst forms more rapidly than any other, in the nature of the case. However, full development is not necessarily reached early. In Credé's case ten years intervened between the time of traumatism and of operation. Irregular development is seen in some of them, periods of rapid increase alternating with periods of quiescence, caused by additional hemorrhages.

Cysts of the spleen contain a capsule, lined with endothelial cells, except dermoids, which are lined with epithelium. The capsule is made up of fibrous tissue containing now and then unstriped muscle fibers. In Foerster's case the cyst was surrounded by cartilage. Hydatids give us a more complex capsule, externally is a more or less complete layer of fibrous tissue, adventitious in origin, the cuticular membrane separating, as it were, the structure of the containing organ from the echinococcus capsule proper, the endocyst. This inner wall collapses and curls up when removed, has a characteristic lamination of seven or eight layers, and has a gelatinuous appearance. The endocyst has an external wall and an internal, the former having the appearance of "highly elastic, lamellar cuticle," the latter that of "granular matter, cells, muscle tissue (unstriped), and a water-vascular system," according to Sutton. Extending from the lining of the hydatids we expect to find daughter cysts, although it is a well-known fact that they are not uniformly present.

The simple serous cyst contains a fluid varying from clear colorless to straw-colored. In this fluid are to be found sometimes a small amount of débris from more or less completely broken down cells. The specific gravity varies from 1000 to 1028 or 1030, and Ruess has formulated a table to determine the amount of albumin approximately from the weight of the fluid, the essence of which may be stated thus: Below 1008 there is little or no albumin; at 1008 the albumin is 0.2 per cent., and for each point of increase in specific gravity there is between 0.3 per cent. and 0.4 per cent. increase in the amount of albumin, being nearer 0.4 per cent. than 0.3 per cent. For example, at 1008 the amount, as stated above, of albumin is 0.2 per cent.; at 1009 it is 0.6 per cent.; at 1010 it is 1.9 per cent.; at 1011 it is 1.3 per cent. It must be remembered that hemorrhage into a simple cyst will give contents similar to an original hemorrhagic cyst and will thus produce confusion as to the original nature of the fluid. However, it is claimed by some, as mentioned already, that the simple cyst of the spleen originates from hemorrhage.

Blood cysts of the spleen have been found far more frequently than simple cysts. Yet, as Loomis and Thompson claim, it is probable that some of these are simple cysts into which bleeding has taken place. The same characteristics of fluid are seen that blood may assume when long confined anywhere in the body. The color of the fluid is black, brown, reddish yellow, red or yellow, and if the cyst is of long standing the contents vary in consistency according to the extent of absorption and the abundance of serum.

In reviewing the cases of cystic spleen exclusive of echinococcus it is found that the contents vary largely in the proportionate distribution of the chief constituents. The fluid is degenerated blood in most cases and may contain red and white blood cells, cholesterin crystals and shreds of tissue. A case reported by Pean had calcareous granules in the fluid. Terrier's case had blood clots which brightened on contact with oxygen. Piccinelli reports an ossified cyst of the spleen. It is rare to find a splenic cyst in which the greater part is made up of cholesterin. Andral, in 1829, found a splenic cyst with fibro-serous walls whose interior contained fatty matter, like tallow, in the midst of which some hairs were scattered. This has been classified as a dermoid cyst.

Echinococcus fluid is clear, free from albumin, neutral or alkaline in reaction and of a specific gravity of 1004 to 1010. Small amounts of grape sugar and albumin are at times found, but the specific gravity, according to Ruess' table, can not allow large percentages of albumin. Inorganic salts occur in considerable amounts, while inosit and succinic acids are occasionally seen; traces of urea and creatin have also been found. Boinet and Chazoulier discovered and isolated the toxic ptomains of this fluid. The best evidence is in the hooklets and scolices of the parasite. Besides these there are observed at times shreds of faintly yellow membrane. These alone constitute a positive diagnosis of hydatids, and yet these microscopic findings are not always present. Virchow was the first to recognize the true nature of echinococcus multilocularis which had theretofore been accepted as colloid carcinoma. Numerous small round cavities filled with a gelatinous fluid constitute in the aggregate a large mass resembling a tumor. The central cavities are often found broken down, or fused, as it were, into a large cavity. Here scolices are rarely found. Daughter cysts become separated occasionally from the maternal growth and lie loose in the fluid, escaping, it may be, in great quantities with the liberated contents. When the primary cyst produces no buds, it is called acephalocyst.

Cysts of the spleen, when small and uncomplicated, present no symptoms and pass unnoticed to the postmortem table or to the grave. When, however, complications or considerable size become features of such a cyst or cyst group, then physical signs and symptoms are present, although they are, by no means, always clear enough to make a diagnosis. Out of seventeen cases in which attempt was made to show some previous or present possible etiology there were five cases preceded by traumatism, five by malaria and two by both. One patient died of mitral affection and two of Bright's disease. One patient developed the initial symptom during an attack of mumps. One developed immediately after parturition, and a second followed parturition, succeeded shortly by trauma. So that we see seven out of seventeen had a history of malaria, in some of whom enlargement of the spleen had been recognized before the cyst formed; and eight, not including one parturient patient, had traumatism over the spleen. Where sex is mentioned the division is equal. The youngest patient having simple or blood cyst was 7 years old. The patient, if the cyst be large enough to call his attention to the fact that a tumor is present, gives a history of the first appearance being in the left hypochondrium and growing down from under the ribs. This he may reduce with more or less completeness back into the original site, but such restoration is, of course, limited by the size of the growth and the extent and density of adhesions. Out of eleven cases of simple and blood cysts only two were fixed. Recognition of cyst development in a misplaced or wandering spleen would be a practical impossibility unless diagnosis of the wandering spleen had been made before cyst formation had begun. In Bardenheuer's case the spleen was in the pelvis. Pressure symptoms and those produced by dragging are the chief subjective evidence that anything has gone wrong. Adhesions aid these in producing symptoms in the case of echinococcus. The habits of a patient or his place of abode may give beneficial help to determine echinococcus, but these have no bearing on simple serous or blood cysts, except in so far as malaria is a causative agent. Nausea and vomiting, together with pain in the left hypochondrium, occur. By pressure, retention of the feces or obstruction of a ureter occurs, or pressure against the diaphragm, heart and lungs is so intense as to produce dyspnea. Some of the cases have had severe colics and some have developed ascites and edema of the legs. Mosler has stated that pain is an early symptom in echinococcus of the spleen, beginning in the left hypochondrium and extending into the lumbar region. In Martineau's case pressure of the enlargement on the lumbar plexus caused pain in the left lower extremity, diminished tactile sensibility and flexion at the hip joint.

The tumor, if large enough to palpate, is found to be movable and easily reducible into the original splenic site in all of those cases of cysts which have not become inflamed and adherent or which are not too large, and in echinococcus which habitually produces more or less peripheral adhesions to adjacent structures so that we may not be surprised to find it thoroughly immovable by manipulation and respiration, and we rarely expect to see it movable without any limitations except the normal supports of the spleen.

The growth may present a fluctuating mass or, if echinococcus, may give the hydatid thrill, but by no means constantly. This is absent in 50 per cent. of cases, especially in solid or deep cysts, and it appears in other conditions, viz., ascites and ovarian tumors, some authors claiming higher frequency for it in the latter conditions. Hence, its diagnostic value is little. The surface may be smooth and even or give a lobulated presentation to the hand, caused by multiple or multilocular cysts.

On aspiration the fluid found will give a clue to the diagnosis. But when suppuration has occurred the characteristics are so obscured as often to be worthless. If there is any probability of such a cyst being hydatid or having suppurated, aspiration should by no means be resorted to for diagnostic purposes.

Differential diagnosis may be made between cystic spleen, on the one hand, and, on the other, abscess of the spleen, ovarian cysts, pancreatic enlargement, hydronephrosis, cysts of the mesentery, and hypertrophied spleen as found in malaria and leukemia. The site of the tumor, the direction of its growth, its attachments or, what amounts to the same thing, the directions in which it may be moved, the pressure and traction symptoms, the constitutional condition of the patient at the time and prior to the beginning of the growth taken together make it possible in some instances to differentiate correctly in these rare cases. In others, even the majority, the surgeon simply will recognize that he has a surgical condition, changing or confirming his first opinion on opening the peritoneum.

Spleen cysts last for years without producing symptoms, remaining *in statu quo*, or gradually or suddenly attaining large size. Echinococcus cyst may terminate by complete disappearance, due to death of the echinococcus or to deprivation of nourishment from calcification of the walls; the more usual termination, however, is by suppuration, or rupture, which may take place into any hollow viscus and allow escape of the fluid, producing a cure; or perhaps into the pleural cavity, causing violent symptoms and even rapid dissolution, or into the lung. The escape of hydatid contents into the body cavities is capable of producing secondary hydatids, as demonstrated by Martin's case. His patient, 37 years old, had had hydatids of the liver ten years and felt something give way in the upper abdomen. Shortly afterward he had pain in the back and the epigastrium, nausea, vomiting and rapid emaciation. On operation the cyst was found ruptured and both visceral and parietal peritoneum were covered with hydatids from the size of a nut to the size of a hen's egg. Though serious, perforation into the peritoneal cavity is not always fatal. Skoda narrates a case in which the principal symptoms were pain, rigors, wiry pulse and cyanosis. Patient recovered.

Henoch claims that the urticaria which sometimes follows the removal of the fluid is due to escape of a few drops into the peritoneal cavity.

The final outcome of cysts of the spleen varies with the type of cyst and the course it pursues. Small simple cysts cause no trouble. Larger cysts produce a more unfavorable prognosis. Blood cysts are more prone to grow, owing to repeated hemorrhages occurring within them. Echinococcus may rupture into a viscus and escape to the outer world, producing cure, or into an internal cavity resulting in death. When abscess formation follows a cyst the prognosis is that of the former. Complete cure follows these cysts rarely, by absorption, shrivelling and calcification of the capsule. This happens in echinococcus only when the tenia is dead, not invariably then.

I lay down as the first rule for treatment that these cases should be operated on by incision, not by puncture, if the cyst is large enough or is producing symptoms enough to demand treatment; I might more correctly, I believe, say if the cyst is sufficiently large to produce clear physical signs, whether the cyst belongs to one or the other variety, for in absence of hydatids elsewhere one can not make accurate differential diagnosis between them. Splenectomy is to be done in those cases in which the organ is so perfectly destroyed as to render it of no further service and not so completely adherent that its removal becomes hazardous. In cases where the spleen is not absorbed and in those where manifestly it can not be removed with safety, the better procedure will be to drain the sac after suturing to the abdominal wound. Giuliano, in an article on blood cysts, states that diagnosis can not be accurate, and then advises either puncture or celiotomy, leaning to the former, if one may judge from the text. Splenectomy, he says, is not warranted in this class. In his researches he has found 15 cases besides his own. Excision of the spleen seems to me a far more judicious operation than simple removal of the diseased area. Hemorrhage can not fail to follow the latter far oftener than the former.

Tapping, injections and excision have no field for usefulness; the treatment must be splenectomy or open cyst drainage. If, however, one can sufficiently assure himself that the cyst is serous or hematic, then aspiration once or twice cures; and, if on reaching the spleen and aspirating, there is no doubt of the condition, a cure may be relied on if all the fluid is removed and the wound closed.

I could find records of eleven patients with serous or blood cysts treated by aspiration, all of whom recovered; eight cases of splenectomy, including my own, in all of which cure followed. One patient was marsupialized after curetting, cured; four patients were treated by injection of caustics, two of whom died; two patients were treated by resection and cautery, both recovering.

My own case is as follows:

REPORT OF A CASE.

History.—Mrs. H. L. S., white, age 39, came to me November 24, 1904, being referred by Dr. J. H. Laws. Patient is American born, housewife. Her father died at 61 years of age of apoplexy. Remainder of her father's family living in good health. She is the mother of six children and had no disease except those of childhood, and "fever" when small. Three years ago she had tertian chills for a period covering about one year. In August, 1903, she first noticed an enlargement in her left hypochondrium, which gave her no pain until the spring of 1904, although it grew steadily. She complained of pain under the left scapula which ran forward and down the left side. Oppression in the region of the heart. The pain under the scapula was increased by pressure on the tumor. There was a dragging, pulling sensation in the hypochondrium. She had noticed an increasing shortness of breath on exertion; this had not been present previous to the development of the tumor. She had lost 14 pounds weight in the past year. She has, for the last month, had considerable nausea and vomiting.

Examination.—There was present on examination an enlargement extending from the margin of the ribs at the left hypochondrium to within three or four inches of the pubic arch. Fluctuation was present, the mass was fairly movable, moved on respiration, and could be reduced into the space underneath the left margin of the thorax, but escaped immediately on removal of the hand. There was no leucocytosis.

Diagnosis.—Multilocular cyst of the spleen.

Operation.—The abdomen was opened through the left linea semilunaris, the incision being six inches long. The cyst was more easily approached through the transverse mesocolon, owing to adhesions between this structure on its upper surface and the spleen. The growth with the spleen was removed without being opened; but on cutting the vascular attachment and attempting to lift the tumor out of the abdomen, cystic fluid escaped through one of the vessels and dropped into the pocket whence the tumor was removed. Hence, not knowing but that I had echinococcus to deal with, the edges of the space were sutured to the wound, which was drained for a few days. The patient left the hospital on the twenty-first day, entirely recovered.

The cyst wall was at places very thin; there were several large pockets intercommunicating, and the splenic substance was obliterated except an ounce or two. The cystic spleen weighed two and one-half pounds. The fluid was clear and colorless. Specific gravity 1006, contained no scolices or hooklets and no albumin. The lining of the cavity contained no epithelial cells and was smooth and glistening and easily separated from the surrounding tissue. The wall was laminated fairly well and contained white fibrous and a small amount of unstriped muscle tissue.

This was, it seems, a case of simple cyst of the spleen and the only etiology discoverable was the fact of a long siege of malaria preceding the formation. I have been unable to determine the connection between cysts of the spleen and enlargements due to malaria.

REVIEW OF CASES OF SPLENIC CYSTS.

Without presuming to make a rigid classification, I give below a brief review of the cysts of the spleen covered in the literature.

DERMOID CYST.

1. Andral: Dermoid. Fibro-serous walls: containing a fatty matter, like tallow, and hairs scattered throughout.

SEROUS CYSTS.

1. Garcia: Man, age, 36, syphilis six years ago, tertian fever cured by quinin; fall from horse causing contusion of abdomen followed soon; one month later localized pains in abdomen; digestion poor, enemas required. Tumor in left hypochondrium, which grew still another month. Puncture liberated odorless gas and tumor diminished; next day second puncture liberated quart of fluid color of white wine, clear, transparent sp. gr. 1004, contained albumin and sodium chlorid. Another puncture after three months, 300 grams; cured.

2. Gauget: Laborer, age 46, alcoholic history, dyspnea on exertion for some months. Symptoms of asystole. Died in collapse. Autopsy: Spleen slightly enlarged and contained yellowish liquid in rounded regular pocket size of hen's egg, and a second the size of a walnut.

3. Leudet: Multilocular serous cyst: volume of spleen normal, surface normal. Cavity of four or five cells in splenic tissue; fibrous wall pavimentous endothelium, and contained serous liquid. This was in a woman 60 years old, who had mitral affection.

4. Foerster: Serous cyst of spleen with cartilaginiform wall seen in the collection at Wurzburg.

5. Crede: Man, age 44, pain five days following trauma over spleen. Tumor size of fist one year before operation in left hypochondrium; grew rapidly to size of fetal head fluctuant, mobile fixed at upper part; confused with hydronephrosis. Splenectomy. Cured. Fluid yellow, limpid, with numerous cholesterin crystals.

6. Mattei: Autopsy: Man, age, 68; spleen weighed 370 grams; tumor size of orange, calcified at points on surface, cartilaginous at other points. Fluid yellow, transparent, contained albumin. The central cyst was size of turkey's egg and had seventeen smaller ones surrounding it. Under microscope, cholesterin, formless masses of lime salts, granulous globules and proteid detritus.

7. Wilks. Old woman died of Bright's disease. Cysts also in kidneys. Cysts of spleen size of walnut and a few smaller on surface. Lined with smooth membrane and contained serum. Says another similar specimen from a man who died of Bright's disease is in Guy's museum.

8. Klippel & Lefas: Man, age 71, attacked long ago by paretic phenomena of four extremities. Autopsy: Spleen weighed 235 grams, and contained a cyst the size of a large walnut, enclosing a clear yellowish liquid, a second cyst size of small walnut, easily enucleable.

9. Boettcher: Multiple serous cyst, amyloid spleen, cysts varied in size from flaxseed to pea, some of them traversed by [illegible] æ. Lined with single layer of flat en[illegible] thought, to occlusion of arterioles, from [illegible] their walls, with fatty degeneration [illegible] in parts of spleen pulp.

HEMATIC CYSTS.

1. E. Bocchia: Male, age 24, traumatism over spleen six years ago; pain for some days. Had had present disease three and one-half years. Pains increased with tumor in left hypochondrium. Diagnosis splenic tumor. Puncture. Cured. Dense chocolate-colored liquid, alkaline, and had physico-chemical characteristics of blood. Evacuation next day by incision under cocain, on reaching cyst drew off 2,140 grams of fluid by trocar. Sutured wound. Healing per primam.

2. W. Minervini: Woman, age 44, robust multipara; tumor larger than adult head, in lower abdomen. Immovable. Fluctuating. Laparotomy. Splenectomy. Sero-hematic cyst in ectopic spleen. Claimed to be second thus far observed. Recovery.

3. Porge: Purulent hematic cyst, size of walnut; cyst cavity enucleated, wall thick, fluctuant, yellowish gruelous odorless fluid. Numerous red globules; globules of pus and cholesterin crystals in fluid. From the report I judge this was found postmortem.

4. Baccelli: Woman, age 27; married three years, pregnant four months. Two months' back traumatism over spleen. Pains after four days, which grew worse. Tumor of left upper quadrant, fluctuant, moved with diaphragm. Diagnosis cyst of spleen, from direction of growth, its connections, and movement on respiration. Two punctures and drawing off hematic fluid. Cured.

5. G. Chavier: Soldier, constipated three days, with some colics; abdomen somewhat ballooned. Put to bed, dieted, given sod. sulphat. That night had violent abdominal pains. Purging had no effect; passed no gas during day. Kicked over spleen seventeen months before by a mule. Died. Autopsy: Much foul gas on incising peritoneum; cyst of spleen, size of a Savoy biscuit, rested on anterior surface of stomach. Not adherent. Contained reddish brown extravasation between capsule and splenic substance; 1,870 grams of fluid. In pocket was organizing brownish fibrous deposit.

6. A. Heurtaux: Woman, age 27, single [illegible] years ago. Pain continued in left side sc[illegible] mor a year afterward size of fist, not [illegible] had grown regularly since, till now it c[illegible] left side of abdomen. Fluctuating. Di[illegible] cyst supposedly hydatid. Laparotomy: ([illegible] by serous leaf covering it. Drew off 9¾ liters, opened, curetted, irrigated, marsupialized and drained. Recovery. Fluid contained blood cells, leucocytes, granulo-fat cells and cholesterin.

7. Livois: Man, age 46. Had severe intermittent fever four years before: tertian. After first attacks had pains in left side and noticed tumor, which grew to large size; fluctuated. Diagnosis cyst; connections not determined. Entered hospital for ulcer of leg. Did well and asked to be released. Eleven days

from entrance had violent colics, vomiting and diarrhea and died in three hours. Autopsy: Much reddish serous fluid in peritoneum. Cyst of spleen, size of ostrich egg, was found. It contained a great quantity of rosy matter, filamentous, and had much affinity with fibrin. Weight of spleen and cyst, 7 pounds. Liver was enlarged and stomach distended with greenish liquid.

8. Pean. Woman, age 20, single. Two years ago had a swelling in the hypogastric region, with pains. Symptoms gradually increased, and became very violent two months before operation, finally unbearable. Tumor in hypogastrium like full term gravid uterus, but fluctuated. Opened abdomen, punctured, drew off 3 liters of thick viscous yellowish fluid. Removed most of cyst and spleen and cauterized remainder. Recovery. Fluid contained albumin, leucocytes, red blood cells, cholesterin and calcareous granules.

9. Pean & Rousset: Girl, age 7, sero-sanguinolent cyst. Diagnosed by puncture. Treatment by caustic. Death two months from beginning of treatment followed by injection iodin, from acute peritonitis.

10. Marcano & Ferecl: Man, age 31, malaria three consecutive years. Three years ago spleen became voluminous, causing dyspepsia. Colics two years ago, dyspepsia, nausea and vomiting after eating. Symptoms again at end of two years, but became better, and recurred after another year. Tumor in epigastrium and left hypochondrium, fluctuating, spontaneous pains not increased by pressure. Puncture, resulted in drawing of 300 grams fluid, chocolate colored, viscous and containing blood cells. Treated by injection of iodin and permanganate of potash, one or other three times a day.

11. Quintard & Pean: Woman, age 53. hematic cyst, treated by caustics. Death some days after opening pouch, due to splenitis and acute peritonitis.

12. Knowsley & Thornton· Girl, age 19. Painful tumor in left side two years, grew rapidly, fluctuating, movable. Diagnosis doubtful, but spleen was eliminated from low position. Splenectomy. Fluid reddish serous with cholesterin. Recovery.

13. Spencer Wells: Woman, age 21, married; at four years had intermittent fever lasting two years. Hypertrophy of spleen. Married at 19 years of age. After one year had diagnosis of ovarian or periovarian tumor. Another diagnosed tumor of left ovary. Had normal labor same year. Tumor descended, not attached to ovary, freely movable. Wells diagnosed hypertrophied spleen. Patient grew much worse. Diagnosis corrected by puncture. Cyst broke during operation, and contained 4 or 5 liters of reddish brown liquid, which showed red globules and leucocytes. There were numerous adherences. Incomplete removal. Cured.

14. Ferrier: Woman, age 33, married twelve years, three children. During attack of mumps one year previous had pains in left side of abdomen, which became larger, growth and pain persisted, tumor to left of umbilicus, size of fist, movable and had large pedicle from hypochondrium. Diagnosis cyst, perhaps hydatid of epiploon or spleen; examination was painful. Laparotomy, excision and cautery. There were many adherences. Contained fluid blood clots, black, but becoming red in atmosphere. Cured.

15. Verneuil: Said he had seen four cases of hematic cysts, three of which were cured by trocar.

16. Chalite: Woman, age 36, had dyspnea, heaviness and abdominal pains. Two years before after parturition swelling of abdomen and edema of legs, abdomen enormous, left side more prominent. Tumor hard, painless, mobile rising below left false ribs. Diagnosis cyst of spleen, possibly hydatid. Splenectomy. Eight liters of brown liquid, in which rags of splenic tissue floated. Cured.

17. Mareschi & Ghetti: Woman, age 42; severe pains in left hypochondrium twelve days after eighth parturition, lasting four or five hours, ceased after twenty-five days. Nine months later pain returning while carrying heavy object: four months later traumatism over spleen, and soon noticed small painless tumor that grew rapidly. It was movable, elastic, fluctuant. Splenectomy. Weight, 1,315 grams, contained blackish limpid liquid showing white and red cells. Recovery.

18. Barbacci: Autopsy: Found cyst of spleen size of hen's egg. Transparent viscid fluid, color of gold flowed, coagulum of fibrin in pocket. He found a second cyst size of a lentil with similar fluid, alkaline and albuminous. He called this a lymphatic cyst.

19. H. C. Cutcliffe: Male, age 40, had intermittent fever four months and enlarged spleen. Twelve days ago swelling in left side under ribs, preceded two or three days by acute hypochondriac pain. Tumor hard and free from tenderness; after five days seemed to fluctuate. Punctured. Found degenerated blood. Cured.

20. Spillman: Man, age 51, sick three days; this appeared suddenly, with violent shivering in left side, followed by a dry, painful cough, dyspnea. Died in ten days. Autopsy: Spleen contained cyst size of fetal head, contained yellowish liquid, cholesterin, fluid red by transmission. Density of water. Analysis proved to be hematic.

21. Giuliano: Man, age 33, Malaria for some years, six months before coming to Giuliano had trauma of left hypochondrium and felt intense pain. Large tumor in left hypochondrium, connected with spleen. Puncture liberated degenerating blood. Recovery.

22. Baginsky: Girl, age 13, cystic tumor connected with spleen, resulted from trauma and increased gradually. Puncture brought 2 liters of red brown liquid containing many red corpuscles.

Below I give another group not definitely classified by the men who found them.

1. Piccinelli: Priest, age 67, digestive disturbances thirty years before. In time oppression in epigastric region. Sharp, darting pain behind left hypochondrium five years ago while at a banquet, and extended to splenic region, where it remained. Became worse with complications till death. Autopsy: Spleen in place, undersize, contained a hard tumor larger than hen's egg, situated at the hilum, and full of knobs. Incised with difficulty and viscid gelatinous fluid came out: an ossified cystic tumor.

2. Giovinardi: A pathologic specimen, consisting of a cyst cretified in its walls, which he found in the spleen of a cadaver. It contained an albuminous liquid which effervesced in hydrochloric acid. Cyst was the size of a small nut.

3. J. H. Haswell: Man, age 57, died of cancer. Fullness of noticed before death. Fluctuation. Con- small amount of whitish débris, showing globules, cholesterin and a few granular red cyst weighed 3¾ pounds. On opening, a semipultaceous matter exuded, mostly in rounded masses of a dirty yellow; among these were round, jelly-like globules, the size of a walnut, from which puncture brought a clear fluid. No booklets or scolices were found nor any dermoid structure. Haswell calls this a mucous cyst. Almost certainly it was echinococcus.

4. Bardenheuer: Woman, age 47, a few months previous had vivid pains in left hypochondrium. Tumor appeared and was diagnosed cyst of ovary. Bardenheuer saw patient six months after beginning of pain. Tumor in pelvis size of infant's head, pushed uterus slightly to right. Slightly movable. Diagnosed cyst of left ovary. Exploratory incision. Resection and cautery. Recovery. Contents not given.

INDICATIONS FOR THE REMOVAL OF THE PATHOLOGIC SPLEEN.*

BYRON B. DAVIS, M.D.,

Professor of Surgery College of Medicine, University of Nebraska; Surgeon to Immanuel and to Wise Memorial Hospitals.

OMAHA, NEB.

Case 1.—Miss S., clerk, aged 40, presented herself at the clinic of the University Medical College January 27, 1904, with the following history:

History.—Family history negative. One year ago she had German measles. Two weeks later she contracted a severe cold which lasted two weeks, and she has not felt well since. She is prone to headaches and becomes easily tired. For past six months she has complained of languor and weariness on slight exertion; also of a nausea, faintness, shortness of breath and occasional sharp pains in her left side near the costal arch. In November, 1903, she discovered an enlargement in the left upper quadrant of the abdomen extending below the arch of the ribs. She was able to continue her occupation, that of clerk in a dry goods store, until December, 1903, when she was compelled to stop it on account of the increasing muscular weakness and her inability to stoop because of pressure and soreness caused by the abdominal growth. She has never lived in a malarial district.

Examination.—She is a small woman of an anemic appearance, somewhat emaciated. A firm tumor is to be felt in the left upper quadrant extending to the median line; it moves with respiration and cannot be pushed up under the ribs. The condition excited Dr. Thomas Truelson's suspicions and he made a blood count which is recorded as follows:

Reds	3,968,000
Whites	9,600
Polynuclears (per cent.)	77
Small lymphocytes (per cent.)	17
Large lymphocytes (per cent.)	5
Eosinophiles (per cent.)	1
Hemoglobin (per cent.)	37

The heart was somewhat more rapid than normal, lungs and liver were normal. Dr. Truelson felt justified in making a diagnosis of splenic anemia and put her on medical treatment and made numerous blood counts. I am greatly indebted to Dr. Truelson for the benefit of his careful and frequent clinical records extending over a year.

In the summer of 1904 I saw her and the condition was about the same.

Later History.—Early in January, 1905, she became shorter of breath, more nauseated, had considerable rise of temperature for a period of two weeks, with pain in the region of the splenic enlargement, and distinct tenderness on pressure. The mass now became distinctly larger and was less movable than before. She also complained of increased difficulty in stooping, evidently because this caused pressure of the mass between the posterior bony wall of the abdomen and the arch of the ribs in front. For some time she had complained of a dry cough which she said seemed to be excited by a dragging or pulling sensation at the lower part of the left lung. There was no hemorrhage from the mucous membranes or diarrhea.

After she had recuperated from her febrile attack the question of splenectomy came to the fore with more force, since she seemed to be losing ground and it was realized that to wait longer would only increase the risks of a successful operation.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Operation.—February 23, 1905, it was decided to send her to Immanuel Hospital for operation. The enlarged spleen at this time extended to the level of the umbilicus, and two inches to the right of the median line. The patient was more emaciated than at the beginning, weighing 95 pounds and for several months the characteristic bronzing of the skin had become more and more noticeable.

On the day of the operation the blood count was as follows:

Reds	3,936,000
Whites	15,600
Hemoglobin (per cent.)	38

The patient was operated on February 25, 1905, at Immanuel Hospital, in the presence of the students of the College of Medicine of the University of Nebraska and several visiting physicians; the spleen was removed. An eight-inch incision was made through the left rectus muscle from the ribs downward, separating the fibers of the muscle. Universal adhesions were at once apparent fixing the hypertrophied spleen to all the surrounding viscera. Remembering the unfavorable prognosis under such conditions the removal was done with the utmost caution. By ligating the vascular adhesions in two places and then cutting between the ligatures a remarkably small amount of blood was lost. The gastro-splenic ligament was treated in the same manner. Finally, by turning the spleen toward the left the vessels of the pedicle were ligated with silk, separately, and the removal was complete.

Large gauze pads wrung out of very hot water were pressed into the cavity formerly occupied by the enlarged spleen and this very soon stopped the slight oozing. The abdominal wound was closed and the patient put to bed with considerable shock, from which she soon rallied.

Result.—Her convalescence was uneventful. There was no fever and no increase in the pulse which remained almost constantly at from 80 to 84 beats a minute. She was allowed to sit up on the sixteenth day and to leave the hospital in three weeks.

Examination of Spleen.—The hypertrophied spleen was found to weigh six pounds and one ounce. It was lobulated, the edges were rounded and on the cut surface large necrotic areas presented themselves, the appearance being suggestive of sarcoma.

Subsequent History of Patient.—Very soon after the operation the patient began to gain in weight and the last I heard from her, May 25, three months after the operation, she wrote that she had gained 25 pounds. Her faintness, shortness of breath, muscular weakness, etc., have been steadily less marked. The bronzing of the skin began soon to disappear and when she left Omaha, two months after the operation, her skin had lost all trace of it.

A leucocyte count the day following operation showed 27,-000 leucocytes. The further detailed report will be published by Dr. Thomas Truelson, who has worked out the clinical and pathologic data in the most thorough manner, to whom I wish to express my thanks.

FUNCTIONS OF THE SPLEEN.

Until the physiology of an organ is known its pathology is likely to be elusive. On the other hand, a study of its pathology is often rewarded by a clearer knowledge of its physiology.

Regarding the function of the spleen about all that can be definitely stated is that it belongs to the hematopoietic system. The exact nature of its function is yet conjectural. That it manufactures white blood corpuscles, that it breaks up and destroys the reds, and that the splenic cells liberate hemoglobin, which passing to the liver is there transformed into bile pigment, are some of the functions commonly associated with the spleen.

That all these functions are performed by the spleen, in the light of recent observations, is inconceivable. Against the time-honored opinion that the lymphoid tissue of the spleen manufactures white blood corpuscles and destroys the reds is the undisputed fact that during the first few days after the spleen has been removed the number of leucocytes increases more than 100 per cent., while the number of red blood corpuscles is considerably diminished.

If a factory having almost a monopoly in the manufacture of a certain commodity be burned, there would scarcely be likely to be an immediate increase of that article on the market. The logical deduction is that instead of elaborating white blood corpuscles the spleen destroys them, and the decrease in the reds points to the spleen as their manufacturer—not as the place of their destruction.

These deductions support the opinion of Vulpius that the spleen transforms the whites into reds. Vulpius reached this conclusion by observing that when the spleen is congested by natural or artificial means the blood habitually contains a maximum number of reds and a minimum number of whites.

Williamson[1] found that by a special method of staining he was invariably able to determine nucleated red blood-cells, many of them in a state of nuclear division, in spleen smears of hogs and cattle. The same observation had previously been made by Arteaga,[2] of Havana, using the spleens of cats and dogs. In fact, most of the experiments of recent years lend support to the opinion that in vertebrates the function of the spleen is the manufacture of red blood corpuscles.

That the spleen is an important elaborator of the blood directly or through the medium of an internal secretion which performs that function is further proved by the well-known fact that an acute anemia caused by hemorrhage is always followed by a temporary enlargement of the spleen, due no doubt to an extra amount of work being thrown on it in an effort to make good the loss. If its function was to destroy red blood corpuscles and to elaborate leucocytes would there be need of an increase of its function?

If we adhere to the orthodox opinions, the opinions laid down by the text-books on physiology, we would *a priori* expect splenectomy to induce immediately a great decrease of the whites and an increase of the reds, a phenomenon directly the opposite of that universally observed. Continued careful observations of the blood changes in pathologic conditions of the spleen, as well as of the condition of the blood after splenectomy, are likely to place the physiology of this organ on a securer basis than the purely speculative one of the physiologists.

One of the most attractive fields for physiologic research is along the lines of the internal secretions. It is not necessary to believe that all the influence the spleen exerts is carried out within the organ itself. A toxin or toxins may be elaborated by the splenic cells, which, passing into the circulation, may exert a profound influence over the elaboration of the blood. Although certain blood changes may, and probably do, occur within the spleen, they may be of only minor importance. The major function may be the production of a powerful chemical agent which is projected into the circulation and does its work within the vascular system.

SPLENECTOMY.

In the history of the development of splenectomy as a surgical procedure numerous mistakes have been made. Ignorance of its physiology has led to much blind groping to learn something of the pathology. Many spleens have been removed that should not have been treated surgically and many fatalities are to be charged to insufficient knowledge of the limitations of splenectomy as a curative measure.

---

[1] Williamson: Amer. Med., June 3, 1905.

[2] Arteaga: Amer. Med., May 14, 1904.

The border lines between the conditions that may be dealt with surgically and those to be left untouched are becoming better defined though not yet as definite as would be wished. Every item that may aid in increasing the knowledge of the physiology and pathology of this organ, as well as to clear up points in diagnosis is of the greatest value. Unfortunately, the blood-findings before and after splenectomy have been completely recorded in only a few instances.

The discussion of the immediate and remote results of removal of the spleen has been so largely entered into and so recently by such men as Warren,[3] Harris,[4] Bessel-Hagen[5] and many others that it will be passed over briefly. A few well worked out facts may be enumerated. Almost without variation, splenectomy is followed by a marked leucocytosis, the number of leucocytes increasing daily until the maximum is attained in from ten days to three weeks, when there is a gradual diminution and in from four to six months they reach normal again.

The number of red cells, on the contrary, is diminished though in a less proportion and normal is not usually reached until six months or more after the spleen has been removed. These facts seem to show that although the function of the spleen may be performed by other tissues, this vicarious power is gained very slowly.

There is also a decrease in the amount of hemoglobin following the splenectomy. This decrease is not dependent on the loss of blood during the operation. There has also been found to be a permanent increase in the eosinophiles in all observed cases.

In a number of observations the lymph glands have been found considerably enlarged within a short time after the spleen has been removed, an enlargement which did not exist before operation.

The marrow of the bones is found to be denser and a deeper red, and complaint has occasionally been made by patients of an aching sensation in the long bones the first few days after loss of the spleen.

The condition of the blood, in most of the cases observed that long, has been found to have reached normal in six months after the operation and the restoration to health has been complete and permanent as far as observations have been made.

Theoretically, it was supposed that loss of the spleen would lower resistance to infection. Blumreich and Jacoby[6] have proved that a splenectomized animal has as much resistance to infection with bacteria or toxins as if a spleen were present. No observation has been made of any human subjects showing greater susceptibility to infection after splenectomy than before.

MORTALITY FROM SPLENECTOMY.

Having shown that the loss of the spleen is not incompatible with the continuance of life and good health it will be of interest to notice briefly the mortality from the operation. As in the development of all operations, the mortality from the earlier operations is much higher than it should be. Many spleens have been removed that no one would think of removing now. There are certain absolute contraindications to the operation, of which leukemia, *atrophic cirrhosis of the liver* and amyloid spleen are the chief. Some have considered dense adhesions to the surrounding viscera a contraindication, but the question of when such spleens are to be removed is largely a personal one and will depend on individual experience.

From all I can gather from a fairly close scrutiny of the literature I believe the present mortality of splenectomy for all appropriate conditions to be not more than from 15 to 18 per cent. Bessel-Hagen[5] even considers the mortality when there is a real reason for splenectomy to be only 12.2 per cent. When it is remembered that the mortality in these cases before 1890 was probably over 50 per cent., it shows flattering improvement. Perfection of the technic, a more judicious selection of cases and operation at a more favorable period have brought about this lower mortality and will doubtless produce still greater reduction as experience increases.

INDICATIONS FOR SPLENECTOMY.

Given then the proper indications, splenectomy is a proper operation. Its mortality is still sufficiently high to be prohibitive except for a condition incurable by any other method of treatment, or so troublesome that the patient is willing to run a considerable risk for the sake of being rid of his suffering.

In echinococcus or other cysts of the spleen, its removal is practically the only choice, except when adhesions to the abdominal wall, the diaphragm or the abdominal viscera are so great that the mortality would be prohibitive. In such cases, drainage with marsupialization of the cyst cavity has proved satisfactory, though the period of convalescence is likely to be tedious and uncertain.

Cases of abscess of the spleen must be judged on their merits. It certainly would not be good surgery to sacrifice the entire organ, if drainage would do as well. In cases of perisplenic abscess thorough drainage is in most cases the procedure to be preferred. The same may be said of a single abscess contained within the spleen, if the greater part of the splenic tissue be intact. In multiple abscesses, or when an abscess is very large and a great part of the spleen is infected or destroyed, doubtless better and safer results will be attained by entire removal of the organ.

In tuberculosis, if the organ be extensively invaded, splenectomy is the only treatment that will prove satisfactory. In those rare cases in which only the lower extremity is invaded by the tubercles resection well beyond the disease seems to be the operation of choice.

In sarcoma, an early splenectomy may prove curative, but most of the operations are likely to be so late that an early recurrence will be the rule. Exploratory operation as soon as there is a definite suspicion of sarcoma is the only treatment which gives promise of benefiting this class of patients.

TRAUMATIC RUPTURE OF THE SPLEEN.

The most constant symptoms of splenic rupture are collapse from hemorrhage, rigidity of the abdominal muscles on the left side and the occurrence of dullness in the left upper quadrant and the left flank if the hemorrhage is extreme.

Makins, in 292 cases of injury of the abdominal viscera, found rupture of the spleen in 30 per cent. of them, which proves it to be far from rare.

---

[3] Warren: Annals of Surg., May, 1901.
[4] Harris: Annals of Surg., July, 1901.
[5] Bessel-Hagen: Arch. f. klin. Chirurgie, lxii, 1900.
[6] Blumreich and Jacoby: Zeits. f. Hygiene, xxix, 1898.

A blow or wound in the splenic area followed by symptoms indicative of severe internal hemorrhage should excite a suspicion of rupture or wound of the spleen and an immediate abdominal section should be done. The course to be pursued will be determined by the conditions found. Splenectomy, suture of the rent, and tamponade each has its place, and on the judgment displayed in selecting the proper procedure much depends.

Death following rupture of the spleen is almost always due to hemorrhage, though it may be due to peritonitis, especially if it is caused by a penetrating wound. Edler[7] states that injuries of the spleen are fatal in 76.6 per cent. of the cases when no operation is done, while Lewerenz[8] claims that the mortality is 85 per cent. In 50 cases of ruptured spleen recorded by Eisendrath[9] in which laparotomy was performed, 28 patients recovered—a very forcible argument in favor of operation. One should not wait for recovery from the collapse, since the hemorrhage is continuous, and if the injury is serious the collapse will become more profound until death supervenes. It is an operation of emergency and should be done at the earliest possible moment. If the diagnosis is not absolutely convincing, it is much more dangerous to wait than to operate when the symptoms point definitely toward an injury in the left upper quadrant. If not the spleen, in all probability some other viscus needs attention.

When the abdomen has been opened and the spleen examined, a decision for or against splenectomy must depend on the extent and character of the injury and the possibility of controlling the hemorrhage by means of suture or tamponade. In general, if the injury is cortical and on the convex border well away from the arteries, not very extensive, and there is not too much pulpification of the splenic tissue, a well-placed tampon may control the hemorrhage. If it is determined to test the effect of tamponade, the operation should not be concluded until the tampon is found to be effective. If the hemorrhage is not checked by this means, the spleen should be removed at once before any more blood is lost. It is only very rarely that suture will be of benefit. The splenic tissue is so friable that the sutures cut out and the hemorrhage is likely to be made worse.

If the injury is a severe one to the lower extremity of the organ and the remainder is intact, a partial excision may be practiced, if the patient is not already too much exsanguinated.

If the injury is extensive and the hemorrhage extreme, splenectomy will be followed by the best results. Warren[3] records 34 cases of splenectomy for ruptured spleen since 1890, with a mortality of 41.2 per cent. Senn[10] says that ligation of the splenic artery will control the hemorrhage, but is followed by death due to toxemia, a poison being produced in the spleen which finds its way to the peritoneal cavity, where it is absorbed with fatal results.

Another important factor which should be taken into consideration in dealing with a ruptured spleen is that the pathologic spleen is easily injured. Lewerenz[8] found that of 131 cases of ruptured spleen, 82 occurred in previously pathologic organs. Such a spleen should be removed for slighter injuries than if the organ was previously sound.

WANDERING SPLEEN.

There are always two important questions in connection with wandering spleen: 1. Does the condition produce sufficient symptoms to demand any surgical intervention? 2. If so, shall splenopexy or splenectomy be done? In answer to the first question, no report has been made of wandering spleen, in which the symptoms have not been so distressing that operation was practically imperative.

To the second question, the answer is not so simple. The natural conclusion is that splenopexy is the safer and more conservative operation.

The facts seem to be that the idiopathic wandering spleen is of the greatest rarity and it is usually caused by hypertrophy. With this understanding of the rationale of wandering spleen, there seems the narrowest conceivable field for splenopexy.

If sufficient splenic hypertrophy is present to have stretched the ligaments and dragged the organ away from its moorings, splenopexy will not hold the heavy pathologic gland in its normal position, and if it did the primary disease would not be cured. It might be said that almost all hypertrophied spleens are wandering spleens within certain limits. The rational treatment here would be to perform splenectomy if the spleen be affected by a form of hypertrophy which is curable by this means, otherwise to let it alone.

There is one exception to the rule that a wandering spleen was a hypertrophied spleen before it began to wander. It is that rather large class of cases in which a general splanchnoptosis exists, the wandering spleen being simply an incident and certainly not to be treated by splenopexy, unless in conjunction with fixation of other viscera.

The mortality of splenectomy for wandering spleen is fortunately low. Warren[3] collects 43 splenectomies in ten years for this condition, with only three deaths, or only 7 per cent.

Wandering spleens have frequently been mistaken for ovarian cysts, uterine fibroids and movable kidneys.

MALARIAL SPLEEN.

Most writers on the surgery of the spleen previous to 1890 condemn splenectomy for malarial hypertrophy. In most cases, successful treatment of the malaria is followed by a gradual involution of the hypertrophied spleen until it reaches normal. It is not always possible, however, to attain this result, and antimalarial medication is fruitless so long as the spleen is retained, but is easily cured after removal of that organ.

Laveran states that the spleen does not protect against malaria, as has sometimes been asserted, but is a receptacle and habitat of the malarial organism. Jonnesco[11] is of the opinion that the removal of the spleen from a patient suffering from malaria cures the malaria by removing the breeding place of the organism. This seems reasonable and the results of splenectomy of the malarial spleen bear out Jonnesco's statement.

Bessel-Hagen[5] has collected records of 88 splenectomies for malarial spleen. Of this number, 24 were done prior to 1891, with 15 deaths, a mortality of 62.5 per cent.; 64 occurred between 1891 and 1900, with 15 deaths, a mortality of 23.4 per cent. A decrease in mortality from 62.5 per cent. to 23.4 per cent. in a single decade goes far to explain the change of opinion of surgeons relative to splenectomy for this condition.

Caution is needful not to subject patients to splenectomy for malarial spleen, unless the condition positively can not be relieved by medical means, but the operation should not be delayed until ascites is present.

---

[7] Edler: Arch. f. klin. Chirurgie, xxxiv.

[8] Lewerenz: Arch. f. klin. Chirurgie, lx, 1900.

[9] Eisendrath: Annals of Surg., December, 1902.

[10] Senn: The Journal A. M. A., Nov. 21, 1903.

[11] Jonnesco: Gazette des Hopitaux, lxxi, 1898.

The size of the malarial spleen does not seem to be a factor affecting the mortality, as the largest spleens have been removed with no higher mortality than those of moderate dimensions.

SPLENIC ANEMIA.

There seems to be considerable confusion in the nomenclature of the disease characterized by primary splenic hypertrophy, a decrease in the number of red blood corpuscles, a slight leucopenia, with progressive weakness, hemorrhages from the mucous membranes, vomiting, diarrhea, bronzing of the skin and death in a period varying from six months in the more rapid cases to ten or fifteen years in the slower ones. All these cases, so far as I can determine, are later complicated by hypertrophy of the liver—not always a true cirrhosis—ascites, and all the syndromes described by Banti[12] in his classical paper. Splenic anemia, primary splenomegaly, splenic pseudoleukemia and Banti's disease are doubtless one and the same, masquerading under different names.

This statement seems called for, because of a tendency on the part of some writers to refer to primary splenomegaly, splenic anemia and Banti's disease as three separate and distinct entities. Primary cirrhosis of the liver, with secondary hypertrophy of the spleen, should not be confounded with splenic anemia; neither should any confusion remain regarding splenic leukemia, which stands by itself, being characterized by a marked decrease in the reds and an immense increase of the whites. Even here it is not correct to say that if the proportion of whites to reds is 1-50 it proves the disease to be splenic leukemia and otherwise not. Osler[13] reports a case of true splenic leukemia in which for a protracted period the number of white blood cells was normal, and Murrell[14] states that often the number of leucocytes in splenic leukemia remains normal or nearly normal much of the time. The one test in these cases seems to be the presence of myelocytes, which always proves it to be splenic leukemia.

The following question is of the utmost practical importance: Is splenic anemia a primary disease of the spleen and are the blood changes and other symptoms secondary, or is the splenomegaly merely an incident to a general disease, or is it secondary to the blood changes? Osler[13] takes the ground that the enlarged spleen and the changes in the blood are both produced by the same general condition. If this were the case, it would not be logical to suppose that the removal of the spleen would bring restoration to health. The fact that this does occur has been definitely proved by hundreds of cases.

The views of Sippy[15] seem more nearly to conform to the known facts. He believes the disease of the spleen to be the primary pathologic entity and the blood changes, *et cetera*, to be the product of the splenic pathology.

Whether the anemia is produced by failure of the diseased spleen to elaborate red blood cells, assuming this to be its function, is not proved, but seems probable. Possibly chemical agents are elaborated in the pathologic spleen, which, either in the gland, or after they gain access to the circulating blood, inhibit the production of red blood corpuscles or cause their dissolution and thus induce anemia.

This might be determined by injecting the filtrate of the pulp of a hypertrophied spleen into the circulation of animals. The only experiment of this kind I know of was that of Sippy,[15] but the rabbit unfortunately died too soon to show blood changes. This opens up the possibility of some interesting research along this line, a dose being ascertained that will prove or disprove the existence of a poison inimical to the existence of red blood cells, without being fatal to the test animal.

The cause underlying the hypertrophy of the spleen is not easy to determine. Barr considers it due to a vasomotor paresis of the splanchnic area, arising from disease of the visceral sympathetic ganglia, a theory not proved, but possessing the merit of not being easily disproved.

In the absence of any rational explanation, it becomes necessary to accept the conditions without being able to explain the rationale on which they are based.

The fact that removal of the diseased spleen is usually followed by a still greater diminution of the red blood cells would argue that the pathologic organ, though not possessing its physiologic activity, is not by any means functionless, or there would be no further reduction in the number of reds after splenectomy.

The diagnosis of splenic anemia, if errors would be avoided, should be reached by the greatest care in getting all the facts and eliminating sources of errors. As has been shown by the experience of Osler[13] and Murrell,[14] a case of leukemia during one of those periods when the number of leucocytes is normal, by a careless observer, might be diagnosticated splenic anemia. The presence of myelocytes ought to prevent such an error.

The congested spleen caused by cirrhosis of the liver ought to be recognized from the history and the condition of the liver, though there is not always any material difference in the blood changes. The spleen enlarged secondarily to liver cirrhosis is not nearly so large as the spleen of primary splenomegaly. In liver cirrhosis secondary to splenic anemia, and explained by Banti as due to a toxemia, the products of which passing through the liver cause hyperplasia of the connective tissue such as is found in alcoholics, comes late in the disease, the enlargement of the spleen having existed for months or years before the hepatic condition.

In the amyloid spleen a secondary anemia is always present and the patient's general condition and history ought to prevent mistakes if one is careful.

In malarial spleen, the history is of the greatest value in avoiding diagnostic error.

In splenic anemia, the red blood corpuscles are not greatly reduced in number as a rule. Probably in the majority of cases they will range from 2,500,000 to 4,000,000 in the c. mm., though they may be reduced as low as 1,500,000 or go as high as 5,000,000.

The whites are usually somewhat less than normal. A decided leucocytosis should produce a suspicion that it is not splenic anemia, or one should look for some coincident or accidental cause for the leucocytosis.

The hemoglobin is usually very low and the color index much less than normal.

In pernicious anemia the spleen will be found only moderately enlarged, the reds lower than usually found in splenic anemia. Myelocytes are found in more than half the cases of pernicious anemia, as shown by Cabot's[16] table.

The details of arriving at a correct diagnosis are given so fully by several recent writers that nothing more need be said on this point, except to urge that when a suspicion is aroused of the existence of this disease no detail should be omitted in trying to arrive at a correct diagnosis as soon as possible. The only treatment is surgical, and the sooner the spleen is removed the better will it be for the patient. When early operation becomes the rule, before the patient becomes too greatly reduced by the ravages of the disease, the lower will be the mortality.

SUMMARY OF THE MAIN POINTS DISCUSSED.

1. The more probable function of the spleen is the manufacture of red blood corpuscles, with a strong probability of the existence of an internal secretion which is of value in maintaining the proper relative proportion of the elements of the blood.
2. Splenectomy is contraindicated in leukemia, amyloid spleen, splenic hypertrophy secondary to cirrhosis of the liver, secondary malignant disease and in the essential anemias.
3. Splenectomy is usually preferable to splenopexy in wandering spleen, which is almost always due to previous hypertrophy.
4. In abscess of the spleen, if drainage can be successfully accomplished, it is preferable to splenectomy, especially if the splenic tissue is not destroyed.
5. In cysts, benign tumors, tuberculosis and sarcoma, splenectomy is the operation of choice, unless in the three former conditions resection of the lower extremity will remove all of the disease.
6. In rupture, the organ should usually be removed. The operation should be done promptly, expeditiously, and with every expedient calculated to relieve and to prevent shock.
7. In the severe type of malarial spleen, with failure of any relief of the malaria or the extreme splenic enlargement by medical means, splenectomy will often result in cure.
8. In splenic anemia, internal medication has proven futile. The only treatment that should be considered is splenectomy, which should be done at as early a period as possible while the patient is able to withstand the operation and before incurable complications have arisen.

DISCUSSION

ON PAPERS BY DRS. BRYAN AND DAVIS.

Dr. M. L. Harris, Chicago, said that one of the most interesting and important conditions which has recently been taken from the hands of the internist and transferred to the surgeon is that of splenic anemia or so-called splenomegaly. Proper blood examinations made before and after splenectomy show that the primary condition is probably in the spleen. In all of these cases, before operation, we find that there has been a destruction of the blood cells—excessive hemolysis. He did not agree with the statement that the experiments show, or tend to show that the spleen in splenic anemia produces red blood cells. Immediately after the removal of the spleen in these cases there is a marked increase in the number of red blood cells, which would show that the red blood cells are not produced by the spleen. In two cases in which he operated for the removal of the spleen, within twenty-four hours thereafter, there was an increase in the number of red blood cells of from 25 to 40 per cent. and in one case there was an increase in the whites of 800 per cent. If these figures show anything it is that the spleen had destroyed both the red and white cells. The fact that there is always a diminished number of red blood cells, and that these cells, after the removal of the spleen, return to their normal number and remain there would indicate that in the enlarged spleen there had been excessive hemolysis. Whatever the function of the spleen may be in regard to blood formation or blood destruction, however, it is not an essential function, because patients live and maintain perfect health after the spleen has been removed. The one feature in the composition of the blood which seems to be permanent and constant after the removal of the spleen is a marked increase in the percentage of the eosinophiles. Whether the spleen has been removed experimentally or for pathologic reasons there has occurred an increase in the eosinophiles often to a remarkable extent and this increase has been permanent. It is now more than six years since Dr. Harris first removed the spleen for splenic anemia, and he has made repeated examinations of the patient's blood every three or four months since. The eosinophiles have increased to 15 per cent. and the percentage has returned to the normal and remained so. The eosinophiles are very marked and pronounced, the granules are extremely large, and they take the stain very brilliantly. This, Dr. Harris said, is the only permanent and marked change that we have been able to discover in the blood after splenectomy.

Dr. Charles A. Powers, Denver, declared that he has recently investigated the subject of cysts of the spleen and he agreed with Dr. Bryan that non-parasitic cysts of this organ are of a sero-sanguineous type and generally sub-capsular. The hemorrhages increase from time to time, and often extend over several years. Less frequently the hemorrhages are sub-peritoneal, at times they may be parenchymatous. In his case, the patient, a young man of 18, who was sent to me from Manitou, was operated on in 1895. He had an enormous left-sided abdominal tumor extending from the diaphragm to the pelvis and over to the right side. After careful examination Dr. Powers decided that it was probably a splenic cyst and operated. The wall of the cyst was densely adherent everywhere to the abdominal wall, and extirpation was impossible. Through drainage was made; the walls proved to be semi-fibrous. The cavity did not shrink, septic absorption took place from the cyst wall, and the patient died on the twelfth day. Autopsy showed the growth to be impossible of extirpation. In his search of the literature he discovered 32 of these cases, of which 28 were available for study. Of these 28 patients 3 were treated by puncture, 2 by incision and injection, 5 by extirpation of the cyst and 10 by splenectomy. Of these various procedures the only one which proved satisfactory was splenectomy: all of the ten patients so operated on recovered. Splenectomy then, is the operation of choice when it is possible.

---

[16] Cabot: Clinical Examination of the Blood.

Dr. R. E. Schlueter, St. Louis, mentioned a case of traumatic rupture of the spleen which he saw ten hours after the injury. The spleen had been completely cut in two and on opening the abdomen the two halves could be seen distinctly separated. The patient was a boy, aged 14. The abdomen was opened in the median line and by forcible traction on the belly wall the spleen was easily removed. The hemorrhage was completely arrested before the operation and the boy apparently recovered from the shock. Subsequent to the removal a slight enlargement of all the lymphatic glands of the body was noticed, and also a leucocytosis which never went above 20,000.*

Dr. A. H. Cordier, Kansas City, said that it was important to know if the disease is primary or if it is a secondary manifestation of some disease in another part of the body. He mentioned the case of a man, aged 21, who had had jaundice for 19 years. Dr. Cordier did a cholecystenterostomy at which time he noticed that the liver was very much enlarged and changed, and that the spleen also was enlarged. The patient's billiary symptoms were relieved, but owing to the changes that had taken place in the liver and spleen Dr. Cordier was afraid the results might not be permanent. A year and a half later the man returned with a typical case of splenic anemia. The liver was very much contracted. There is a class of cases occurring in drinking individuals in which there is an enlargement of the spleen, and surgeons must be very careful in their choice of operation. It is a fact that in all of these cases in which there is a contraction of the liver or the spleen there is very rarely ascites accompanying it. Enlargements of the spleen seem to be conservative in a measure, in such cases. Careful diagnosis before operation is very important in order to obtain satisfactory results.

Dr. H. G. Marxmiller, Cincinnati, said that the subject should be divided into two parts, surgical spleens and medical spleens, and it behooves surgeons to be positive in their diagnoses before endeavoring to remove spleens that are only apparently surgical. It has been his good fortune, or misfortune, to see this operation done by many good men where simple hypertrophy of the spleen has been diagnosed as some other condition, such as Banti's disease, splenic anemia, etc. If one will take a dried specimen of the blood and properly stain it the condition of the blood can readily be brought out, and the presence or absence of leucocytes or myelocytes or eosinophiles should caution the surgeon as to the removal of the spleen. Perhaps in a few instances the spleen can be removed with good results. Splenectomy for leukemia and allied conditions has given a mortality of almost 100 per cent. and we should not be quite so bold in the removal of these spleens. Senn, Dock and others have reported cases of splenic anemia that sometimes follow protracted cases of typhoid and malaria, in which complete recovery has followed the use of the *x*-ray. Dr. Maxmiller has had under observation for several years a case of chronic myelogenous leukemia. When he first saw the case, the patient had all the symptoms of splenic enlargement. The spleen reached to the brim of the pelvis and increased the abdominal circumference by eight or nine inches. Although operation had been recommended it would have been folly to have removed this spleen. The presence of the subcutaneous extravasation of blood and the approach of the fatal termination was almost apparent. This case was controlled by the internal medication of adrenalin chlorid, 1-1000 in thirty minim doses, four times daily, and the application of *x*-ray directed to the splenic substance. The spleen has been reduced almost to its normal size and the patient has continued up to the present time in good health. Cases have been reported in which even in simple anemia, with hypertrophied spleen, splenectomy has been done, and following this death has occurred from hemorrhage, patients succumbing within a period of from three to seven days following operation. A thorough diagnosis must first be made and then an endeavor to relieve these conditions by other methods before attempting splenectomy.

Dr. McDaniels, San Antonio, reported the case of a woman from whom he removed the spleen six years ago and who has since borne children and remained well.

Dr. W. Jepson, Sioux City, Iowa, said that in considering affections of the spleen from the standpoint of the necessity of removal of that organ, he thinks these can be classified under several headings. First, those affections which are primarily of this organ, as for example; sarcoma, carcinoma, various forms of cysts, tuberculosis and miliary abscesses. Under this heading may also be classed injuries and displacements of the spleen. Second, affections of the spleen which are secondary to pathologic processes located elsewhere in the economy, as for example: the splenomegalies of malaria, leukemia, splenic leukemia, etc. The first class of cases cited demand splenectomy because the pathologic process can not be otherwise satisfactorily dealt with. In the second class of cases, in which the splenomegaly is secondary to a primary process located elsewhere, splenectomy can hardly, in his opinion, be justified, except on the ground that the spleen is of such a size as seriously to impair the function of other intra-abdominal viscera. As an ovarian cyst or other intra-abdominal tumor, by reason of its size, may jeopardize the life of the patient, so in a similar manner may the enlarged spleen threaten health and life and when such is the case it would constitute a just reason for its removal. As our knowledge of the spleen is not definite, it would seem that care should be exercised against sacrificing this organ unless the indications for so doing are very clear, even though a large list of splenectomies show apparently perfect health after. Dr. Jepson said that in one splenectomy the blood changes consisted of a fall of red corpuscles from above 5,000,000 before the operation to 3,300,000 the day following the operation and it was only after three weeks that the number reached approximately 4,500,000. During this time the whites increased from 6,000 to 27,000. In another case of splenectomy, in a case of Banti's disease, the blood changes were somewhat similar as regards the red corpuscles but he could not recall with certainty the exact changes. He had interpreted the diminished number of red corpuscles as possibly being due to blood loss which, however, was slight in each case.

Dr. Jefferson D. Griffith, Kansas City, stated that he has operated in several of these. One operation was for hernia of the spleen in a child six years old. The spleen had escaped, following a severe attack of whooping cough, and when the child was brought to him he did not know what was the matter. There apparently had been very few symptoms other than fretfulness. On cutting down he encountered a large body which proved to be the spleen. It was lying well down and was not strangulated. After ligating the vessels he took it away; the child made an uneventful recovery. The parents have since told him that the child's whole disposition has changed. The case occurred ten years ago and in the meantime the child's disposition and temperament, which before the operation were phlegmatic, have now grown to be rather nervous and vicious.

Dr. W. A. Bryan said that he has appended to his paper a list of the cases that he has been able to collect of non-parasitic cysts. There was one of dermoid, 12 of cysts classified as simple or serous, 24 of cysts classified as hematic or blood, and 4 that were not definitely classified. There are 41 cases of non-parasitic cysts of the spleen so far recorded, but only 12 have been classified as simple. If these 12 could be analyzed it would be found that many of them should be classified with the blood cysts. Simple serous cysts are exceedingly rare. The danger of splenectomy is a great deal larger in those cases in which the spleen is functionating than it is when the function has disappeared. In the case reported by Dr. Bryan the cyst and spleen together weighed two and a half pounds, but there was not more than one and a half ounces of real spleen tissue.

---

* A report of this case was published in the Journal of the Missouri Medical Association, July, 1905.

Dr. B. B. Davis stated that he has looked over the literature on removal of the spleen and in practically all the cases of splenectomy done on animals for experimental purposes and cases of splenectomy done for rupture, the operation has been universally followed by a decrease in the reds. In the few cases in which splenectomy has been followed by an increase in the reds there has been some reason for it. In a case reported by Harris some years ago the condition had been present for years. In such cases Dr. Davis believes that the vicarious function carried on by the bone marrow becomes established and this affects the blood formation. He said that if Dr. Harris will look up the literature he will find that it will bear out the statement that the removal of the spleen does reduce the number of red blood cells. The very fact that in these cases, in which there has been a careful study beforehand, the removal of the spleen has been followed by restoration to health shows that the splenomegaly is the primary lesion. It will not be possible to put this class of cases along with the case of which Dr. Jepson spoke. In primary splenomegaly there is a secondary cirrhosis of the liver, and ascites. Operation should be done in these cases before these complications arise, as the patients are very likely not to be helped by the operation.

ACID INTOXICATION, AND LATE POISONOUS EFFECTS OF ANESTHETICS.

HEPATIC TOXEMIA. ACUTE FATTY DEGENERATION OF THE LIVER FOLLOWING CHLOROFORM AND ETHER ANESTHESIA.*

ARTHUR DEAN BEVAN, M.D.,
AND
HENRY BAIRD FAVILL, M.D.,
CHICAGO.

In January, 1905, there occurred in our practice a case of gangrenous ovarian cyst with twisted pedicle. The patient was operated on and the case terminated fatally four days and a half later. The clinical picture was a very unusual one. Although we were aided in the conduct of the case by four consultants, a gynecologist, an internist, a neurologist, and a pathologist of more than ordinary ability, no definite diagnosis of the cause of the singular symptoms could be made. The parents of the child, fortunately, were intelligent and considerate and, realizing the importance to humanity and to science of ascertaining the exact cause of death, as the first step to the prevention of a similar result in other cases, permitted a postmortem examination. This was made with the greatest thoroughness, gross, microscopic and bacteriologic, and yet even then the cause of death was obscure and remained so until a careful review of the literature enabled us to collect twenty-nine more or less scattered cases, either identical or very similar to our own, in the light of which we believe the diagnosis becomes clear. We have found also certain comparatively recent experimental work reported, which assists materially in the understanding of the case.

DR. FAVILL'S REPORT OF CASE.

We shall cite first the outline of our experience, which it seems worth while to report, first, because of its essential importance as a positive clinical picture; second, because of its value with respect to negative demonstrations.

Patient.—A girl, aged 12½ years, with the stature of a woman and the mental development of a girl of 16 or 18. Not at all a "freak," but simply a noticeably handsome, well-developed and intelligent girl. She menstruated at the age of 11½ and was reasonably regular thereafter.

History.—Her history as to illness is negative. At 3 she had an acute otitis media which was treated by puncture, under chloroform, and recovered promptly and permanently; since that time no illness of any consequence, though she was of a lithemic type.

January 17: She came home from skating, complaining of great pain in the lower abdomen. Her menstruation being due, though it was habitually painless, her pain was ascribed to that fact. The pain was very severe. When seen two hours later it was somewhat less, but still severe. Temperature, 98.4; pulse, 72; general abdominal tenderness, but absolutely no local increase. The appendix was excluded and the conclusion as to premenstrual pain adopted. Some whiskey was given her, which she vomited.

A nurse was called; the child was covered with a flaxseed poultice on the lower abdomen, given small doses of phenacetin at intervals and saline cathartics.

January 18: In the morning her temperature was normal, but she was still in some pain. Temperature in the evening was 99. She had a comfortable day and began to menstruate at 11 p. m.

January 19: Thursday was an uneventful day; very little pain, no abdominal distension and very little tenderness; the bowels moved twice slightly; temperature at 5 p. m. was 99. She vomited some orange juice at noon; she was cheerful and feeling well, however.

January 20: Friday she was still in pain; temperature, 100.5. Inasmuch as the menstrual conditions did not seem to justify any increase of symptoms, suspicion was aroused; a blood count showed 11,600 leucocytes. Dr. Bevan was called in consultation. Temperature gradually rose and slight tenderness developed in the neighborhood of the appendix. At 2 o'clock the temperature was 102.2, leucocytes 14,000. Free bowel movement. At 9 p. m. the temperature was 102.6, pulse 108, leucocytes 16,500. Dr. Webster was called in consultation.

A diagnosis of appendicitis was fully agreed on and an operation was performed about midnight.

Previous to the operation a thorough pelvic examination was made bi-manually by rectum, but no palpable abnormality was found.

Operation.—The operation was performed under chloroform, and it is noteworthy that it took a long time and an unusually large amount of chloroform to establish anesthesia. The exact amount of chloroform, however, was not noted at the time, but it is clear that in both respects the anesthesia was noticeable.

Because of some rather definite sense of resistance under the right rectus muscle, just above the pubes, the incision was made through the right rectus. The peritoneal cavity was opened and the appendix was found injected and buried in lymph directly under the incision. It was removed and the stump invaginated in the ordinary way. On separating the coils of intestines which surrounded the appendix, a black mass was seen. At first glance this was thought to be a gangrenous bowel, but on separating the intestines a gangrenous ovarian cyst and tube of the left side were brought into view. The intestines in contact with the mass were covered with a thin layer of lymph. There was no pus. The pedicle was ligated proximally to the point of torsion and the dead mass removed; the abdomen was closed without drainage. No time was lost in any way, and although the exact time was not noted, the operation was a rather short one.

Postoperative History.—From the time of operation till death, the dressings were not removed from the wound. The abdomen was flat, soft and painless, and there were absolutely no evidences of peritonitis.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

The patient was returned to bed in excellent condition; temperature 101.6, pulse 102, and thoroughly conscious at 1:45 a. m. The succeeding hours were unusually comfortable. The temperature steadily fell until Saturday at 11 a. m., when it was 99.8; pulse 86; respiration 23, and leucocytes 12,000. The patient had a very comfortable day; temperature 101.2 at 4 p. m.; she vomited a trifle at 7 p. m., and flatus was expelled freely.

January 22: Sunday, at 8 a. m., the temperature was 98.6; pulse 100. She slept more or less during the night, vomited a little and passed several slight stools. She complained of feeling hungry. She continued in this comfortable way all day Sunday. At 7 p. m. temperature was 99.2, pulse having risen to 112, and the mother noticed that the patient was not quite natural in her remarks. The attention of the physicians was called to this point, but the incident was so slight as to seem unimportant to them. At 11 p. m. the physicians were again called. The child was talking incoherently and exhibiting evidences of very great fright.

The picture of this mental condition is so unusual and from comparison with the experiences of others so typical that we venture to dilate on it. First, its appearance almost out of a clear sky. The child had been phenomenally favorable in her progress until forty-four hours after the operation. Second, the element of fright as the initial manifestation. Third, the rapid lapse into incoherence and unremitting delirium. Her first noticeable departure from the normal was at 8 p. m. on Sunday, and at 11 p. m. she gave the last obvious recognition of anybody. From that time on it was a series of alternations between sleep and delirium, more or less talkative, with a curious shrieking outcry. The delirium was controllable to a certain extent by small amounts of morphin hypodermatically, but except for that nothing seemed to affect her condition.

Consultation with Dr. Patrick.—Of course, the question of septic meningitis arose immediately. At noon on Monday, January 23, Dr. Patrick was invited into consultation. At that time there were present the following significant signs: Considerable muscular rigidity, exaggerated tendon reflexes, particularly patellar, ankle clonus and a perfectly marked Babinsky's reaction. Nevertheless, the consultation did not result in a clear diagnosis of meningitis.

Dr. Hugh T. Patrick's Statement.—From a neurologic standpoint the case presented several interesting and very instructive features.

First, the very early appearance of delirium without other symptoms of profound intoxication, and with no signs of organic disease. The rather quiet delirium of the confusional sort, with no definite tendency to depression or exaltation; no definite type of delusion or hallucination enabled one to exclude all of the ordinary psychoses. The varying indifference to surroundings, the occurrence of relatively lucid moments, and the well-marked impairment of recognition of time, location and personality placed the case in the class of toxic psychosis or delirium, as delirium tremens, Korsakoff's psychosis. Absence of all signs of gross organic disease allowed the provisional exclusion of meningitis, or brain abscess, consequently, a diagnosis of toxic delirium was made; source of toxemia undetermined.

Second, the appearance of ankle clonus and Babinski's sign or "extensor response" with corroborative evidence of gross brain or cord disease, was confusing. As is well known, Babinski's (or Collier's) sign indicates a lesion of the pyramidal tract. It is not to be elicited in every case of disease of this tract, but its presence in typical form is almost indubitable evidence of such disease. It is known, too, that this sign may be found in acute lesions, even a very few minutes after cerebral thrombosis or hemorrhage. Combined with delirium, another cerebral symptom, it would be taken to indicate a lesion or lesions of the cortex or subcortical tissue. Ankle clonus is also indicative of a lesion of the pyramidal tract, but is exceedingly rare in acute diseases, such as hemorrhage, thrombosis, inflammation. Occasionally it is found in rigid or hypertonic states due to compression of the motor cortex, as in meningeal hemorrhage. I do not recall having seen it well defined in acute meningitis, though I suppose it might be possible. So far as I know, neither Babinski's sign nor ankle clonus has been reported as due to intoxication without gross, or well advanced, microscopic disease. The eye grounds were negative.

Consultation with Dr. Billings.—Monday afternoon Dr. Billings was invited into consultation. The conditions were about the same, except that the pulse was steadily going up, and the temperature slightly, being 101.6, the pulse 130 and the respirations 21. There was also more or less suspicion of endocarditis and pericarditis, and it was suspected that the sepsis had invaded the cardiac structures.

Dr. Billings' Statement.—The symptoms indicated profound intoxication. There was coma, with marked congestion of the skin and of the mucous membranes, with moderate cyanosis and rapid heart action, irregular respirations, relaxed sphincter ani and retention of urine. At regular intervals a period of excitement, practically a convulsion, would occur, lasting one minute or perhaps longer. This was manifested by a deeper redness of the skin and mucous membranes, a tonic contraction of all the voluntary muscles, by gradually increasing respiration, both in number and depth of chest movements, by stertor, by a tumultuous beating of the heart, by dilatation of the pupils and, at times by escape of the fluid contents of the rectum. The tonic contractions of the muscles occurred with the extremities extended and the head drawn slightly backward, with the neck muscles rigid. In the early stages the forearms were alternately flexed and extended with the hands closed. The stage of excitement was followed by a longer period of quiet. During this time the respirations were quiet, slow, shallow and almost imperceptible. The heart beat rapidly, but not as forcibly as during the stage of excitement. The muscles were relaxed, the pupils equal and moderately wide. Physical examination of the chest showed no abnormal lung findings. The heart showed evidence of dilatation. The apex beat was displaced to the left and was diffuse. The left border dullness was one inch to the left of the nipple line, the base to the second rib, and the right border one inch to the right of the right sternal border. During the early stage no murmurs were heard. Soon a loud apical and basic systolic murmur could be heard during the period of excitement. During the last day systolic murmurs could be heard at all times and during the convulsive period, with the tumultuous beating of the heart loud churning murmurs were heard. During the last day a distinct to-and-fro friction could be plainly heard over the base of the heart. There can be no doubt that acute dilatation of the heart occurred. Postmortem contraction and rigidity of the heart muscle of course does not negative this statement.

Termination of Case.—The progress on the following day, Tuesday, was uneventful, the pulse remaining high much of the time, the temperature varying between 99.4 and 101.8, respirations between 22 and 28. Cheyne-Stokes respiration was present. The conditions continued without material change until Wednesday morning, when the temperature gradually began to rise; the pulse became very irregular and rapid, and finally death ensued at 2 o'clock, 110 hours after operation.

AUTOPSY.

The postmortem examination made by Dr. Hektoen at the expiration of seven hours revealed the following facts:

Anatomic Diagnosis.—Recent laparotomy; wound removal of vermiform appendix and of left ovary and tube; local purulo-fibrinous peritonitis about field of operation; retrocecal ecchymosis; thrombus of left ovarian vein; fatty changes in the liver; swollen spleen; chronic nephritis (minimum degree), with acute degeneration; multiple ecchymoses; edema and congestion of lungs; acute bronchitis; chronic fibrous peritonitis about right tube and ovary. Menstruation.

Macroscopic Examination.—The body is that of a well-developed, well-nourished girl. It is still warm and rigor-mortis is beginning. There is a recent sutured incision with normal margins to the right of the median line, beginning on a level with the navel and running down about 10 centimeters.

The general abdominal cavity is empty; in the pelvic portions there is some turbid blood; the omentum, ileum, cecum and sigmoid are matted together by a fibrinous exudate in the pelvis and behind the incision, the upper inner part of which is gaping, the margins here appearing somewhat soft and yellowish. The vermiform appendix is absent, the stump closed and water tight, with yellowish margins. The left tube and ovary are absent, the stump being sutured, the margins soft and yellowish. The left ovarian vein is closed by a red, quite firm, adherent clot. The right tube and ovary are embedded in firm, fibrous adhesions and flattened out beyond recognition against the bladder and wall of the pelvis. There is a large area behind the cecum sparsely infiltrated with blood.

The pleural and pericardial cavities are empty and smoothly lined. The lungs are somewhat congested and edematous, especially posteriorly. There is no bronchitis. The heart contains some blood; the endocardium is smooth; the muscle is firm; the intima of the aorta, vena cava and iliacs is smooth.

The spleen is large and quite firm; the Malpighian bodies are large and distinct. The liver is universally yellow, with no lobular centers; it is quite firm and larger than normal. The stomach is normal, with some softenings of the mucosa and some ecchymoses. The kidneys are large and firm, the capsules adherent in a few small places, the cortex thicker than normal, the markings not distinct; ecchymoses are present in the pelvis. The urinary bladder is normal; there are some ecchymoses in the mucosa.

The brain and its membranes are normal.

Microscopic Examination.—Kidneys: There are some chronic fibrous changes as shown by partial or complete obliteration of an occasional glomerulus and some, though slight, increased thickness of the capsules of many glomeruli. The most striking change is the presence of large amounts of granular material (coagulated serum) in the cavities of the glomeruli visibly compressing many of the tufts. The cells lining Bowman's capsules are not much changed. The convoluted tubules are filled with a similar granular material, while the epithelial cells are well preserved. There is marked congestion of the vessels.

Liver: There is an advanced fatty change at the peripheries of the lobules. The central portions are congested, the columnar arrangement of the liver cells is thrown into disorder.

Spleen: This organ shows great congestion; the follicles are cellular.

Lungs: There is great congestion in the posterior parts of the lower lobes; here the cells contain many blood corpuscles, some being crowded. Some of the bronchioles are filled with leucocytic exudate.

Heart: The heart shows no changes.

Internal Margins of Abdominal Incision: There is marked congestion and leucocytic infiltration, but no demonstrable bacteria.

Left Ovarian Vein: A recent red thrombus is present. There are no bacterial masses.

Bacteriologic Examination.—Two flasks of broth and two of ascites broth inoculated with 1.5 c.c. of blood withdrawn from the right elbow twenty hours before death remained sterile.

Cultures from the heart's blood, the liver and the spleen made at the autopsy remained sterile. Cultures from the peritoneal exudate gave *Streptococcus* and *Staphylococcus pyogenes aureus* in agar plates, in milk tubes and on blood-agar slants. The smears from the exudate showed only a few cocci.

Remarks.—It is to be noted that the local peritonitis was limited to the area from which the appendix and gangrenous cyst had been removed and that it was less marked at the time of postmortem than at the time of operation. Sections of the appendix and cyst showed streptococci and staphylococci.

Blood: The blood conditions during the postoperative period were as follows: The first day, Saturday, leucocytes 12,800, the second day, Sunday, not noted. The third day, Monday, 15,200, the fourth day, Tuesday, 14,800. Evidently not especially significant.

Urine: The urinary conditions were significant. The urine was examined before the operation and found to be negative. Following this examination it was examined frequently, and found on January 23, which was Monday, to be a highly concentrated urine, with an acidity of 11.6, containing diacetic acid, a trace of acetone and one and one-fourth (1.25) grams per liter of albumin, and a number of hyaline, granular and waxy casts. A subsequent examination on the same day showed less albumin, no acetone and less diacetic acid. The following day, Tuesday, there was still albumin, diacetic acid and a little blood. Later in the same day it was still highly acid, with less albumin, more diacetic acid and a great deal of blood. The same day, at 3:30 p. m., diacetic acid was absent; the other conditions were unchanged. Later, Tuesday, the conditions were the same, but with no diacetic acid. The next day, Wednesday, the urinary conditions were much the same; there was less blood and albumin and no diacetic acid. At 9 a. m., on Wednesday, the day of death, there was the same condition of nephritis, with no diacetic acid, but a great deal of blood.

It is to be noted that her breath on Tuesday and Wednesday had a sweetish, acetone odor.

Opinions of Physicians in the Case.—The opinions during the progress of this case were various. First, the assumption was that it was septic. Certain of the consultants had a reservation, feeling that it was some sort of autotoxic condition. A blood examination made by Dr. Hektoen during life was entirely negative.

The commentary of Dr. Patrick on the nervous manifestations particularly bearing on the question of meningitis is herewith included.

The deduction of Dr. Hektoen from his postmortem investigations is also included.

The deceptive signs indicating cardiac involvement with absolutely negative findings at autopsy are interesting.

The true nature of this experience has only unfolded itself gradually under the enlightening influence of the negative findings and an exhaustive study of the literature.

REVIEW OF LITERATURE.

There have appeared in the literature from time to time since 1846 and 1847—the years marking the introduction of anesthetics—the reports of a number of cases resulting fatally after operations, in which anesthetics were employed. These cases presented unusual symptoms, and postmortem findings which could not be attributed to the more common causes of death after operation, such as shock, hemorrhage, sepsis, pneumonia, uremia, etc.

A certain considerable number of these obscure cases, because of the identity of symptoms and postmortem findings, evidently belong to the same group and are certainly the result of the same obscure causes.

The cases to which I refer have been reported under several headings. Guthrie[1] reports nine fatal cases under the title, "Some Fatal After Effects of Chloroform on Children." Brewer[2] reports a similar case as "Fatal Acetonemia Following an Operation for Acute Appendicitis." Kelly reports these cases under the title of "Acid Intoxication; Its Significance in Surgical Conditions."

Brackett, Stone and Low[3] report this group under the title of "Aciduria (Acetonuria), Associated With Sudden Death After Anesthesia." Other authors have reported these cases as deaths due to acute yellow atrophy of the liver. Cohn[4] reports a case under title of "A Case of Protracted Effect of Chloroform, with Fatal Termination."

Stocker[5] reports a case identical with our own as one of acute yellow atrophy of the liver after the twisting of the pedicle of an ovarian cyst. Without doubt many of those deaths have not been correctly interpreted, and have been regarded as deaths due to late shock, fat embolism, sepsis, meningitis, uremia, etc.

Within the last year the evidence on this subject has accumulated rapidly, and it would seem that the time has arrived when the large number of clinical reports and the experimental laboratory findings have thrown enough light on this obscure subject to warrant an attempt to analyze the evidence at hand and to determine the essential cause of death, to describe the usual symptom-complex and to determine the postmortem findings of this heretofore little understood pathologic condition. Most of us, I believe, even those of us who have had a comparatively wide experience in surgery, have felt that after the giving of an anesthetic, if the patient recovered from its immediate effects, that there were no further dangers from the anesthetic, except such well-known dangers as pneumonia and nephritis, conditions which could be recognized readily by proper means of diagnosis. We have thought little about, and paid little attention to the possibility of late obscure poisonous effects of chloroform and ether which were difficult to recognize, and frequently fatal in termination. Yet as early as 1850, Casper[6] recognized the late poisonous effects of chloroform, and in 1862 said:

> It can no longer be doubted that there is such a thing as chronic poisoning by chloroform—that is, that the drug when it does kill does not always kill instantaneously, but that hours, days or even weeks may elapse during which the person anesthetized remains continuously under the influence of the poison to which he at length succumbs.

Experimentally, the truth of Casper's statement has been proved by a number of investigators. Nothnagel,[7] in 1866, proved that chloroform produced a fatty degeneration of the liver and heart muscle, when injected subcutaneously or into the stomach.

Ungar,[8] in 1887, showed that chloroform inhaled by animals as it is used as an anesthetic produces a fatty degeneration of various organs, especially of the liver, very similar to the fatty degeneration of the liver in phosphorus poisoning.

Strassmann,[9] in 1889, showed that animals weakened by loss of blood and then chloroformed showed a much more extensive fatty degeneration than those not so weakened.

In 1890, Thiem and Fischer[10] reported the first case in clinical work of a man who died four days after chloroform anesthesia, in whom the postmortem showed fatty degeneration of the liver.

Bastianelli,[11] in 1891, reported three deaths occurring in from three to ten days after chloroform narcosis, without any other apparent cause. These patients presented as symptoms: Vomiting, icterus, delirium and coma, and at postmortem in one case extensive fatty degeneration of the liver was found.

Fraenkel,[12] in 1892, reported cases with careful microscopic and macroscopic studies of the changes of the internal organs after protracted chloroform narcosis. In each case, he noted extensive changes in the liver cells, but did not attribute the death to these, as there [illegible] initely pointing to the liver. after [illegible]

Luther[13] in 1893 noted the occurrence of icterus.

Bandler,[14] in 1896, after a review of the literature up to that time, and a careful study of a case in Wölfler's clinic, came to the conclusion that chloroform under certain conditions can produce serious effects a long time after its inhalation. The effects on the heart and kidneys are well known and fairly generally recognized. The changes produced in the liver are little known and understood. He believes, however, that the liver is affected by chloroform used as an anesthetic in varying degrees from a scarcely perceptible lesion to an almost total destruction of the organ.

Bandler cites the fact that Nachod found bile in the urine after chloroform anesthesia, without any apparent icterus. He himself had found it in ten cases in which there was scarcely any evidence of icterus in the sclera. He believes that the evidence of the destructive effect of the chloroform on the liver cells is found in the cases of chloroform icterus, which are marked, but which disappear in a few days, with the recovery of the patient. He believes that the extreme degree of chloroform poisoning is found in the fatal cases of acute yellow atrophy of the liver which follow its use, an example of which he reports.

In the light of his investigation, Bandler believes that just as the heart and kidneys are carefully examined before the giving of an anesthetic, and their condition recognized as important in the choice of the anesthetic agent, so the condition of the liver, if possible, should be determined before the anesthetic, and when any liver lesion is found, chloroform should not be employed, but ether should be the anesthetic of choice, because, as he showed by animal experiments, ether does not produce the destructive effects on the liver cells found so constantly after chloroform anesthesia.

Offergeld,[15] in 1905, in an experimental study of the poisonous effects of chloroform on the kidneys, presents some most interesting results.

> Animals chloroformed for a long time (up to two hours), after recovery from the immediate effects of the anesthetic, seemed perfectly well, played about and ate. On the second day they were less lively, and not so hungry as usual. Later, they would lie down in the corner, and could be made to move about only with difficulty, and then they would at once lie down again; usually at the end of from 48 to 60 hours they were dead. A postmortem examination showed that in these animals—rabbits, guinea-pigs—after a single narcosis parenchymatous degenerations occur in the heart, liver and kidneys, which produce death after a short time, even though the animal has apparently stood the anesthetic well.
>
> In a second series of experiments it was shown (*a*) that fatty degeneration of the kidney did not occur in the kidney which had its arterial supply cut off by ligation of the renal artery after forty minutes' anesthesia; (*b*) that fatty degeneration of the kidney occurred in a most pronounced type after ligation of the renal vein, after thirty minutes' anesthesia; (*c*) that fatty degeneration occurred more rapidly after ligation of the ureter, even after twenty-five minutes' anesthesia.
>
> In a third series of experiments, in which an artificial nephritis had been produced, extensive injury was produced, even by fifteen-minute anesthesia.

In a fourth series the kidneys were injured by mineral acid and mercury, and then short—ten, fifteen and twenty-minute—anesthesias were found to be followed by death and the usual fatty degenerations.

In a fifth series the kidneys were injured by pus germs, and it was shown that a nephritis greatly favored fatty degeneration after chloroform narcosis.

In another group diphtheria toxins were injected into the animals, with the result that it was shown that the kidney inflammation produced by these poisons furnished an excellent soil for the development of fatty degeneration after chloroform narcosis.

In a sixth series, in which pregnant animals were employed, it was found that pregnancy in itself did not favor fatty degenerations, but that pregnancy complicated with kidney lesions did.

In a seventh series animals which had recovered from a previous short anesthesia were again chloroformed, and it was found that the fatty degeneration produced by the first anesthesia favored greatly the intense injury of the kidneys from a second anesthesia.

In an eighth series an effort was made to ascertain the effect of diet, and the conclusion was reached that after chloroform narcosis the urea in the presence of a nephritis is irregular in amount.

In a ninth series, after twenty-minute anesthesias on a number of animals on the same day, one was killed each day, and it was found that regeneration is possible.

In a tenth series the conclusion was reached that after chloroform narcosis fat disappears in the tissues and accumulates in the liver, so that the percentage of fat increases in the liver, while it decreases in the other organs.

In an eleventh series the conclusion is reached that the anesthesia produced by chloroform and oxygen does produce degenerative changes in the kidney, but only to a limited degree, and in a few days complete recovery follows.

Offergeld experimented a little with ether, but found that most of his animals died, even after from thirty to sixty-minute anesthesias, of pneumonia.

Offergeld believes that there is a certain idiosyncrasy in regard to chloroform and that some individuals can take amounts without injury which would produce extensive degenerations in another. He points out the importance of the knowledge that anemic and cachectic conditions of the patient favor the poisonous action of chloroform, and also the dangers of repeated anesthesias following closely one after the other.

Offergeld found constantly in his experiments that the most marked change at death was found in the liver. He came to the conclusion, however, that death is due to the production of a nephrolysin resulting from the effect of the chloroform on the kidney cells.

Offergeld believes that the prevention of this ill effect of chloroform may be accomplished by the use of a mixture of chloroform and oxygen.

Under the title of fat metamorphosis in the internal vital organs after simple and mixed narcosis, Benno Müller[16] this year reviews much the same ground. Müller made fifty animal experiments, with the usual anesthetics. His conclusions are as follows:

1. Anesthesia with chloroform, chloral hydrate, bromethyl and chlorethyl, ether and mixtures of these always produce changes in the internal organs, which appear as beginning fatty changes.

2. Fatty changes occur also in the epithelium of the respiratory tract.

3. The fatty changes in degree and extent depend on the time and number of the anesthesias.

4. The power of the various *anesthetics* to produce fatty changes is in direct proportion to their anesthetic power.

5. These fatty changes usually disappear shortly after the anesthesia. If a second anesthetic, however, is given before the fatty changes of the first have been recovered from, the effects of the second are enhanced and the cells become necrotic.

It makes little difference when the second anesthetic is given, the fatty changes after the second are twice as severe as from the first.

6. The anesthetic continues to produce fatty changes as long as it is present in the blood. The fatty changes can not go on to restoration to normal until the blood has freed itself from the last vestige of the drug.

7. It is hazardous to give a second anesthetic within three days after the first, and the anesthesia should be as short as possible.

8. Pneumonia occurs frequently after ether and ether mixtures; because of a possible pneumonia after a first ether anesthesia, one should choose chloroform for a second.

9. Each anesthetic produces after long use an increase in the mucous secretion. One finds in the lung after each anesthesia small areas filled with mucus (not infected pneumonic areas), which very soon disappear, but which are greatly increased by a second anesthesia inside of from twenty-four to forty-eight hours.

10. Chloral hydrate forms chloroform in the system.

11. The mixed anesthesias have no property of prevention of fatty changes in the internal organs.

12. Every anesthetic produces fatty changes in the vessel walls of the brain, and in the ganglion cells up to a certain stage and in the other internal organs.

THE CLINICAL SIDE.

With the assistance of Dr. Dean D. Lewis, we have collected from the literature 27 fatal cases after anesthesia, making with our own 28, which from symptoms and postmortem findings belong, we believe, to the same group. In two cases reported in the literature the patient recovered:

Bastianelli reported 3 cases; Bandler, 1 case; Ballin, 1 case; Brackett, Stone and Low, 3 cases; Brewer. 1 case; Cohn, 1 case; Erlach, 1 case; Guthrie, 14 cases; Kelly, 1 case; Marthen, 1 case; Stocker, 1 case; Mintz, 1 case; Bevan and Favill, 1 case. Total, 30. Chloroform was employed in 23 cases; ether in 4 cases; Billroth mixture in 1 case; not stated, 2 cases. Total 30.

We summarize below the essential facts in each case:

Bastianelli,[11] in 1890, reports 3 cases in which death occurred on from the third to the tenth day following the use of chloroform. In two of the patients vomiting was frequent and profuse. The patients were icteric and restless. Just before death they became comatose. Autopsy revealed a fatty degeneration of the heart, kidneys and liver. The fatty changes in the latter organ were most marked in the center of the lobule and resembled closely those found in other poisoning, especially phosphorus.

The original article was not accessible, and no statement can be made concerning the age, sex and predisposing causes.

These are probably the first cases reported and published of true late chloroform poisoning. Thiem and Fischer published somewhat earlier the autopsy findings in a patient dying four days after chloroform, but this case must be accepted with some reserve, as it is regarded by Fraenkel as delirium tremens.

Guthrie, in 1894, reports the clinical histories of ten patients; nine died and one recovered. The autopsy findings in eight fatal cases are given:

Case 1.—Male child, aged 3, under the care of Mr. Watson Cheyne, was operated on in 1887 for vesical calculus. There were no predisposing causes. Chloroform was used as an anesthetic. Two and one-half hours after the operation the child was restless. Vomiting was noted at this time. Eight hours after operation the child repeatedly uttered piercing shrieks, tossed about in bed, and was sweating profusely and was cold.

---

[16] Muller, B.: "Ueber Fettmetamorphose in den inneren farenchym lebens wichtige Organen nach Einfachen u. Much narkosen." Archiv. f. klin. Chir., 1905, No. lxxv, p. 876.

Death occurred suddenly ten hours after operation. Screaming continued until a few hours before death.

Autopsy.—Lungs and liver normal; spleen slightly enlarged; kidneys, both in early stages of granulation, congested; capsule somewhat adherent. Brain congested, but no evidence of inflammatory changes in meninges.

Case 2.—Female child, aged 7, under the care of Mr. Stanley Boyd. Anemia possible predisposing cause. An excision of the knee joint was done under chloroform anesthesia. The carbolic acid spray was used. Patient was collapsed after the operation. Four and one-half hours after the operation the child began to vomit incessantly. Shrill screams were uttered. the restlessness finally passed into coma, and death resulted twelve hours after the operation.

Autopsy.—The pelves of both kidneys contained pus. All other organs appeared normal.

Case 3.—Female child, aged 4, under the care of Mr. Watson Cheyne, was operated on for double genu valgum. Chloroform was used as an anesthetic. The operation lasted about one hour. No predisposing causes. Vomiting commenced about five hours after operation. The child became delirious; the delirium alternating with apathy. Child screamed constantly. Temperature rose to 102, just before death, which occurred twenty-seven hours after operation.

Autopsy.—The liver was found somewhat pale and greasy. Kidneys and spleen were normal. The heart muscle was pale, but not fatty. There was considerable venous congestion in the brain; otherwise normal.

Case 4.—Male child, aged 1 year 4 months. Service of Mr. Watson Cheyne. Carbolic-acid intoxication may have been predisposing cause. Operation was done for congenital hydrocele under chloroform anesthesia. Lengthy operation. Excessive vomiting was noted soon after operation. Death occurred twenty-four hours after completion of operation.

Autopsy.—Liver large, firm and pale. Microscopically, fatty infiltration.

Case 5.—Male child, aged 4. Service of Mr. Stanley Boyd. Operation for correction of double talipes equino varus, resulting from infantile paralysis. Chloroform anesthesia. Symptoms began thirteen hours after operation. Vomiting was frequent and profuse. Child soon became unconscious. Just before death temperature rose to 101. Death occurred thirty hours after operation.

Autopsy.—Liver small, weighing 14½ ounces; microscopically, two-thirds of the external portion of the lobule was fatty. There was intense fatty infiltration, perhaps unaccompanied by fatty degeneration.

Case 6.—Female child, aged 8. Service of Mr. Stanley Boyd. Carbolic-acid intoxication was possible predisposing factor. Operation for double genu-valgum; lasted one hour and ten minutes. Chloroform anesthesia. The symptoms were vomiting, restlessness and coma. Death occurred fifty-three hours after anesthetic.

Autopsy.—Liver small, weighing 1 pound 3 ounces.

Case 7.—Female child, aged 4, well nourished and apparently healthy. Service of Mr. Stanley Boyd. Chloroform anesthesia; chloroform taken badly. Iliac abscess was opened and 2 ounces of 10 per cent. iodoform glycerin emulsion were injected. Collapse after operation. The symptoms were incessant vomiting; child either apathetic or extremely restless and delirious. Carboluria noted. Death occurred six days after operation. Temperature shortly before death reached 104.6.

No autopsy permitted.

Case 8.—Female child, aged 2. Service of Mr. Watson Cheyne. Child was apparently in good health; iliac abscess was opened under chloroform. Anesthesia lasted about fifteen minutes, and one-half ounce of chloroform was taken well. Twelve hours after operation the child was dull and apparently in shock. Death occurred fourteen hours after operation.

Autopsy.—Peritoneum congested. Some fluid found about abscess. "No apparent cause of death."

Case 9.—Female child, aged 8½. Service of Mr. Watson Cheyne. No predisposing cause. Psoas abscess was opened under chloroform and irrigated with 1-4,000 bichlorid solution. The child was pale and restless after operation. The symptoms were severe abdominal pain, nausea and vomiting; diarrhea with some blood in stools. Temperature 95.8. The symptoms persisted for three days, then abated, and recovery followed. Judging from the character of the symptoms and the use of bichlorid in the operation, it seems that mercurial poisoning should be considered in this case.

Case 10.—Female child, aged 4. Service of Mr. Pollard. Operation under chloroform for double psoas abscess and spinal caries. Operation lasted about one hour. Symptoms were noted four hours after operation. Child was very restless, calling for water; flushed; pulse full. Sixteen hours after operation child was restless, with wild look; temperature 103. Death occurred sixteen hours after operation.

Autopsy.—Liver large and pale; fatty on section. Kidneys soft and pale (postmortem). Tuberculous glands about root of lung; one had ulcerated into root of lung. Calcareous tubercles in lung. Caries of body of third lumbar vertebra.

(To be continued.)

OSSIFICATION OF THE LOWER JAW IN MAN.*

EDWARD FAWCETT, M.B. (Edin.)
Professor of Anatomy, University College.
BRISTOL, ENGLAND.

From the fact that there are so many different accounts given of the ossification of the lower jaw, it is evident that the question is in need of reinvestigation. Nothing more recent than Bland-Sutton's account seems to have been published on the subject, and that is based on work apparently done in 1883[1] and, as will be seen, it can be by no means considered conclusive.

It is necessary to state the various accounts as the recognized text-books give them in order to appreciate the great diversity of opinion which exists.

If we begin with Quain, we find the following statement:

> The largest part of each half is formed from a deposit (dentary) in the membrane on the outer side of Meckel's cartilage, and to this there is added a second smaller plate (splenial) which forms the inner walls of the tooth sockets, terminating behind in the lingula. A small part of the body by the side of the symphysis results from the direct ossification of the anterior end of Meckel's cartilage; and, posteriorly, the condyle and a portion of the ramus, including the angle, are developed from another ossification in cartilage.

Macalister[2] says:

> One center of ossification begins in the embryonic tissue around Meckel's cartilage on the thirty-eighth day. A supplemental patch of cartilage appears in this tissue at the angle and a second at the condyle. Centers of ossification, condylar and angular arise in each of these patches, and a third in the median end of Meckel's cartilage; a fifth or splenial center arises in the lingula. These all very rapidly unite, so that by the fourteenth week but one bony mass is present on each side.

Kollman,[3] who quotes Toldt,[4] Stieda[5] and Schafer,[6] says that the anlage of the lower jaw can be seen in an embryo of 30 mm. from neck to tail. The ventral site of union of both Meckel's cartilages is surrounded by bony lamellæ which arise, not out of cartilage, but out of mesoderm and develop upward, following Meckel's cartilage. They form at the side two bony lamellæ, which come together dorsally, and between the lamellæ runs the inferior dental nerve. Further upward, the bone becomes thinner, to again thicken in the neighborhood of the auditory capsule. There are few places where one can so clearly observe the independence of covering bone from that arising from cartilage. Further, the origin of the jaw becomes complicated through the appearance of hyaline cartilage, which arises secondarily, quite independently of Meckel's cartilage. This occurs in the region of the median incisor tooth from the upper external alveolar border as far as the region of the canine tooth and on the coronoid and condyloid processes.

4. Toldt: Zeitft. d. Heilk. Vol. v, 1884.
5. Stieda: Arch. f. mikroskop. Anat., vol. ii, 1875.
6. Schaffer: Arch. f. mikroskop, Anat., vol. xxxii, 1888.

In the fetus of from 15 to 18 cm., only traces (of cartilage) are present, and these accessory nuclei have only a provisional significance. They atrophy, owing to the formation of new bony tissue, just as does Meckel's cartilage. Fresh researches are required to determine whether these ossifications have any phylogenetic meaning.

In "Gray's Anatomy," in the article edited by Howden, the following statements are made:

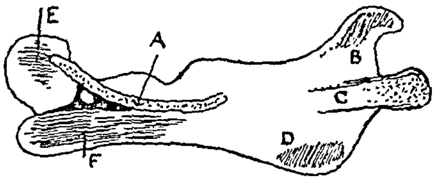

Fig. 1.—Scheme after Sutton. E. Mento-Meckelian center. F. Dentary. A. Splenial. B. Coronoid. C. Condyle. D. Angular.

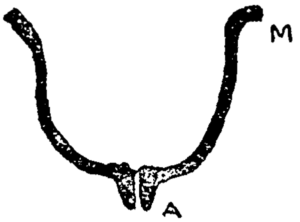

Fig. 2.—Scheme of Meckel's cartilage: M, malleus end; A, anterior end.

> The lower jaw is developed principally from membrane, but partly from cartilage. The process of ossification commences early, earlier than any other bone, except the clavicle. The greater part of the bone is formed from a center of ossification (dentary) which appears between the fifth and sixth weeks in the membrane on the outer surface of Meckel's cartilage. A second center (splenial) appears in the membrane on the inner surface of the cartilage, and from this center the inner wall of the sockets of the teeth is formed; this terminates above in the lingula. The anterior extremity of Meckel's cartilage becomes ossified, forming the body of the bone on each side of the symphysis. Two supplemental patches of cartilage appear at the condyle and at the angle, in each of which a center of ossification for these parts appears; the coronoid process is also ossified from a separate center. At birth the bone consists of two halves united by a fibrous symphysis in which ossification takes place during the first year.

In Cunningham's "Text-book of Anatomy," p. 141, we find it stated that:

> The development of the lower jaw is intimately associated with Meckel's cartilage, the cartilaginous bar of the first visceral or mandibular arch. Meckel's cartilages, of which there are two, are connected proximately with the periotic capsule and cranial base. Their distal ends are united in the region of the symphysis. It is from the connective tissue overlying the outer surface of the cartilaginous arch that the bulk of the lower jaw is developed. The cartilage itself is not converted into bone, but undergoes resorption, except at its anterior extremity, which is stated to undergo ossification to form the part of the jaw lying between the mental foramen and the symphysis. In a third or fourth month fetus, the cartilage can be traced from the under surface of the forepart of the tympanic ring downward and forward to reach the jaw, to which it is attached at the opening of the inferior dental canal; from this it may be traced forward as a narrow strip applied to the inner surface of the mandible which it sensibly grooves. The proximal end of this furrow remains as the mylo-hyoid groove. The part of the cartilage between the tympanic ring and the jaw becomes converted into fibrous tissue and persists in the adult as the so-called internal lateral ligament of the temporo-maxillary articulation, its proximal end through the Glaserian fissure being continuous, with the slender process of the malleus. The part which is applied to the lower jaw disappears. In the tissue overlying the cartilage ossification begins by several centers as early as the sixth or seventh week of fetal life, in this respect resembling the clavicle, by which it is alone preceded. The dentary or basal center forms the outer wall and lower border. With this is united the splenial portion, which appears somewhat later, forming the inner table from near the symphysis backward, toward the opening of the inferior dental canal, where it terminates in the lingula. By the union of these two parts a groove is formed, which ultimately becomes covered in, and in which the inferior dental nerves and vessels are lodged. As has already been stated, the part of the body between the symphysis and the mental foramen is regarded as directly developed from the forepart of the Meckelian cartilage. As will have been gathered from the above description, the upper part of the ramus and its processes have no connection with Meckel's cartilage; the condyle and the coronoid process are each developed from a separate center, preceded by a cartilaginous matrix. These several centers are all united about the fourth month.

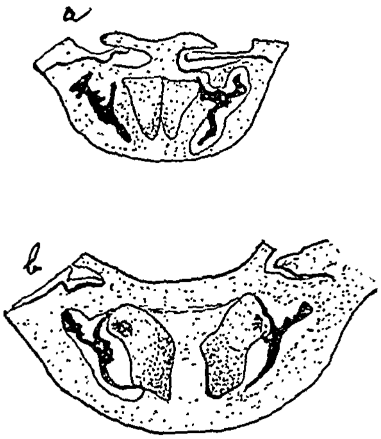

Fig. 3.—(a) Coronal section of anterior end of Meckel's cartilage. (b) Coronal section a little behind anterior end of Meckel's cartilage.

Sappey[7] describes very carefully Meckel's cartilage and, in addition, gives an account of the ossification of the lower jaw. He says:

> The lower jaw appears at the commencement of the second month of intrauterine life in the form of a small ogival arch, composed of two symmetrical and continuous halves. This arch of parabolic figure constitutes the cartilage of Meckel. . . . Situated on the internal face of the bone below the mylo-hyoid ridge, Meckel's cartilage presents the appearance of a long ribbon extended between the symphysis and the front of the tympanum. By their internal extremities the two cartilages are continuous; they form thus an arcade of which the median part sends a prolongation between the two halves of the maxilla. Their external extremity projects be-

---

[7] Fourth edition, 1888, p. 241.

yond the corresponding bony part and applies itself to the anterior part of the tympanic ring and penetrates into the cavity of the tympanum. . . . Ultimately Meckel's cartilage disappears, first in its intermediate part, then at its anterior extremity; only the posterior part remaining as the malleus and incus. In front of the cartilage of Meckel appear two centers of ossification in a cartilage not well known, one right, the other left, toward the thirty-fifth day. They extend *rapidly along the whole length of each half of the bone.*

Testut,[8] who quotes from Kolliker, Brock, Masquelin[9] and Julin,[10] says that the lower jaw is primitively *double, that each half is developed quite independently* of the other, and that the bone which covers it does so just as the bones of the membranous cranium cover the primitive chondrocranium. He states, too, that the osseous condyle is preceded by a cartilaginous condyle. Thus, each half is a mixed bone, developing partly from embryonic connective tissue and partly from pre-existing cartilage. Agreement on this point is not complete and the method of development of the mandible, especially that of the condyle, requires new researches.

Testut states that, according to Rambaud and Renault, each half of the jaw has six ossific centers visible from the fiftieth day of intrauterine life.

1. The inferior point (visible at the thirtieth or thirty-fifth day), a small train of osseous granules, situated toward the inferior border of the bone.

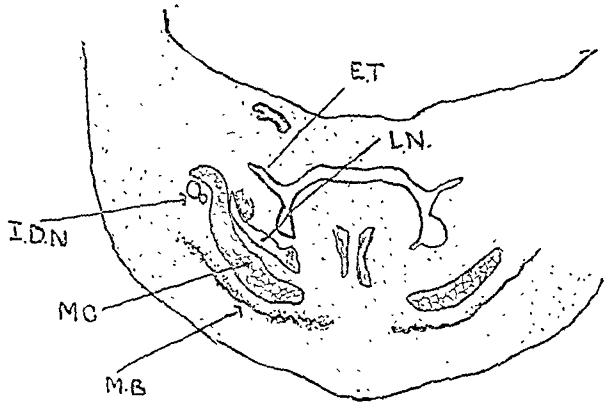

Fig. 4.—(Harvard collection, 852, H., 129) Horizontal section of 21 mm. embryo. M. C. Meckel's cartilage; I. D. N., inferior dental nerve; L. N., lingual nerve; E. T., Eustachian tube; M. B., membrane bone.

2. The invisive point, situated on each side of the symphysis in the region which the incisors will occupy later.

3. The supplementary point of the mental foramen, which helps by its inferior surface to form the mental foramen.

4. The condyloid point, which will form the condyle and subjacent portion of the ramus.

5. The coronoid point, out of which will develop the coronoid process and the portion of the ramus which forms its base.

6. The point forming the spine of Spix, situated on the posterior surface of the bone from the superior orifice of the future dental canal as far as the incisive piece.

According to Cruveilhier.[11]

The inferior maxilla is developed by two points of ossification, one for each lateral half. Autenrieth admits, in addition, three complementary points, one for the condyle, one for the coronoid process and one for the angle, but I have never observed them. The case is different, however, with a point of ossification described and figured by Spix, which forms the inner side of the alveolar border or rather of the dental canal. In a fetus of about fifty or sixty days, I have seen a kind of bony spiculum which passed along the internal surface of the body and ramus of the bone. On one-half of the maxillary bone this spiculum was entirely free, but that of the other side adhered by the internal third of its length. The spine which surmounts the dental canal is nothing more than the extremity of this bony spiculum. It follows, therefore, that the inferior maxilla is developed from four points of ossification. The inferior maxilla takes precedence of all the bones of the head in its development and, indeed, of all the bones of the skeleton, except the clavicle. The inferior edge of the body of the bone appears as early as the thirtieth or thirty-fifth day. This extends backward to form the ramus and forward to form the portion which supports the incisor teeth. It is probable that the osseous point of the dental canal, mentioned above, appears at the same time. At a later period the groove becomes very considerable and is divided into alveoli by septa which at first are incomplete, but afterward become perfect; the alveoli and their septa occupy at this time *the entire depth of the bone.*

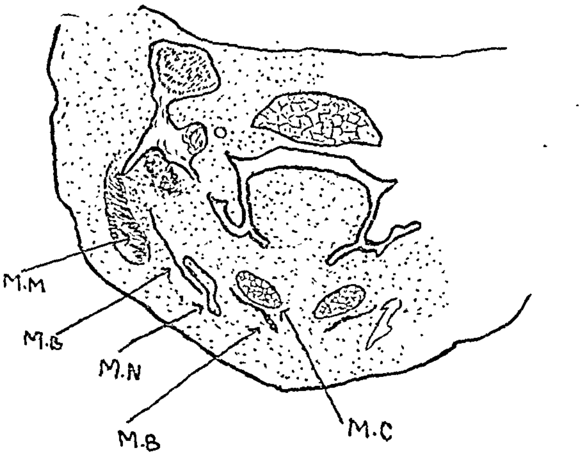

Fig. 5.—(Harvard collection, 852, G., 112.) Horizontal section of 21 mm. embryo. M. C., Meckel's cartilage; M. N., mental nerve; M. B., membrane bone; M. M.

The point of ossification described by Spix is united to the rest of the bone from the fifteenth to the sixteenth day. (Spix affirms that it remains separate until the fourth month.) The two halves of the maxilla are joined together during the first year after birth, the traces of this union exist for some time, but are afterward effaced in the lower animals; the suture remains throughout life.

According to Humphry,[12] "ossification commences in the membrane from which the inferior maxilla is formed at a very early period, from the thirtieth to the thirty-fifth day, according to Beclard. Soon after two months, it is considerably advanced. The bone is then in two halves, united in the median line by membrane. In each of these halves, the condyle, coronoid portion and angle are quite evident, the mental part is of considerable size, and there is a lamina appended to the inner side of the ramus, which, shooting upward, forms the inner wall of the dental groove and dental canal. The appearance of the several parts at this early stage certainly gives countenance to the supposition that each of them had a separate ossifying nucleus, corresponding, or nearly corresponding, with the five pieces into which the jaw of the crocodile is permanently divided; that is to say, one for the under and outer part of the ramus, another for the inner alveolar border, a third for the coronoid process, a fourth for the condyle, and a fifth for the angle. If it be so, they become united very quickly after their formation. The probability, however, is that in this bone, as in the upper jaw, there is usually only one nucleus on either side and that the various processes are merely outgrowths; the instances in which the latter are developed from the separate nuclei being exceptional.

[12] A Treatise on the Human Skeleton. 1858, p. 290.

Kerkringius[13] describes the coronoid process as consisting, up to the third month, of an ossicle, separated by a suture from the rest of the maxilla. Beclard mentions, in addition to the nucleus for the ramus, which appears from the thirtieth to the thirty-fifth day, a nucleus for the coronoid process, which appears about the forty-fifth day. Autenrieth and Spix[14] describe also a nucleus for the condyle and one for the angle, to the probability of which Beclard gives assent. According to Spix, the inner wall of the jaw is derived from a separate nucleus. Blandin[15] found the body, the coronoid process and the hinder part of the bone separate from one another in a fetus of three months. As growth proceeds, the inner lamina of the ramus rises nearly to the same level with the outer and forms the inner alveolar border; the dental groove is deepened:

> Near the coronoid process the inner lamina joins the outer, arching over and enclosing the dental foramen and the hinder part of the dental canal. The latter is at this time a mere channel in which the nerves and vessels lie, at the bottom of the dental groove, in the greater part of its extent.

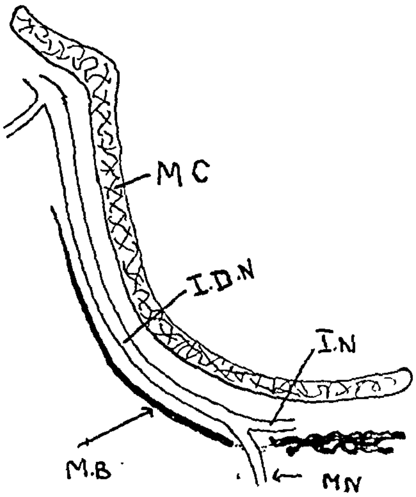

Fig. 6.—Schematic horizontal section of Meckel's cartilage; the inferior dental nerve. I. D. N., and the membrane bone, M. B. M. C., Meckel's cartilage; M. N., mental nerve.

Cleland[16] says:

> The lower jaw is, next to the clavicle, the earliest bone to show osseous deposit. It is developed round Meckel's cartilage, mainly outside of it, but additional centers have been noted at the lingula, at the angle, at the coronoid process and at the condyle. The condyle is laid down in cartilage before its ossification begins, but the supposition that Meckel's cartilage is in any part converted into osseous tissue of the jaw is erroneous.

Holden[17] says:

> Each lateral half of the lower jaw is represented in the early fetus by what is called the "first visceral arch or cartilage of Meckel." In the process of development, the proximal part of this cartilage is converted into the "malleus" bone of the middle ear. The distal part, mostly by the growth of bone round the cartilage, but slightly by a direct ossification of the cartilage itself, is converted into one-half of the lower jaw. The part between these two end portions becomes the "internal ligament" of the temporomaxillary articulation. The bony lower jaw begins to be formed, with perhaps the exception of the clavicle, earlier than any other bone in the body. For each of the lateral halves of the bone, we find that several osseous nuclei appear about the sixth week of fetal life in the membrane which invests Meckel's cartilage. The smaller plate forms the inferior dental canal and the inner wall of the sockets for the teeth. The symphysis end of each half of the body is formed by a direct ossification of the corresponding part of Meckel's cartilage. The condyle and part of the vertical ramus are formed by ossification of cartilage not connected with Meckel's, and the junction of the two lateral halves of the body at the symphysis does not take place till the first year after birth.

In 1883, Bland-Sutton[18] published a paper giving a very excellent and concise résumé of the work which had already been done on the subject and also giving the results of his own observations. He says:

> The examination of numerous specimens of human maxillæ from the sixth week onward has convinced me that the lower jaw arises from six distinct centers of ossification, five of them answering exactly to those described by Spix, the sixth representing the mento-Meckelian center of Callender.
>
> So far as I have been able to observe, the nucleus marked F. in Figure 1 is the first to appear; from this center the larger part of the body of the bone is formed. At first it resembles a shallow trough lodging the cartilage.
>
> The nuclei for condyle, coronoid and angle follow so rapidly that it is difficult to determine their order. About the same time, osseous granules may be seen in the perichondrium surrounding the distal end of Meckel's cartilage, gradually invading its substance.
>
> As soon as the various centers make their appearance, a thin network of osseous tissue quickly connects them. When this occurs a thin shelf of bone will be found immediately above Meckel's cartilage and the inferior dental nerve. This latter osseous streak lies on the inner side of the developing bone, quite distinct from the other centers, and represents the splenial. Now is the very best time to observe the various nuclei, particularly if the bone is rendered transparent by means of alcohol and oil of cloves. Its appearance is very striking. The bone presents the familiar shape of the fetal jaw, but its texture reminds one of a spider's web, the various centers showing like flies entangled in the mesh. (Fig. 1.)
>
> The order of events may be arranged in stages for the sake of clearness thus:
>
> 1. Meckel's cartilage appears.
> 2. Dentary is seen below.
> 3. Centers for condyle, coronoid, angle and mento-Meckelian.
> 4. Network of osseous tissue connects them together.

5. Splenial appears as ledge of bone supporting teeth.
6. Disappearance of Meckel's cartilage from jaw, and fusion of splenial.

The splenial element is interesting on account of its relation to the developing teeth. On its first appearance it stands out at right angles to the dentary, serving to separate the teeth germs from Meckel's cartilage. If, at the fourth month of intrauterine life, the tissues on the inner side of the jaws be carefully dissected away, the splenial will be observed forming a distinct ledge of bone, supporting on its superior surface the dental follicles like flasks on a shelf; immediately beneath it runs Meckel's cartilage and the nerve. As the cartilage atrophies, the splenial extends downward to fuse with the dentary immediately below the nerve; in this way the mylohyoid branch gets shut off from the main portion of the inferior dental nerve. After the fourth month it extends vertically to form the inner wall of the maxilla, all trace of its originally separate condition being thus completely lost, the bone then assuming the condition which it presents at birth and with which we are all so familiar.

Let me now offer evidence of the compound nature of this bone of a different character. In the year 1814, the celebrated French anatomist, Serres, in a paper read before the Académie des Sciences, Paris, propounded certain laws bearing on ossification. Among them was one termed the "Loi de Conjugaison," by which he showed the various foramina in bones to result from the opposition of two or more distinct bones or distinct centers of ossification. To this law there were many exceptions; among the more unstable were certain foramina in the temporal bone and the inferior dental foramina.

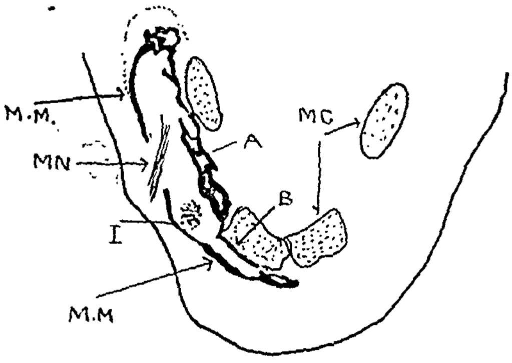

Fig. 8.—Horizontal section of 42 mm. embryo showing the growth of the inner alveolar border. M. M., primitive membrane bone; M. N., mental nerve; I., canine tooth; A., inner alveolar border; B., inner segment of that border; M. C., Meckel's cartilage.

When I first took up the subject of nerve foramina, Serres' researches were quite unknown to me, and I took as my guide this rule: "Whenever a nerve passes through a bone it marks the confluence of two or more ossific centers." Among the earliest bones to yield under this method of analysis were the temporal and the inferior maxilla; later I became acquainted with Serres' paper, the greater part of which is published as a footnote in the French traduction of Meckel's "Anatomie Comparée, vol. iv. Much to my satisfaction, I found that my method had yielded far more satisfactory results and had banished two of the apparently most obvious exceptions to the law, and it is most interesting to trace out the intricate pathways by which many nerves quit the cranial cavity in order to avoid piercing an ossific center.

Applied to the lower jaw, the rule stands thus: The nerves concerned are the inferior dental, mental and mylohyoid. The inferior dental enters by the foramen of the same name, formed by the coalescence of the coronoid, condyloid, dentary, angular and splenial elements; the nerve then travels in a tunnel formed on the outer side of the dentary and on the inner side of the splenial. The mental branch passes out through a fenestrum formed by dentary and mento-Meckelian ossification.

The mylohyoid runs in the groove which once lodged Meckel's cartilage, the sulcus, also corresponding to the junction of splenial with dentary. As the inferior dental passes along the canal, it sends up twigs to the teeth, and these twigs occupy foramina or spaces between the splenial and dentary. The relation of nerves thus lends additional help in unraveling the mystery.

Mr. Sutton, from this point, proceeds to the comparative side of the question, quoting the condition in the dogfish, the sturgeon, the *ganoid amia,* the cod, amphibia and reptiles. He finally gives a table of homologies thus:

HOMO.	FISH.
Mento-Meckelian.	Mento-Meckelian.
Angle.	Angular.
Condyle.	Articular.
Coronoid.	Surangular.
Splenial.	Splenial.
Dentary.	Dentary.

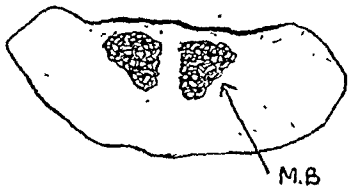

Fig 9.—(Harvard collection. 819, Q., 233.) Coronal section of 19 mm. embryo; M. B., membrane bone.

I have quoted Mr. Sutton's paper as fully as possible, because it is practically the most recent work on the subject and for reasons which I may explain later.

My own observations on the subject commenced several years ago. In cutting a section of the neck of a three months' fetus for examination of the developing larynx from above downward, the appearance of the developing jaw was such that it was evident that the last word had not been said on its ossification. Having made observations of one or two facts, namely, that Meckel's cartilage did ossify and that the so-called dentary center extended right up to the middle line (symphysis), I had to rest content, having no material available by which I might test the accuracy of statements made with regard to other centers of ossification in the lower jaw. Latterly, however, I have come into possession of fresh material, for some of which I have to thank Dr. Keith of the London Hospital, for much other material, several old pupils, and for many valuable sections, made especially for this research, Prof. C. S. Minot of Harvard University, who has taken the greatest possible interest and trouble over the matter. Many of the figures illustrating this paper are from sections supplied by him, and I very gladly take this opportunity of acknowledging his great kindness and at the same time the usefulness of the Harvard embryologic collection, which apparently is at the disposal of any responsible worker.

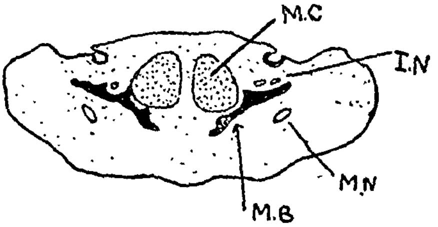

Fig. 10.—(Harvard collection, 819, P., 323.) Coronal section of 19 mm. embryo; M. C., Meckel's cartilage; M. B., membrane bone; M. N., mental nerve; I. N. incisive branch of mental nerve.

PERSONAL OBSERVATIONS.

In spite of the fact that I have come into possession of much new material, I am bound to say that I am not in a position to state exactly at what time ossification really begins, but I have cut embryos of from 12 to 15 mm. in length which may be reckoned as five and one-half weeks, and have seen no bone; ossification, however, is well advanced in embryos of from 19 to 21 mm. in length, so one may say that it occurs perhaps in the 17 mm. embryos. That, however, is not very important. It is rather to state the nature of the ossification and the number of centers of ossification which arise that this research has been undertaken.

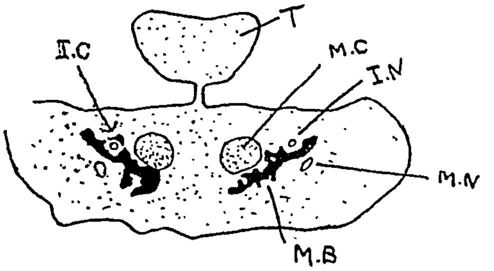

Fig. 11.—Coronal section of 19 mm. embryo; in front of mental foramen. incisor canal is just forming: M. B., membrane bone; M. N., mental nerve; I. N., incisive nerve; T. tongue; M. C. Meckel's cartilage.

We have seen the variety in the various accounts given in the text-books, and it remains for me to show if these accounts are accurate. In order to test these statements, sections have been made in various planes of embryos ranging from 19 mm. in length to over 100 mm., all sections being serial.

As is well known, Meckel's cartilage forms a very prominent object during the early stage in the development and ossification of the jaw, and until bone actually appears is for all practical purposes the lower jaw itself. Soon, as we have already seen, it becomes covered by ossification in membrane on its outer side, and from that time forward its importance diminishes and it ultimately disappears, except proximally and distally; proximally forming at least the malleus, and distally becoming an integral part of the bony jaw, for the time being at all events.

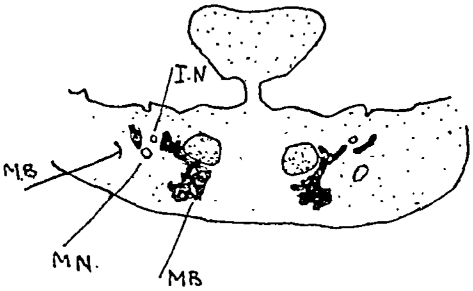

Fig. 12.—(Harvard collection, 819, P., 313.) Coronal section of 19 mm. embryo through mental foramen; M. N., mental nerve; I. N., incisive nerve.

As accounts given of Meckel's cartilage in man convey but little accurate information, and seeing that is such an important element in the formation of the jaw, it may not be out of place to make some remarks concerning it. It is somewhat late in appearance, for, although one can make out its anlage in precartilaginous conditions in the 12 to 13 mm. embryo, it does not become cartilaginous until after the femur does. This is not what one would expect, seeing that it is such an archaic structure.

When formed, the two cartilages (when seen in horizontal sections) form a horseshoe, incomplete in front, at first being separated by an appreciable interval; soon, however, they meet in the middle line, and later usually overlap one another there. Each cartilage is thickened in the vertical sense on each side of the future symphysis (see scheme of cartilage, Figs. 2 and 3). If we trace the cartilages backward from this anterior thickening, we find that they form a large bend, with the convexity outward, and still further backward form another bend, with the concavity outward, before ending in the malleus. The latter bend is found in front of the Eustachian tube. In its concavity lies the inferior dental nerve, and against its convexity the lingual nerve (Fig. 4).

FATE OF MECKEL'S CARTILAGE.

The posterior or proximal end becomes converted into the cartilaginous malleus, the anterior or distal end from about the level of the mental nerve becomes incorporated in the jaw and undergoes ossification. The remainder disappears completely. It is generally stated that a part, that stretching between the lingula of the lower jaw and the malleus, becomes the internal lateral ligament of the jaw, but that, I think, is more than doubtful, as one can see the ligament quite well developed at the same time that the cartilage is also well developed, the latter lying in a groove on the inner side of the former. In the transverse horizontal section of the head of a 42 mm. fetus, the two structures appear to be quite independent of one another. So much for Meckel's cartilage for the present; it may be referred to later.

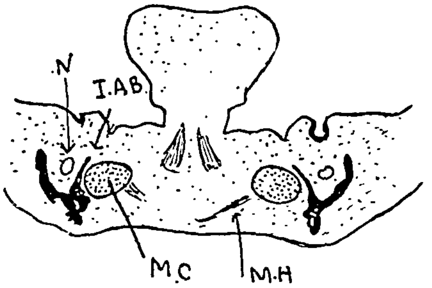

Fig. 13.—(Harvard collection, 819, O., 305.) Coronal section of 19 mm. embryo behind mental foramen to show inner alveolar border, I. A. B.; I. D. N., inferior dental nerve; M. C., Meckel's cartilage; M. H., mylo-hyoid muscle; N., inferior dental nerve.

We may now examine the appearance presented by the membrane bone, and that may be best done by examination of horizontal sections primarily, then of corneal ones corrected from time to time by sections cut sagittally.

HORIZONTAL SECTIONS.

These sections were cut by Prof. Minot from an embryo measuring in length 21.8 mm. and were stained with alum cochineal and alum hematoxylin—the latter only being effective. They yielded most interesting results.

In one section (Fig. 4) one can see Meckel's cartilage M. C. sweeping backward and outward; in its anterior concavity is the lingual nerve L. N., and in the concavity of the outwardly directed posterior end of the cartilage is the inferior dental nerve, I. D. N. Behind the lingual nerve is the Eustachian tube. All these, but especially

Meckel's cartilage and the inferior dental nerve and its terminal branches, are important landmarks. Figure 5 is cut a little higher up than Figure 4. It shows the anterior end of Meckel's cartilage, M. C., in front of which is membrane bone, to the outer side of which is a nerve—the mental, M. N. This is succeeded by another strip of membrane bone, M. B., giving an appearance as if there were here two centers of ossification. These two patches of bone are continuous below the mental nerve, as in Figure 4, and appear as one strip thicker near the middle line than elsewhere.

From what one can see in Figures 4 and 5 and in the scheme (Fig. 6), it appears that ossification has commenced in front of the anterior expanded end of Meckel's cartilage and the incisive branch of the inferior dental nerve, and has extended backward under the mental nerve, M. N., as a strip of bone rapidly diminishing in thickness, and consequently looking more faintly stained than that near the middle line. It is in close relation with the antero-external aspect of the inferior dental nerve and its incisive branch. No trace of any bone is to be seen on the inner side of these nerves at this time. In other words, there is not at this time developed an internal alveolar border. This, however, very rapidly appears, and its method of appearance is of great importance, as it involves the question of the separate origin of that part of the bone. Some authors, whose observations have certainly not been based on serial sections, e. g., Spix, Cruveilhier, Renault and Rambaud and Sutton, describe a separate ossific center for the splenial, as Sutton calls it. We will be able to see, however, that this inner alveolar border does not commence in that way, but arises by ingrowth from the main mass just behind the mental nerve in the form of an obliquely directed shelf, which comes to a point behind the "lingula." This shelf insinuates itself between the inferior dental nerve and Meckel's cartilage, coming to a point behind, as already said, and overhanging there Meckel's cartilage. At no time is it completely separate from the main mass, and it is, therefore, not an independent element —in other words, there is no splenial center.

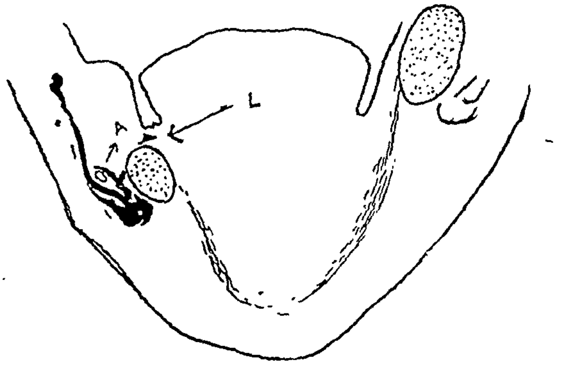

Fig. 14.—Showing formation of inferior dental canal at posterior end by a piece, A, growing outward from inner alveolar process. L. is the lingula.

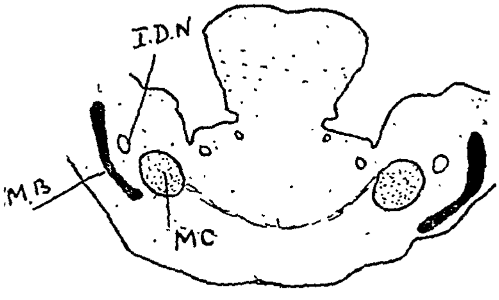

Fig. 15.—(Harvard collection, 819, N., 287.) Coronal section of 19 mm. embryo. I. D. N., inferior dental nerve; M. C., Meckel's cartilage; M. B., membrane bone.

At first, there is *no inner alveolar border* behind the incisive nerve, but there grows backward over Meckel's cartilage and under the incisive nerve near its origin from the inferior dental nerve, a shelf. In Figure 7 (my own collection), this shelf, A. B., can be seen growing backward over Meckel's cartilage, M. C., and under a tooth germ (second incisor). The inner alveolar border, then, arises from the main mass in two ingrowths, first, one under the inferior dental nerve, which enlarges in the backward direction and ends ultimately at the lingula, the other growing under the outer end of the incisive branch of the inferior dental nerve and extending inward toward the middle line.

In Figure 8 (my own collection), a horizontal section of the head of a 42 mm. embryo, M. M. represents primitive membrane bone forming the outer alveolar border. M. N. is the mental nerve. I. is the canine tooth. A. is the posterior segment of the inner alveolar border much reticulated and, therefore, in an advanced state of ossification, whereas B is the anterior segment of that border existing only as a thin lamella and developing somewhat later. It will be to our advantage to examine a series of coronal sections of a 19 mm. embryo cut by Prof. Minot and corrected by others of a later date cut by him and by myself. If such be examined from before backward, very instructive views are obtained both of the manner of growth of the formative bony center and its subsequent extensions.

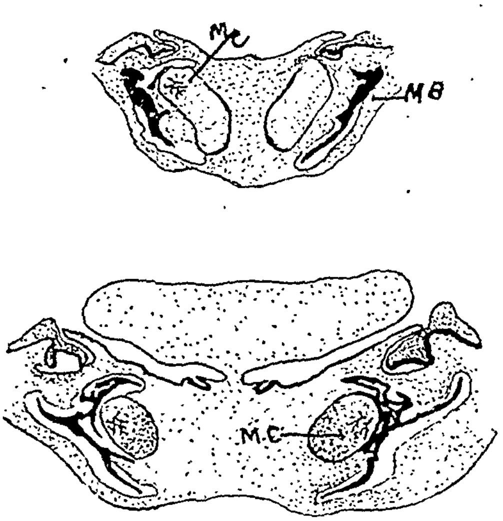

Fig. 16.—(a) Meckel's cartilage ossifying; M. B., membrane bone. (b) Shows upper and lower shelves, which ensheath Meckel's cartilage.

In Figure 9, one can see on each side of the middle line a mass of membrane bone which lies in front of the anterior expanded end of Meckel's cartilage and extends to the middle line, not, as Sutton thinks, stopping short at the mental nerve. He says that all that part of the mandible anterior to the mental foramen is ossified from Meckel's cartilage. This section, and others, notably one of the third month, cut horizontally, *show* that the membrane bone reaches *to the middle line*

(Figs. 9 and 8), *and that Meckel's cartilage does not* ossify as yet up to the middle line.

In Figure 10, we have still no inner alveolar border, the two cartilages of Meckel are altering their shape. M. C. is Meckel's cartilage. M. B. is membrane bone outside it. M. N. the mental nerve, and I. N. the incisive branch of that nerve.

In Figure 11, which is just in front of the mental foramen, one sees Meckel's cartilage more widely separated and more circular in form; on the outer side of them one sees the membrane bone M. B. jutting upward and outward between the mental and incisive nerves, M. N. and I. N. In the left half of the section, one can see the incisive nerve being enclosed in a canal—the incisive canal I. C. There is no inner alveolar border in this section. In Figure 12 the jaw is cut through at the mental foramen. The membrane bone here seems to be in two parts and one might think that there were two centers of ossification, but in the subsequent sections we will find that is not the case—M. B. is membrane bone, M. N. the mental nerve, and I. N. the incisive nerve. The two nerves here mark the mental foramen.

In Figure 13 the jaw is cut behind the mental foramen and one now sees an alveolar border passing up between the inferior dental nerve N. and Meckel's cartilage M. C., it is evidently a shelf and an outgrowth from the main mass. This inner alveolar border comes to a point behind, hence when cut coronally that point appears detached (Fig. 14, my own collection) and simulates a separate splenial.

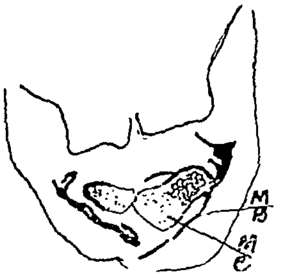

Fig. 17.—Coronal section at third month, showing ensheathing of Meckel's cartilage by membrane bone. M. C., Meckel's cartilage; M. B., membrane bone.

Still further back (Fig. 15) the inner alveolar border has disappeared and the jaw is once more unilamellar, having to its inner side Meckel's cartilage, M. C., and the inferior dental nerve, I. D. N. Still further back one may see the condyle in a procartilaginous condition, but no drawing is given of this, the coronoid process is also evident, but quite thin and it can be seen to be an ossification of that fibrous blastema which lies like a wedge between the masseter and temporal muscles at this early stage of life; it is perhaps more in connection with the temporal muscle than the masseter that it is developed.

So far, then, we have seen a jaw consisting of Meckel's cartilage and a membrane bone, which stretches to the middle line in front, and behind the mental nerve gives off a shelf—the internal alveolar border. We have seen that the coronoid process, and for that matter too, the angle, are thin, and that the condyle is not yet ossified. Very soon this membrane bone increases in amount, it has already done so in front and where ossification first took place, Figure 6; it now thickens and becomes reticulated in the region of the angle, the top of the coronoid process and in that part of the inner alveolar border which is developed behind the nerve. It is now that those false impressions may arise from the employment of crude methods such as that of Sutton, who, removing one-half of the jaw from a fetus, immersed it in alcohol and cleared it with balsam and saw centers for "dentary," "condyle," and "coronoid," as well as a separate "splenial" center. Serial sections will show the falsity of conclusions drawn from the employment of such a method.

FURTHER CHANGES IN THE MEMBRANE BONE—THE FORMATION OF THE ROOF OF THE INFERIOR DENTAL CANAL.

This commences to be formed quite early in fetal life, in the neighborhood; first, of the mental nerve, then of the incisive branch of the inferior dental, and, considerably later, during the third month of fetal life it appears near the lingula. In each case, save that of the roof of the mental canal, it appears in the form of a spicule running from the inner alveolar wall to the outer. In Figure 11, Harvard collection, the incisive nerve can be seen lying in a canal or tunnel formed by a spicule of bone arching over it from what will become inner alveolar border to that which is the outer alveolar border. In Figure 14 (my own collection) there can be seen at A a spicule of bone which is growing outward over the inferior dental nerve to the outer bony lamella, and so covering over the nerve in the neighborhood of the permanent inferior dental foramen.

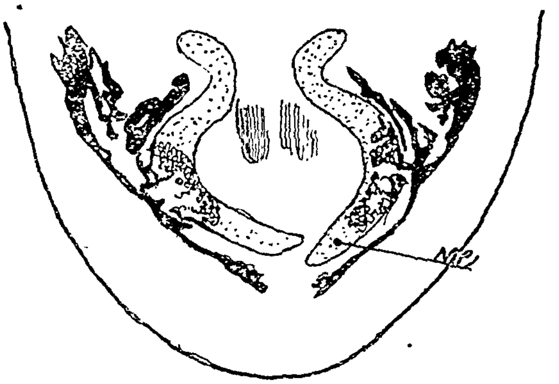

Fig. 18.—Horizontal section of jaw at third month, showing outward bend of Meckel's cartilage, M. C., and that cartilage undergoing ossification.

The inferior dental foramen is not, by the way, as Sutton would have us believe, formed at the junction of the coronoid angular, dentary, condyloid and splenial centers, for these centers are, for the most part, imaginary, certainly in the case of the coronoid, angular and splenial, and the condyle is so peculiarly formed as to be out of the question here. Sutton, too, would have us believe that the mental foramen is formed at the junction of his mento-Meckelian center, developed from Meckel's cartilage with the membrane bone which he calls dentary. We have seen that there is no such mento-Meckelian center such as Sutton describes and that the mental foramen is originally a groove on the top of the membrane bone which grows from before backward underneath the mental nerve.

In support of his theory with reference to the splenial center, Sutton quotes the mylohyoid nerve and states that it is shut off from the inferior dental by fusion of the "splenial" with the dentary. As a matter of fact, the mylohyoid nerve has reached its place before the inner alveolar border has grown to any extent backward.

FURTHER CHANGES IN THE MEMBRANE BONE.

These changes, so far as we are concerned here, involve its relation to Meckel's cartilage. Sections cut either coronally or horizontally show that Meckel's cartilage becomes invested with a covering of membrane bone, partly by ossification taking place in its sheath, partly by projecting shelves growing from the inner alveolar border and the undivided membrane bone below that. Then, in Figure 16—a, b—(my own collection), *Meckel's cartilage can be seen to lie in a* bony groove whose upper wall is from the inner alveolar border and the lower one from the main mass.

In Figure 17, ossification can be seen in the sheath of Meckel's cartilage. By the meeting of the upper and lower shelves and the fusion of the ossified sheath of Meckel's cartilage, the cartilage becomes included in front of the mental nerve within the jaw; behind the nerve it lies in a groove formed by similar shelves, which, however, never meet.

The septa between the tooth sockets are developed comparatively late in fetal life, that one behind the canine tooth appearing before the others. It can be very well seen in a four months' fetus. During this time, changes have been taking place in Meckel's cartilage itself.

OSSIFICATION OF MECKEL'S CARTILAGE.

About the tenth week of fetal life, ossification commences in Meckel's cartilage at a spot on its outer side corresponding with the site of the mental foramen, or even a little internal to this, and nearer the upper than the lower border of the cartilage. This ossification extends gradually inward, but does not completely involve anterior end of Meckel's cartilage until the time of birth even, as evidenced by the presence of cartilaginous masses which are well known in this situation (Figures 16, 17, 18).

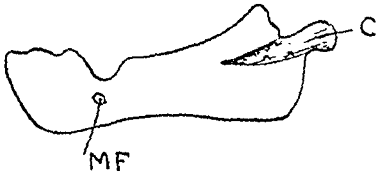

Fig. 19.—Scheme of left half of jaw, showing plug of cartilage, C., and mental foramen, M. F.

APPEARANCE OF ADDITIONAL CARTILAGES IN THE JAWS.

These are described in various places in the jaw. I have not myself seen all that have been described, but that is no reason for believing that they do not exist, the only question being their constancy. One, at least, of these cartilaginous masses is constant and it is of peculiar form, existing in the form of a plug, which enlarges to form the condyle proximally and tapers away distally to a point, having traversed the neck and root of the coronoid process of the jaw. This is shown in Figure 19, C being this plug of cartilage. It appears during the second and third months and very soon becomes calcified. It is enveloped everywhere except at the condyle by membrane bone and it becomes transformed into bone itself almost as soon as formed.

In Figure 20 (my own collection) one sees this cartilage undergoing ossification and being surrounded by a sheath of membrane bone; at the condyle B there is a part of cartilage as yet unossified and this is covered by a cap of fibrous tissue which, according to Hertwig, is permanent. *This plug of cartilage has never any connection with Meckel's cartilage.*

Recently, Dr. Low of Aberdeen,[19] in an excellent demonstration of the jaw ossification, showed a patch of cartilage along the anterior border of the coronoid process, but I do not know if that be constant. I, myself, have never met with it, but that may be because the material I have cut is too young.[20] Other patches are said to occur at the angle and at the outer alveolar border in the neighborhood of the incisor and canine teeth (Kollman).

CONCLUSIONS.

Having now examined various sections of the jaw and those of different ages, one may draw the following conclusions:

First.—The jaw in its ossification is not so complex as some would have us think, but it is for all that complex, involving (a) Meckel's cartilage at its anterior extremity, (b) the membrane on the outer side of Meckel's cartilage; (c) at least one accessory cartilage which is found in the condyle, neck and base of the coronoid process of the jaw. These statements apply to each half of the jaw.

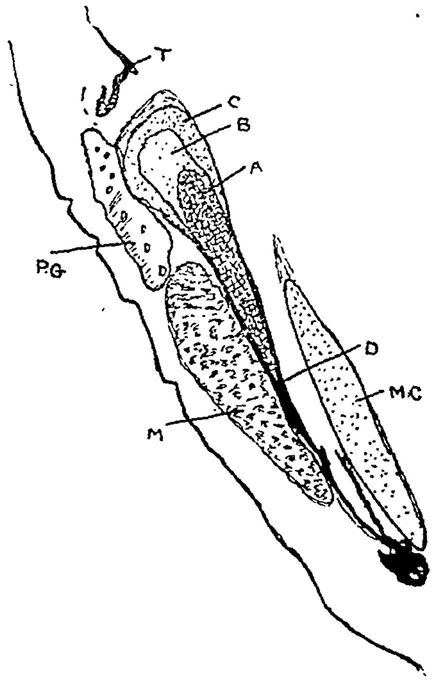

Fig. 20.—Horizontal section of three months head, through condyle and neck of jaw. D., ensheathing membrane bone; A., cartilage bone; P. G., parotid gland; M., masseter; M. C., Meckel's cartilage.

Second.—In order of sequence, ossification occurs first in the membrane between the mental nerve and the middle line and extends backward under the mental nerve. Next, ossification commences in Meckel's cartilage about the tenth week of fetal life in the region of the mental foramen and gradually extends inward. That part of the jaw then between the mental foramen and the symphysis is compound in origin, being partly cartilaginous, partly membranous, not entirely cartilaginous, as Sutton says. Finally, ossification takes place in the accessory mass of cartilage in the condyle neck and root of the coronoid process at the third month.

---

[19] Proceedings of Anat. Soc. of Great Britain and Ireland, May, 1905.

[20] Since this was written I have seen a specimen showing the cartilaginous strip along the anterior border of the coronoid process.

Third.—There are no separate centers in membrane for either the coronoid process or for the angle or the so-called splenial, all these parts being outgrowths, as it were, from the main mass.

Fourth.—The inner alveolar border is developed in two parts by ingrowth from the main mass and at two different periods. That part behind the mental foramen appearing first and elongating from before backward, that part in front of the foramen appearing later and growing from behind forward.

Fifth.—The canal for the nerves is completed by the growth of spicules from one alveolar border to the other over the top of the nerves, the mental nerve being first so covered, then the incisive, and much later the inferior dental near the permanent inferior dental foramen.

Sixth.—The sockets for the teeth become bony comparatively late, that for the canine appearing first.

Seventh.—Meckel's cartilage becomes incorporated in the jaw anteriorly by the development of upper and lower shelves, which gradually close over it; behind the mental foramen these shelves do not meet, and Meckel's cartilage is consequently not included in the jaw, but gradually atrophies.

Eighth.—I do not think that Meckel's cartilage atrophies to form the internal lateral ligament of the jaw. This ligament at the fourth month can be seen quite distinctly in an ordinary dissection to be independent of Meckel's cartilage.

All the figures except 2, 6 and 7 are camera lucida drawings.

STAPHYLOCOCCUS EXPERIMENTS.

The tables in Group 4 show the results of the experiments with cultures of *Staphylococcus pyogenes aureus:*

CONSIDERATION OF EXPERIMENTS WITH STAPHYLOCOCCUS.

1/1000 for *fifteen* minutes shows marked inhibitory effect. A and C show no growth throughout. On the second day B and D show fractional growth which increases gradually on the third and fourth days, when it equals less than ½ control growths.

1/1000 for *thirty* minutes gives a marked inhibitory effect. The first day there is no growth. On the second day A equals 1/6 control growth, B shows a point of growth, C is negative, and D gives 3/7 of control growth. On the third and fourth days B and C show simply a large point, while A and D give a gradual increase, equaling less than ½ control growth.

1/1000 for *sixty* minutes shows a marked inhibitory effect. On the first day there is no growth. On the second day A gives no growth, B and C give points, D equals control growth. On third and fourth days A shows no growth, B and C give no further development, D equals control growth.

1/500 for *fifteen* minutes shows an inhibitory effect. On the first day A, C, and D are without growth, B equals ½ control growth. On the second day the growth on experimental tubes equals 1/6 control growth. This growth increases slowly on the third and fourth days, when it equals 1/8 control growth.

1/500 for *thirty* minutes shows an inhibitory effect. A, C, and D show no growth the first day, while B equals 1/3 control growth. On the second day A, B, and C show less than ¼ control growth, D equals a point. On the third and fourth days D gives no further development, while A, B, and C show a gradual increase, which is less than ⅜ of control growth on the fourth day.

1/500 for *sixty* minutes exhibits an inhibitory effect. On the first day A, C, and D give no growth, B, equals ¼ control growth. On the second day A and B equal ¼ control growth, C shows a point and D shows no growth. On the third and fourth days A and B show rather rapid increase in growth, equaling ⅝ control growth on the fourth day. C shows a less rapid increase, equaling ¼ control growth. D shows points.

1/300 for *fifteen* minutes exhibits a marked inhibitory effect. On the first day there is no growth. On the second day A, C, and D give no growth, B equals 1/6 control growth. On the third and fourth days A and C show points, while B and D show slowly increasing growth, equaling about 1/3 control growth.

1/300 for *thirty* minutes shows a marked inhibitory effect. On the first and second days there is no growth. C and D show no growth throughout. On the third and fourth days A and B show a slightly increasing fractional growth, equaling about 1/7 control growth.

* Work done as Fellow in Surgery at the Senn Laboratory, Rush Medical College.

1/300 for *sixty* minutes shows a marked inhibitory effect. On the first and second days there is no growth. On the third and fourth days A, C, and D show a small fractional growth which increases slightly, equaling 1/7 control growth on the fourth day. B shows no growth throughout.

1/200 for *fifteen* minutes shows no growth.

1/200 for *ten* minutes shows no growth.

1/200 for *five* minutes shows no growth.

1/200 for *four* minutes exhibits a very marked inhibitory effect, A and D showing no growth. On the third day B shows points of growth and C a small fractional growth. On the fourth day there is a slight increase in both B and C. B showing more points of growth, while C equals 1/10 of control growth.

SUMMARY OF EVIDENCE ON STAPHYLOCOCCUS.

The death of the *Staphylococcus pyogenes aureus* occurs after an exposure of five minutes to a 1/200 solution of iodin. A consideration of the inhibitory action shows that this effect begins after an exposure to a 1/1,000 solution for fifteen minutes, where it is quite marked. This effect, however, increases but slightly for the longer exposure to this strength and also for all exposures to the 1/500 solution. Irregularity in action is observed. On using the 1/300 solution the inhibitive effect shows a great augmentation over preceding strength, which increases irregularly for time of exposure. When we expose for less than five minutes to a 1/200 solution (the death point) marked inhibition, but not death, of micro-organism is observed.

STREPTOCOCCUS EXPERIMENTS.

The tables in Group 5 show the experiments with streptococcus cultures.

is shown by one tube, while the others show death of organism. Therefore, it is evident that in the case of streptococcus pyogenes the sphere of inhibition is small because the relative points at which inhibition and death occur are almost identical.

BLASTOMYCOSIS EXPERIMENTS.

The experiments with blastomycosis cultures are detailed in Group 6.

CONSIDERATION OF EXPERIMENTS WITH BLASTOMYCOSIS.

1/1000 for *fifteen* minutes shows no effect.

1/1000 for *thirty* minutes shows no effect.

1/1000 for *sixty* minutes shows on the fourth day of real growth or second day of apparent growth a considerable inhibitory effect which, however, does not extend to the following day.

1/500 for *fifteen* minutes shows no growth.

1/500 for *ten*, *five*, and *four* minutes shows no growth.

1/500 for *three* minutes shows no growth on A, C, and D throughout. B is free from growth up to the fourth day of the actual growth or third day of real growth. At this point a very slight growth is noticed which increases very slowly to the tenth day, when it equals ¼ control growth.

1/500 for *two and one-half* minutes shows an inhibitory effect of markedly varying degree on the different tubes. C gives no growth throughout, D gives none up to the eighth day, when a unit of growth appears which increases progressively on the ninth and tenth days, equaling, on the tenth day, 1/3 control growth. A shows a marked inhibitory effect up to the seventh day, when it gives a rapid increase in growth. On the remaining days the experimental and control tubes are practically identical in growth. Likewise, B shows a marked inhibitory effect up to the fifth day, when experimental tube begins to increase rapidly, equaling control tube on the eighth, ninth and tenth days.

* In the exp. tubes the growth was extremely thin and film-like, showing in A, B, C and D microscopically, poorly staining small streptococci, in comparison with the controls.

CONSIDERATION OF EXPERIMENTS WITH STREPTOCOCCUS.

1/1000 for *fifteen* minutes shows an inhibitory effect. On the first day A, C, and D show points of growth, B 1/6 of control growth. On the second, third and fourth days there is a very slight, irregular increase in growth on experimental tubes. This growth equals about 1/6 control growth.

1/1000 for *thirty* minutes shows no growth.

1/500 for *ten* minutes shows no growth.

1/500 for *five*, *four*, *three*, and *two* minutes shows no growth.

1/500 for *one* minute exhibits marked inhibitory effect. A, B and D are free from growth throughout. On the second day C shows a fractional growth which increases rather rapidly on the third and fourth days, equaling 4/7 of the control growth at the end.

SUMMARY OF EVIDENCE ON STREPTOCOCCUS.

An exposure for two minutes to a 1/500 solution of iodin causes the death of *Streptococcus pyogenes*. The same result is obtained by using a 1/1000 solution for thirty minutes. A consideration of the inhibitory effect shows that this power is exhibited very markedly by a 1/1000 solution for fifteen minutes. Likewise, on exposing organism to a 1/500 solution for one minute, we find that an inhibitory power of medium degree

SUMMARY OF EVIDENCE ON BLASTOMYCOSIS.

Blastomyces is killed by an exposure of four minutes to a 1/500 solution of iodin. Here, more markedly than in preceding series, is the inhibitory effect of solutions employed shown to be of little consequence. In fact, in this series, it may be almost entirely disregarded, for it is shown only transitorily for one day by a 1/1000 solution for sixty minutes. In other words, there is practically no sphere of inhibition, the first effect shown being destruction of fungus. The exposures for three and two and one-half minutes simply bear out preceding statements, showing as they do either absolute death or markedly irregular inhibitory effect.

ACTINOMYCOSIS EXPERIMENTS.

The results of the experiments with cultures of actinomycosis are shown in the tables in Group 7.

CONSIDERATION OF EXPERIMENTS WITH ACTINOMYCOSIS.

1/1000 for *fifteen* minutes shows no inhibitory effect, especially on the second, third and fourth days. A and C are negative to the fifth day, when points appear. Likewise, on the *fifth* day B equals 3/7 control growth and D gives points. From the fifth day on A and C show no further development, B increases rapidly to 2/3 control growth, and D slowly to 1/6 control growth.

1/1000 for *thirty* minutes shows a marked inhibitory effect. On the second, third and fourth days there is no growth. On the fifth day points appear on A, C, and D, which, to the end, increase very slightly. On the fifth day points of growth appear on B, which, on the remaining days, increases slowly, equaling at the end 1/12 of control growth.

1/1000 for *sixty* minutes gives a marked inhibitory effect. On the second, third and fourth days there is no growth. A is free from growth throughout. On the fifth and sixth days points appear on B, C and D. On the following days B shows no increase in growth, C gives a few more points, and D, on the eighth and ninth days gives a fractional growth, equaling 1/10 control growth at the end.

1/500 for *fifteen* minutes gives no growth.

1/500 for *ten* minutes shows an irregular effect. A and C are free from growth throughout. On the third day points of growth appear on B and D, which increase slowly to the ninth day, when B equals 2/7 of control growth and D 1/12 control growth.

1/300 for *ten* minutes gives no growth.

1/300 for *five* minutes shows a marked inhibitory effect. B and C show no growth throughout. On the sixth day points of growth appear on A. On the following days a very slight increase in growth is present, equaling, at the end, 1/16 of control growth. On the fifth day points appear on D, which increase but slightly on the remaining days.

1/200 for *five* minutes shows no growth.

1/200 for *two* minutes shows no growth.

1/200 for *one* minute shows no growth.

SUMMARY OF EVIDENCE ON ACTINOMYCOSIS.

The evidence shows that *Actinomyces bovis* is destroyed by either of several strengths solution of iodin acting for varying periods of time. Thus, death occurs after an exposure to a 1/500 solution for fifteen minutes; to a 1/300 solution for ten minutes; to a 1/200 solution for one minute. Considering the inhibitive effect of the solutions on the micro-organism, we find that this power begins to appear quite perceptibly on exposing to a 1/1000 solution for fifteen minutes. This effect is increased in proportion as the time of exposure is lengthened. On exposing to solutions of greater strength for a shorter period than is necessary to cause death, i. e., 1/500 solution for ten minutes, 1/300 solution for five minutes, the inhibitory effect becomes, to a medium degree, greater and greater, although time of exposure is markedly decreased. Therefore, in this series, we may consider that iodin has a medium range of inhibition before causing death.

GENERAL SUMMARY.

In summing up the antimicrobic power possessed by iodin in solution, it is well for clearness to adhere to the two divisions previously made. These were: (1) The death point of the micro-organisms as expressed by the strength of solution employed and the time of exposure to same; (2) the inhibitory effect of solutions as expressed by retardation and limitation of growth. Taking for consideration the first division, the evidence shows that absolute destruction of the several micro-organisms occurs when they are exposed to the solutions as given in Table 92.

Micro-organism.	Strength of solution.	Time of exposure.
Streptococcus pyogenes	1/1000	30 minutes
	1/500	2 minutes
Blastomycosis	1/500	4 minutes
Actinomycosis bovis	1/500	15 minutes
	1/300	10 minutes
	1/200	1 minute
Staphylococcus pyogenes aureus.....	1/200	5 minutes
Bacillus tuberculosis	1/200	60 minutes
	1/100	7 minutes
Bacillus anthracis plus spores	1/200	60 minutes
	1/100	10 minutes
Bacillus prodigiosus	1/100	10 minutes

A considerable range in efficiency of solutions is shown to exist between the *Streptococcus pyogenes* and the *Bacillus prodigiosus*. On the *Streptococcus pyogenes* the effect of the iodin is almost, if not altogether, a specific. The same, to a lesser degree, may be said of its action on *Blastomyces*. As per the arrangement of the table, the *Staphylococcus pyogenes aureus* is seen to occupy, in its relation to resisting power, a middle position. In regard to this same power of resistance, a wide space intervenes between the *Staphlycoccus aureus* and the bacilli group, of which the non-pathogenic prodigiosus is the most hearty. However, the employment of the strongest solution necessary (1 per cent. for ten minutes) is eminently practicable in direct application to wound surfaces without bad effects resulting. The fact that a micro-organism is or is not pathogenic has no weight in determining its power of resistance.

Taking for consideration the second division, it is readily seen that the degree of inhibition depends both singly and jointly on the strength of solution employed and the duration of exposure to the same. This inhibitory cycle is well shown by the bacilli group where there is a gradual and progressive increase in the inhibitory power over a wide range as the solutions become stronger and stronger and the time of exposure is increased in each strength. On this group iodin has a marked range of inhibition before producing death. The inhibitory sphere in *Staphylococcus pyogenes aureus* is irregular in character and much smaller because of the lesser strength of solution causing death. Likewise, for the same cause, *Actinomyces* presents a still more restricted sphere, although steadily progressive in character. On both *Streptococcus pyogenes* and *Blastomyces* the range of inhibition is so minute, because the death and inhibitory points are practically the same, that it may be disregarded.

CONCLUSIONS.

1. In a solution of iodin, varying from a 0.2 per cent. to a 1 per cent., we have a germicidal agent of very marked potency.

2. Its germicidal power is far superior to that of bichlorid of mercury, the acknowledged leader of all other antiseptics. This fact was shown by experiments made with a 1/1000 solution of bichlorid of mercury on *Streptococcus pyogenes*, using the same method employed with iodin solution. It was found that an exposure of fifteen minutes, although showing considerable inhibitory power, especially on the first day, permitted a good growth of streptococci to appear. An exposure of thirty minutes gave no growth. The superiority of iodin is readily evidenced by recalling the fact that a comparatively weak solution of iodin, i. e., 0.2 per cent., gave death after two minutes' exposure.

3. It approaches nearly to the ideal antiseptic in that:

(a) It is easily prepared and is stable.

(b) It is non-toxic and non-irritating in strength effective, being only one-fourth as toxic as bichlorid of mercury.

(c) It does not coagulate albumin or form inert compounds with tissues.

(d) It is effective in a very brief time.

(e) The stain it produces soon disappears.

(f) Lastly, *and most important*, it possesses a remarkable penetrating power.

4. In conclusion, it is well to state that an 0.5 per cent. solution is amply strong enough for all practical usage.

THE UNITED STATES PHARMACOPEIA.

THE ADVANCE IN PHARMACY INDICATED IN THE EIGHTH DECENNIAL REVISION.*

C. S. N. HALLBERG, Ph. G., M.D.

CHICAGO.

The Pharmacopeia was made public June 27, when unbound copies of the book were sent to medical and pharmaceutical journals, medical publishers, authors, and such other persons to whom avoidance of the two weeks' delay in securing bound copies of the volume would be especially appreciated.

THE NOMENCLATURE.

The Pharmacopeia, as the exponent of the science of drugs and medicine, must employ a terminology in harmony with the related sciences, hence the importance of the nomenclature. With reference to the nomenclature the convention adopted the following among the general principles to be followed in revising the Pharmacopeia:

> It is recommended that changes in the titles of articles at present official be made only for the purpose of insuring greater accuracy or safety in dispensing. In the case of newly admitted articles it is recommended that such titles be chosen as are in harmony with general usage and convenient for prescrib-

---

* Read in the Section on Pharmacology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

ing; but in the case of chemicals of a definite composition a scientific name should be given, at least a synonym.

It is recommended that every common name and English title of articles used in the present United States Pharmacopeia that is synonymous for both the medicinal and commercial drug be either discarded or modified so as to leave no doubt as to what is wanted.

With reference to the chemical nomenclature, that of the former revision has been retained notwithstanding the fact that the spelling adopted by the American Association for the Advancement of Science and chemical societies has met with some degree of favor. The deletion of the final *e* in the halogens and alkaloids, such as "bromine," "iodine" and "morphine" and "quinine," respectively, it was thought, would prove confusing; besides, the alkaloids would lose the distinction they have always enjoyed in being written with the final *e*, from the glucosids without it, i. e., aloin, santonin, etc. So also was the substitution of *f* for ph in the case of sulphur and sulphates (sulfates), regarded probably as too much of an innovation, especially when the spelling of "Pharmacopœia" was considered. The spirit of conservatism was so evident that the convention refused even to eliminate the *o* in the spelling of "Pharmacopœia," although the British is the only other Pharmacopeia which retains this ancient spelling.

Another innovation was narrowly averted when the figures for the elements of the International Committee on Atomic Weights of 1904 were adopted, based on hydrogen at 1 instead of oxygen at 16, which would have made H 1.008. The fear of innovation did not deter the committee, however, from making some timely corrections in chemical terms, such as changing the official titles for three well-known acids: carbolic, arsenous and chromic to phenol, arseni-trioxidum and chromi-trioxidum respectively; resorcinol for resorcin, potassii hydroxidum for potassa, sodii hydroxidum for soda, the *id* termination for salts of alkaloids, i. e.: cocainæ hydrochloridum for cocainæ hydrochloras, the contracted term "fluidextractum" for extractum-fluidum, and the less doubtful substitution of chloralum hydratum for chloral as being liable to confusion with chlor. hydr., when carelessly abbreviated.

PURITY AND STRENGTH OF PHARMACOPEIAL ARTICLES.

The limitations on the purity and strength of pharmacopeial articles have received much consideration, especially during the past decade, because of the extreme requirements, in some instances characterized as hypercritical by manufacturers. Having in mind, no doubt, the greatest protection to the public, the convention gave the following instruction:

The committee is instructed to revise as carefully as possible the limits of purity and strength of the pharmacopeial chemicals and preparations for which limiting tests are given. While no concession should be made toward a diminution of medicinal value, allowance should be made for unavoidable, innocuous impurities or variations due to the particular source or mode of preparation, or to the keeping qualities of the several articles. In the case of natural products, the limits of admissible impurities should be placed high enough to exclude any that would not be accepted by other countries.

To the present revision, therefore, has been added a descriptive definition for each chemical known as the "purity rubric," which defines and limits the gross amount of impurities in each article by stating, for example, potassii iodidum: "It should contain not less than 99 per cent. of pure potassium iodide (KI=164.76)."

To make this article 100 per cent. pure would not only add vastly to the cost but in this particular salt would result in a product which would be stable. In the elaborate tests which follow, the amounts of alkali, nitrates and nitrites, chlorids and bromids are carefully limited within the total one per cent. permissible, while they absolutely exclude all noxious salts, such as barium, cyanid and heavy metals, lead, tin, zinc, etc. By this method, the highest practically attainable degree of purity is secured with the certainty that all noxious impurities are absent.

ASSAY PROCESS.

The standardization of drugs and their preparations also for certain principles has long been a desideratum. The medical profession has especially favored this idea because it represented an apparently decided advance in therapeutics. It was also in line with the entire spirit of the Pharmacopeia, and the ideals of pharmacy, viz.: to secure uniformity in strength and dosage. Its application, however, was an entirely different and much more difficult proposition than fixing the uniformity of chemical substances from the fact that the principles of but comparatively few drugs are as well defined as ordinary chemical substances, and their identity and determination, therefore, require much more careful and elaborate study. For this reason the committee was instructed:

The committee is instructed to append assay processes to as many of the potent drugs and preparations made therefrom as may be found possible, provided that the processes of assay are reasonably simple (both as to methods and apparatus required) and lead to fairly uniform results in different hands. As regards the products of such assays, tests of identity and purity should be added wherever feasible. Physiologic tests for determining strength should not be introduced by the committee.

After exhaustive study by a committee of specialists, some of whom have been engaged with the various large manufacturing pharmaceutical houses, assay processes were introduced for eighteen drugs and their preparations, and the following standards have been adopted for them:

Drugs and their preparations for which standards of active principles are required by the U. S. P. VIII.

Preparation.	Principle.	Minimum.
Aconitum	Aconitin	0.5 per cent.

The introduction of several principles of volatile oils, some artificial or synthetized, led to the fixing of standards for a number of the natural volatile oils, which are required to be of the following strengths:

Oil.	Principle.	Strength.
Oleum amygdalæ amaræ	Benzaldehyd	85 per cent. w't.
	Hydrocyanic acid	2.4 per cent. w't.
Oleum cajupti	Cineol	55 per cent. vol.
Oleum caryophilli	Eugenol	80 per cent. vol.
Oleum cinnamomi	Cinnamic aldehyd	75 per cent. vol.
Oleum eucalypti	Cineol	50 per cent. vol.
Oleum limonis	Citral	4 per cent. w't.
Oleum menthæ piperitæ	Menthyl acetate	8 per cent. w't.
	Total menthol	50 per cent. w't.
Oleum		65 per cent. vol.
Oleum		5 per cent. w't.
		15 per cent. w't.
Oleum santali	Santalol	90 per cent. w't.
Oleum thymi	Phenols	20 per cent. vol.

In addition to this class of principles, already official menthol, thymol and methyl salicylate, the following have also been introduced:

Benzaldehydum: An aldehyd obtained from the volatile oil of bitter almond or produced artificially, containing 85 per cent. pure benzaldehyd.

Cinnaldehydum: An aldehyd obtained from oil of cinnamon or prepared synthetically, containing not less than 95 per cent. pure cinnamic aldehyd.

Eugenol: An unsaturated aromatic phenol obtained from oil of cloves and other sources.

Safrolum: The methylene ether of pyrocatechol, found in oil of sassafras, camphor oil and other volatile oils.

The difficulty presented in work of this branch of organic chemistry may be realized from the fact that of these eighteen drugs not one glucosidal drug is included, they being, with one exception, (jalap) alkaloidal. While to devise assay processes which would be practicable and which, in the hands of the average skilled pharmacist, would show fairly uniform results, was exceedingly difficult with some of these, notably the mydriatic group, with glucosidal drugs these difficulties were unsurmountable. For this reason, there are no assay processes nor standards for the principles of digitalis, ergot, strophanthus and several more of this class, much as it was desired to include them. By far the largest number of drugs are glucosidal in character and yet, with a few exceptions, they are but little known. There are many drugs indigenous to North America, not to mention Central and South America, whose principles, if studied systematically, would furnish valuable therapeutic agents, perhaps equally as valuable as the coal-tar and other synthetic chemicals. This field may well be called a *terra incognita* which lies fallow for a medical Vespuccio or Vasco de Gama, but more likely which will be chartered and explored by the *omnium gatherum* Teutons when they have exhausted the possimilities of the Benzene ring and its congeners.

Owing to the lack of chemical assay methods for standardizing some of these drugs, certain manufacturers have adopted so-called physiologic methods for determining the strength and potency. Since no method based on pharmaco-dynamic effects could be applied by the average retail pharmacist for whom the U. S. Pharmacopeia is, first of all, designed, and since any requirement for an article which could not be verified by him would, it was contended, violate this fundamental principle of the Pharmacopeia, it was recommended "that physiologic tests should not be introduced."

Owing to the importance of the subject, however, and with the aid of a special committee composed of Major Walter Reed, surgeon U. S. A., Prof. Theobald Smith, Thomas C. Craig, surgeon U. S. A., H. A. Hare, E. M. Houghton, J. J. Kinyoun, William H. Park, Herbert D. Pease, and M. J. Rosenau, surgeon U. S. Public Health and Marine-Hospital Service, the following standard was adopted:

Serum Antidiphthericum—Antidiphtheric serum. Diphtheria antitoxin.

A fluid separated from the coagulated blood of a horse Equus caballus (Linnè), immunized through the inoculation of diphtheria toxin. It should be kept in sealed glass containers, in a dark place, at temperatures between 4.5 and 15 C. (40 and 59 F.).

A yellowish or yellowish brown, transparent or slightly turbid liquid, odorless or having a slight odor, due to the presence of the antiseptic used as a preservative.

Specific gravity: 1.025 to 1.040 at 25 C. (77 F.).

Antidiphtheric serum gradually loses its power, the loss in one year varying between 10 and 30 per cent. Each container should be furnished with a label or statement, giving the strength of the antidiphtheric serum, expressed in antitoxic units, the name and percentage by volume of the antiseptic used for the preservation of the liquid (if such be used), the date when the antidiphtheric serum was last tested, and the date beyond which it will not have the strength, indicated on the label or statement.

The standard of strength expressed in units of antitoxic power should be that approved or established by the United States Public Health and Marine-Hospital Service.

Average dose, 3,000 units.

Immunizing dose for well persons, 500 units.

The admission of the synthetics, owing to the complex status of many of them, was a difficult problem to solve. The attitude of the convention was not sharply outlined in the following instruction to the committee:

The Committee of Revision is authorized to admit into the Pharmacopeia any product of nature of known origin, also any synthethized product of definite composition which is in common use by the medical profession, the identity, purity or strength of which can be determined. No compound or mixture shall be introduced if the composition or mode of manufacture thereof be kept secret, or if it be controlled by unlimited proprietary or patent rights.

Realizing the desire on the part of the medical profession to have, at least, made official as many of this class of articles as have proved of therapeutic value and have assumed a permanent place in the materia medica, the committee compromised by admitting such products for which the patent on the process or product, or both, expired or will expire during the present decade (1910), provided that, by such expiration, the trade name would also become free.

With this as a guide, the legal status of the most extensively employed synthetics was investigated, and those which would be free during the stated period were admitted. Some omissions will be noted, for example, ichthyol, which is not covered by any patent, the name alone being registered, and the article, therefore, is in the category of so-called patent medicines, except that its composition is well known.

Except in the case of antipyrin, which became free several years ago, the trade names of these articles have not been admitted, but instead more or less euphonious contractions of the chemical names have been adopted for their title, together with the chemical structural names, as follows:

Acetphenetidium—Acetphenetidin: $C_{10}H_{13}NO_2 = 177.79$.

A phenol derivative [Acetparaphenetidin $C_6H_4(OC_7H_5).NH.CH_3.CO$1:4] the product of the acetylization of para-amido phenol.

Average dose, 0.500 gm., 500 milligrams (7½ grains).

Æthylis Carbamas—Ethyl Carbamate: $C_3H_7NO_2 = 88.42$.

An ester of carbamic acid [$CO(OC_2H_6)NH_2$] obtained by the reaction of ethyl *alcohol on urea* (carbamide) or one of its salts. It should be kept in well-stoppered bottles.

Average dose,, 1 gm. (15 grains).

Antipyrina—Antipyrin: $C_{11}H_{12}N_2O = 186.75$.

Phenyldimethylpyrazolon [$C_3HN_2O(CH_3)_2.C_6H_5$], obtained by the condensation of phenylhydrazin with aceto-acetic ether, and methylation of the product.

Average dose, 0.25 gm., 250 milligrams (4 grains).

Benzosulphinidum—Benzosulphinid Saccharin.

$$C_6H_4 \left\langle \begin{matrix} SO_2 \\ CO \end{matrix} \right\rangle NH = 181.77$$

The anhydrid of ortho-sulphamide-benzoic acid (benzoyl sulphonicimide).

Average dose, 0.200 gm., 200 milligrams (3 grains).

Chloralformamidum—Chloralformamid: $C_3H_4Cl_3NO_2 = 190.96$.

A crystalline solid [$CCl_3.CH(OH)NH.COH$], made by the direct union of formamide with anhydrous chloral. It should be kept in amber-colored, well-stoppered vials.

Average dose, 1 gm. (15 grains).

Guaiacolis Carbonas—Guaiacol Carbonate: $(C_7H_7O)_2CO_3 = 272.05$.

A guaiacol derivative [$(C_6H_4(OCH_3)O)_2.CO$], obtained by the action of carbonyl chlorid on sodium-guaiacolate.

Average dose, 1 gm. (15 grains).

Hexamethylenamina—Hexamethylenamin: $C_6H_{12}N_4 = 139.18$.

A condensation product [hexamethylene-tetramin, $(CH_2)_6N_4$], obtained by the action of ammonia on formaldehyd. It should be kept in well-stoppered bottles.

Average dose, 0.250 gm., 250 milligrams (4 grains).

Homatropinæ Hydrobromidum—Homatropin hydrobromid: $C_{16}H_{21}NO_3.HBr = 353.49$.

The hydrobromid [$HBr.C_{16}H_{21}NO_3$] of an aklaloid obtained by the condensation of tropin and mandelic acid. It should be kept in well-stopered vials, protected from light.

Average dose, 0.0005 gm., 0.5 milligram (1/128 grain).

Iodolum—Iodol: $C_4I_4.NH = 566.17$.

Tetraiodopyrrol, a derivative of the base pyrrol, obtained by the direct action of iodin on the base in the presence of alcohol. Iodol should be preserved in amber-colored bottle, protected from light.

Average dose, 0.250 gm., 250 milligrams (4 grains).

Methylthioninæ Hydrochloridum—Methylthionin Hydrochlorid. Methylen Blue: $C_{16}H_{18}N_3SCl = 317.36$.

Tetramethylthionin hydrochlorid, obtained by the action of hydrogen sulphid on an oxidation product of paramidodimethylanilin.

Average dose, 0.250 gm., 250 milligrams (4 grains).

Sulphonethylmethanum—Sulphonethylmethane: $C_8H_{18}S_2O_4 = 240.46$.

Di-ethyl-sulphone-methyl-ethyl-methane [$(CH_3)(C_2H_5)C(SO_2C_2H_5)_2$], a product of the oxidation of the mercaptol obtained by the condensation of methylethylketone with ethyl mercaptan. It should be preserved in well-stoppered vials.

Average dose, 1 gm. (15 grains).

Sulphonmethanum — Sulphonmethane: $C_7H_{16}S_2O_4 = 226.55$.

Diethylsulphonedimethylmethane [$(CH_3)_2C(SO_2C_2H_5)_2$], the product of the oxidation of the mercaptol obtained by the condensation of acetone with ethylmercaptan. It should be preserved in well-stoppered vials.

Average dose, 1 gm. (15 grains).

Thymolis Iodidum—Thymol Iodid: $C_{20}H_{24}O_2I_2 = 545.76$.

Dithymol-diiodid [$(C_6H_2.CH_3.C_3H_7.OI)_2$], obtained by the condensation of two molecules of thymol and the introduction of two atoms of iodin into the phenolic groups of thymol; it contains 45 per cent. of iodin. Thymol iodid should be kept in amber-colored vials, protected from the light.

Vanillinum—Vanillin: $C_8H_8O_3 = 150.92$.

Methylprotocatechuic aldehyd [$C_6H_3OH.OCH_3COH$ 4:3:1], occurring naturally in vanilla or made artificially from several orthodihydroxybenzene derivatives.

Average dose, 0.030 gm., *30 milligrams* (½ grain).

IMMUNITY.

CHAPTER XXIV.

BACILLUS ENTERITIDIS IN MEAT POISONING.

More or less extensive epidemics of poisoning by meats have long been known. Whereas, it was formerly thought that the intoxication was due to ptomains which were formed as an incident to putrid decomposition of meat, it is now well established that most epidemics of this character are caused by meats which are infected with bacteria which are pathogenic even when entirely freed from decomposing proteids.

The "Enteritidis Group."

Botulism has already been described as a special form of meat poisoning in which nervous symptoms predominate, and it has also been emphasized that paratyphoid fever may have its source in infected meat. Before these conditions were recognized, however, Gärtner in 1888 had the opportunity of studying an epidemic caused by the meat of a cow which had been slaughtered in extremity. The symptoms differed from those of botulism or paratyphoid, as described below. He obtained *from the muscle and spleen of* the cow, and from the spleen of a man who had been fatally poisoned by meat, an organism which has since been known as *Bacillus enteritidis* (Gärtner). The same bacillus, or organisms which resemble it closely, have been obtained repeatedly during similar epidemics, both from the suspected meat and from the organs in fatal cases (intestines, blood, spleen, etc.). Drigalski, from a comparative study of several strains which had been obtained from different sources, concluded that all are members of a closely related group of organisms, the group of *Bacillus enteritidis*. His conclusions were based on cultural properties and agglutination tests.

The typical organism is a short rod, often ovoid in shape; it possesses four to twelve long flagellæ and has moderate motility. It is not stained by Gram's method. It ferments dextrose and certain other sugars, lactose, galactose, maltose, cane sugars, etc., with gas formation. Variations among individual strains need not be discussed here.

Pathogenicity.

According to v. Ermengem, and also Drigalski, the pathogenicity of the organism depends on its elaboration of a soluble but heat resistant toxin. Bouillon cultures twelve days old, in which the bacteria have been killed by heat, also similar cultures from which the bacteria have been removed by filtration, are toxic for mice and guinea-pigs (Drigalski). It is noteworthy, however, that relatively large quantities of the bouillon were *necessary to kill* guinea-pigs (4.0 c.c.), which is in contrast to the toxins of diphtheria and tetanus. The rapidity with which symptoms develop following the ingestion of infected meat is a further indication of the existence of this soluble toxin.

Symptoms.

Symptoms occasionally develop so quickly as to suggest some strong metallic poisoning. Within a few hours vomiting, violent diarrhea and colicky pains set in, followed by more or less collapse, weakness, headache and not uncommonly by trythematous, urticarial or herpetic eruptions. Fever is absent or inconspicuous. The mortality is not high, from 2 to 5 per cent., although convalescence is said to be slow. Nephritis and catarrhal pneumonia have been noted as sequelæ. Autopsy shows the anatomic changes of an acute gastroenteritis, sometimes of hemorrhagic character, with swollen Peyer's patches; the large intestine is not greatly involved. The spleen may be swollen and the kidneys degenerated. The anatomic findings are not specific.

Source of Infection.

It has been shown conclusively in numerous instances that the meat infection takes place *intra vitam*, that is, that the cattle or horses (Drigalski) were sick with an intestinal or general infection with *Bacillus enteritidis* before they were slaughtered. "In a very large number of cases it can be demonstrated that the animals from which the meat was taken had been slaughtered in extremity and had died rapidly, and indeed, that they had (in certain instances), died before they could be slaughtered. Most often they suffer from septic inflammatory processes or from traumatic, puerperal or other sorts of septicemia, or from other ill defined pathologic conditions which are accompanied by symptoms of enteritis or intestinal or pulmonary inflammations." (v. Ermengem.) Subsequent infection of the meat by *Bacillus enteritidis*, i. e., after slaughtering, has not been noted.

Growth in the Meat.

The organism occurs in the blood, muscles, spleen, lungs, and probably in the other organs of the infected animals and of man. Poisoning most commonly arises when the meat has been kept for several days, which usually is the case by the time it is made into some form of sausage. In the meantime the bacilli have proliferated and additional toxin has been produced. In at least one instance a certain number of patients who ate the meat while it was fresh suffered moderate or no intoxication, whereas those who ate it several days later became violently ill. In an epidemic caused by horse meat Drigalski found that "only those persons suffered from intoxication who ate the meat after it had lain for eight days or more."

Toxin in Meat.

The micro-organism is very resistant to heat and the temperature which is attained in ordinary cooking may not be sufficient to kill all the bacteria which are the farthest from the surface. Even in the event that the meat has been thoroughly sterilized, the heat resistant toxin may be present in sufficient quantity to cause the intoxication. Not much is known concerning the distribution of *Bacillus enteritidis*. v. Ermengem suspects that it may be a cause of poisoning by oysters and fish, but this remains undetermined.

Agglutinins.

The blood acquires specific agglutinins during the course of infection. Even eight days after the beginning of symptoms agglutination may be obtained in dilutions varying from 1/200 to 1/4000. The agglutinins disappear very rapidly. Working with artificially prepared immune serum, Drigalski determined the existence of coagglutinins for typhoid and paratyphoid bacilli.

We should bear in mind the likelihood that meats poisoned with *Bacillus enteritidis*, as well as by paratyphoid bacilli, may be encountered in America as well as in foreign countries.

BACILLUS COLI COMMUNIS.

Bacillus coli communis, *Bacterium coli commune*, or the colon bacillus, is the type of a large group of organisms the members of which show individual differences but possess certain dominant features in common. The typical colon bacillus ferments various sugars, with the production of gas, is a strong acid producer and curdles milk. It is flagellated, has moderate motility and does not stain by Gram's method. One type or another is the normal inhabitant of the intestinal tract of many animals, and although the organisms are widely disseminated in nature their occurrence is related directly or indirectly to the distribution of feces.

Resistance.

Its optimum temperature for growth is 37 C., and above 46 C. it does not proliferate. It is killed at a temperature of from 60 to 61 C. in from five to fifteen minutes; it is not killed by such low temperatures as from 20 to 24 C. It resists absolute desiccation for periods varying from a few days to several months (different observers). Direct sunlight kills 99 per cent. of the germs in two hours (Billings and Peckham), and they are very susceptible to ordinary antiseptics. The normal serums of many animals are bactericidal for the colon bacillus.

Escherich, a noted authority on this organism, lays down the principle that that strain which may be cultivated from the feces of the nursing child should be considered as the typical *Bacterium coli commune*, maintaining that a constant type of organism is found under these conditions. It is said to occur here in relatively pure culture.

Distribution in the Intestines.

Within a very short time after birth the organism is found in the intestines of infants, and its method of entrance has been the subject of much discussion. In view of its wide distribution it is not difficult to conceive of many circumstances which favor its entrance. Having once reached the intestines, it finds there its optimum conditions for growth. The small intestines in man are rather free from colon bacilli and other organisms as well. This, perhaps, is due to some extent to the alkalinity of the medium and to the rather rapid flow of the intestinal contents. The colon bacillus reaches its maximum development in the large intestine, where, in fact, the whole bacterial flora of the intestines is most concentrated.

Normal Functions.

In view of the fact that the colon bacillus is a normal inhabitant of the intestines, the conception has occurred to many that it may be of distinct value to the economy, either because of the action it has on certain foods (splitting of carbohydrates), or because in some obscure way it influences favorably the assimilation of foods, or in that it antagonizes other bacteria of distinct pathogenic powers which also exist normally in the intestines or reach them through accident. This is not the place to consider these questions in detail, and they are on none too definite a basis. It may be stated, however, that the colon bacillus and another closely related organism, *Bacillus lactis aerogenes*, distinctly antagonize the action of certain proteolytic bacteria which appear to be associated with the putrid decomposition of milk and other proteid-containing foods. Bacteria of the later type exist in the intestines. Unsterilized milk has a natural resistance to putrid decomposition and sterilized milk, which contains the colon bacillus or *Bacillus lactis aerogenes*, has a similar resistance. These two bacteria flourish in the presence of carbohydrates, which they decompose with the liberal formation of acids, and through these acids they "limit intestinal putrefaction and influence (favorably) pathologic processes which are caused or maintained by the existing 'alkaline fermentation'" (Escherich and Pfaundler). That the organisms in question antagonize the action of putrefactive bacteria has been shown in test-tube experiments (Hirschler).

Pathogenicity.

Since the time that Emmerich upheld the colon bacillus (or a colon-like microbe) as the cause of Asiatic cholera (1885), opinion as to the pathogenic powers of the organism have undergone many fluctuations. Following Koch's demonstration of the vibrio of cholera as the etiologic factor in cholera, the colon bacillus was, so to say, repressed as a pathologic agent. Later, and especially in France, great significance was again attached to it. The condition still shows a great deal of chaos, although on account of more refined technic and the elimination of other organisms, as the dysentery and paratyphoid bacilli and *Bacillus enteritidis*, from the colon group proper, we are, perhaps, on the way to a more satisfactory understanding of the pathogenicity of this organism. Although certain authors hold at the present time that the colon bacilli which normally inhabit the intestines are devoid of virulence, such a radical position is open to question. Avirulent strains have often been encountered, however.

Virulence for Animals.

As harmless as the colon bacillus appears to be when confined in the intact intestines, its virulence for animals, although low, has been demonstrated in many instances. A bouillon culture of the average bacillus which has grown from one to two days, and when freshly cultivated from the stools, causes the death of a 300 to 400 gram guinea-pig in two or three days, when given intraperitoneally in a dose of from 2 to 3 c.c. Subcutaneous inoculations commonly cause abscesses and may lead to death. Pathologic processes have not been set up by feeding cultures to animals. Inflammations have been caused in the bladder and in the bile passages by the injection of cultures. It is stated (Escherich) that whether the cultures are introduced into the skin, peritoneum or vessels, the symptoms of severe gastroenteritis are produced, not unlike Asiatic cholera. This fact may have influenced Emmerich in considering the orgainsm as the cause of cholera. The general symptoms are those of an acute febrile intoxication.

The organism is most pathogenic when freshly cultivated, and soon loses its virulence after repeated transplantations. As in the case of some other organisms, virulence may be reestablished by "passage" through suitable animals.

Virulence for Man.

The cultivation of the colon bacillus from the blood and organs of man at autopsy has not the significance which was once attached to it. It has been recognized that the colon bacillus in particular, and less commonly other intestinal organisms, may enter the circulation a short time before death, at a time when resistance is very low, and may obtain the general distribution which is so often encountered at autopsy; this is the so-called "agonal invasion," which may occur without much regard to the primary cause of death. The conditions which favor agonal invasion remain to a large extent obscure. Distinct defects of the intestinal mucosa probably are not essential, although this view has its representatives. In states of low vitality in which resistance to infection is decreased (disappearance of complement!), the organisms find conditions favorable to proliferation when they have once reached the circulation. In spite of the low virulence of the colon bacillus it commonly has a certain amount of toxicity and it may often be of significance even as an agonal infection.

Postmortem invasion of adjacent structures, as the gall bladder and liver through the biliary passages, and of the peritoneum through the intestinal wall, also occurs.

True Infections.

It has been shown that the colon bacillus occasionally causes the following conditions: Suppurative cholecystitis which may extend to the liver, peritonitis, septicemia, meningitis, cystitis, pyelitis and ascending suppurative nephritis, and abscesses in various organs, including suppurative processes in the middle ear. In one or more instances it has been thought that it caused vegetative endocarditis. Probably colon infections of the gall bladder do not occur in the absence of biliary stasis. Ordinarily cases of peritonitis in which the colon bacillus is encountered also show the presence of other pathogenic organisms, as streptococci or staphylococci; this is always the case in perforation peritonitis. Doubtless wrong conclusions have been drawn in many instances from the fact that the colon bacillus readily overgrows many other bacteria in ordinary culture media.

Cystitis.

Escherich attributes great importance to this organism as the cause of cystitis, especially in children, and states that it is probably the most common cause in all cases of cystitis. In 58 of 60 cases of cystitis in children the colon bacillus was found either alone or in mixed cultures. He also considers it the most common cause of pyelitis and ascending suppurative nephritis. An increased agglutinating power of the patient's serum for the organism cultivated from the urine is noted in these cases.

Diarrheas.

Great interest attaches to the colon bacillus in relation to enterocolitis and dysenteric diseases. Escherich speaks of an *enteritis follicularis*, or *colitis contagiosa*, or colicolitis, epidemics of which have been noted at different times. A number of these epidemics occurred before the identification of the dysentery bacillus, and certain of them may have been true dysenteric infections. Nevertheless, dysentery bacilli are not found in all cases of enterocolitis, and the probability that genuine cases of colon enteritis occur can not as yet be neglected entirely.

A specific colon toxin has not been obtained.

Immunization with the colon bacillus causes the formation of bactericidal amboceptors and agglutinins.

Agglutination.

Not all strains of the colon bacillus are identical in their agglutinogenic receptors. A serum which agglutinates one colon strain does not necessarily agglutinate all strains. The reaction, according to Paltauf and others, is largely an individual one. The serum of a patient who is suffering from a colon infection will agglutinate the particular strain causing the disease, but may not affect other strains. Hence, for diagnostic purposes, the test must be performed with the culture which has been obtained from the patient. Pfaundler says in reference to colicolitis that if other colon infections can be excluded, and if the serum of the patient gives the agglutination reaction in a dilution of 1 to 50 with the bacillus which has been cultivated from the stools, colon infection is indicated (Paltauf).

FOURTH OF JULY INJURIES AND TETANUS.

For the third consecutive year The Journal publishes statistics regarding injuries received during the Fourth of July celebration, with special reference to tetanus resulting from these injuries. The total number of cases this year is 104, surprisingly near to the number of cases in 1904, which was 105. In 1903 there were 415 cases. It is interesting likewise to compare the totals of accidents resulting from blank cartridges in the same years, which are in a like proportion. In 1903 there were 1,672 injuries from blank cartridges; in 1904, 1,005, and this year, 809. Regarding totals of accidents and their causes, we shall have further comment later in this paper.

The figures this year are from the same source as heretofore and treated in the same manner, so that any comparisons between the figures of this and either of the preceding years may be on a presumably like basis. The list of tetanus cases is as follows:

Tetanus cases occurred in 23 different states, or in 2 more than last year, but in 7 less than in 1903. The eight states having the highest number of cases are Illinois 20, Wisconsin 13, Pennsylvania 12, Michigan 9, Massachusetts 7, New York 6, Ohio 5, and California 4. Six states had 3 cases each, one state had 2, and eight states had 1 each. Wisconsin had more cases this year than in either of the previous years. Connecticut, Illinois, Iowa, Massachusetts and Michigan show an increase over last year. Illinois had 5 more cases than last year. Table 2 shows a comparison of the number of cases in each state for the three years.

Total	415	105	104
No states having cases	30	21	23

It appears that most of the restrictions by city ordinances against fireworks during the past few years have been against the toy pistol. This probably accounts for the decrease in the number of cases from this cause the last year and possibly for the enormous decrease from 1903. Table 3 shows a comparison between the causes of tetanus cases this year and the two previous years.

TABLE 3.—CAUSES OF TETANUS CASES.

	Blank cartridge.	Giant cracker.	Cannon.	Firearms.	Powder, etc.
1905	65	17	4	5	13
1904	74	18	5	1	7
1903	363	17	5	3	27

While the number of cases from blank cartridges is decreasing each year, cases from the other causes remain about the same or on the increase.

Besides the lockjaw cases directly due to 4th of July accidents, 32 cases were reported this year due to other injuries, as penetrating wounds from nails, splinters, from crushing injuries in falls or otherwise, compared with 55 such cases last year and 15 in 1903.

DEATHS AND INJURIES ASIDE FROM TETANUS.

In Table 4 will be found a summary of all injuries, including tetanus, as well as of all causes. This is arranged, as heretofore, by states, so that comparisons may be made. Beneath the totals at the bottom of this table we have inserted for comparison the totals for 1903 and 1904. Table 5 is arranged to show a more ready comparison by states of the total accidents and deaths for three years.

Pennsylvania, the birthplace of independence, is this year, as last, far in the lead with 721 casualties, followed by New York with 566 and Illinois with 542. Two years ago Massachusetts led with 637, but last year dropped to eighth place with only 193, and returned this year to fourth place with 467. The 1,007 total increase over last year is fairly well distributed among the states.

All accidents were carefully omitted which were *not* received in the discharge or handling of fireworks or other means of noise production on or about the Fourth of July. For instance, some soldiers in the course of their regular duty were killed by the explosion of a cannon while firing the morning salute on the morning of the Fourth. As this might have happened at any time and was in line with their regular duty, it could not well be considered as due to fireworks for Fourth of July celebration.

Besides 87 deaths from tetanus, there were 95 from other accidents, making a total of 182 deaths. There were 4,994 non-fatal injuries, or over a thousand more than the total for last year, which was 3,986, or for 1903, which was 3,983. Therefore, the total of dead and injured was 5,176, as compared with 4,169 for last year, or 4,449 for 1903. Yet for all this enormous number of injuries we find some cities congratulating themselves on the small number of accidents this year! Some of these reports are rather pathetic. After the expression regarding the "comparatively few accidents this year" follows a long list of names of those having eyes put out, fingers or hands torn off, of one young man to save whose life it was necessary to amputate both legs, and of others having their faces lacerated or other disfigurements which the hapless celebrants will carry with them to the ends of their lives. And this was "better than former years!"

Of the 95 killed, aside from tetanus, through the use of fireworks, there were 37 persons killed by gunshot wounds, 13 of these being hit by stray bullets from the reckless use of loaded revolvers or rifles on the part of others; 23 persons, mostly young children, were burned to death by fire resulting from fireworks; 10 persons died from fright or shock as a result of the sudden loud noises near them. A baby was thrown into convulsions and died as the result of a large firecracker explosion near its ear; 7 were killed by a cannon, a number by the bursting of these from an overcharge of powder; 4 were killed by giant crackers, 4 by powder explosions, 3 by misdirected sky rockets, 2 by falls in efforts to get away from firecrackers, 2 in runaways due to firecrackers being thrown beneath the horses, 2 by dynamite and 1 by the explosion of a railroad torpedo.

† Figures for accidents caused by stray bullets included with "gunshot" wounds in 1903 and 1904.
‡ Figures for accidents caused by canes and caps included with "powder and fireworks" in 1903 and 1904.

The non-fatal accidents were apparently more severe this year than last, 6 more were made totally blind, 45 more lost one eye, 19 more lost a leg, arm or hand, and 13 more lost one or more fingers. The most prolific source of severe accidents, causing blindness, loss of hand, arm or other lacerated wounds was the giant cracker. Almost invariably the injury resulted from the picking up of the cracker or retaining it in the hand on the supposition that "it had gone." From a number of sources comes the observation that, while the spark continued to burn the central pith, *the outer part of the fuse ceased to burn.* Thus the spark had disappeared, giving the impression that it had gone out until an explosion resulting in the tearing or loss of an eye, finger, hand or arm, gave ample proof to the contrary. This is further shown by the experience of one lad who picked up the cracker and put it under water to make sure the spark was out, but still it exploded, tearing his hand badly.

Following the giant cracker, the toy cannon still nearly holds its old place as a means of destruction. Stray bullets are entered in a column by themselves where heretofore they were entered in the column with "gunshot" wounds. This will show how many people are injured through the careless use of firearms on the part of others, and show in what states laws against firearms are less strictly enforced. As before stated, 13 people were killed outright through this recklessness, and 126 others more or less seriously injured.

We have added a column for the canes and caps. Even these canes, which at first were heralded as a safe means of noise making, are not as harmless as at first supposed. The noise element is certainly a success, but the exploding cap often causes penetrating wounds of the ankles or legs—usually the most unprotected part of those who use them, the boys with knee pants. Then, overcharging the cane caused it to explode in many instances, the particles of iron doing considerable damage. One case of tetanus this year resulted from such an injury.

As to preventative measures, we learn from many sources that great pains were taken this year to be prepared *to give antitoxin in all injuries of a penetrating nature.* Health departments in some of our large cities distributed a supply of antitoxin to the various hospitals and dispensaries that it might be ready if needed. Local medical organizations met before the Fourth, discussed the treatment of tetanus, and passed resolutions in favor of legislation regulating or restricting the use of fireworks. Cities passed ordinances, some only against the toy pistol, others prohibiting the sale of firecrackers above a certain size. Others prohibited the use of fireworks on any other day than the Fourth, while one city, Baltimore, placed the ban on the use of fireworks of all descriptions. The results in Baltimore are certainly gratifying, there being only 6 accidents reported from that city, and these of a minor nature.

This year, however, many cities did not stop with the passing of ordinances; arrests for their violation were numerous, and therein is a hopeful sign. Only a few years ago an arrest for making a noise on the anniversary of the nation's independence would have been looked on as against the spirit of patriotism and declared an outrage. Nothing better shows the change in public sentiment than the fact that this year a great many arrests were made and by public approval. Undoubtedly the publication of the facts, showing the enormous cost in life and limb of this manner of celebrating the Fourth of July, has helped to bring about this change in sentiment. The vigorous action of medical organizations throughout the land has added impetus, and the press has taken the matter up to a remarkable degree and has made good use of our published data on the subject.

The work should go on, however, until properly enforced laws shall put an end to the annual slaughter and maiming of so many of our children and young people. It is certainly high time there was an end to it. *To place* a sharp-pointed knife or a bottle of poison in the hands of a babe would certainly be as sane an act as to place in the hands of children or others inexperienced in the dangers and handling of them, such destructive implements as blank cartridge pistols, cannon, powder and giant crackers have proved themselves to be.

We urge it on the members of the medical profession, and on the press of our country, to continue with us in this crusade for a safe and sane celebration of our nation's birthday. The work of the past few years has had its results. May the movement have accelerated speed!

Clinical Reports

SUBCUTANEOUS EMPHYSEMA IN A CASE OF BRONCHOPNEUMONIA.

FRED S. SPEARMAN, M.D., C.M.

WHITING, IOWA.

Instances in which this condition is as widespread over the body as in the following case are not of frequent occurrence; another interesting point in this case was the rapid initial development of the emphysema. Nothnagel regards subcutaneous emphysema as a very grave complication in bronchopneumonia.

Patient.—J. B., aged 16 months, with the exception of a slight cold last winter, had always been healthy.

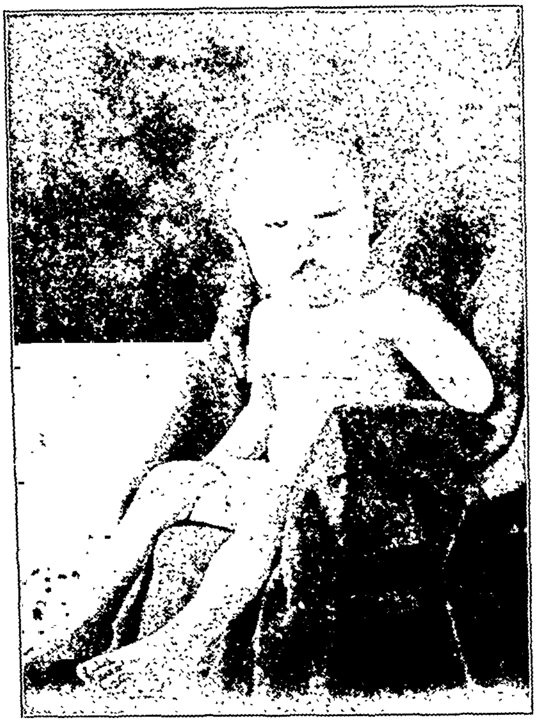
Family History—Both parents are living and in good health. An older brother and sister were recovering from the whooping cough. Father's mother died of phthisis.

Present Illness.—I first saw the patient on June 4. The parents informed me that she had been suffering from whooping cough for about five weeks, but a day or two before I was called she developed a high fever with vomiting, and the cough altered in character.

Examination.—This showed fine crepitant râles, general throughout both lungs, respirations about 70 to the minute, pulse 160, temperature 102.6 in the axilla. Cough was hard and tight, expiration grunting, and nervous symptoms marked, such as clutching at the bed clothes and restlessness. The face was of a dusky hue; in short, all the symptoms of a severe bronchopneumonia were present.

Course of the Disease.—For the next three days there was little change in the general condition. The râles, however, became more liquid as secretion developed. There was considerable meteorism, and the rectum would become partially prolapsed when the child coughed.

On the afternoon of June 8 a slight swelling appeared on the left side of the neck, low down. That same evening, during a severe coughing spell, the swelling suddenly increased in size and spread in a few moments' time up the side of the face and on to the left temple and upper eye lid, completely closing the eye. By the following morning the upper part of the chest before and behind was involved, and the day after the entire scalp and right side of the face so that the right eye was also closed. During the ensuing three days the tumefaction extended over the remaining portion of the chest, as far down posteriorly as the sacrum, and down both arms.



Over the portions where the swelling was most marked the skin was tense and shiny, the swelling was elastic and nonresistant to pressure, crackled under the finger and was tender. The crackling resembled the sound made by squeezing a rag saturated with soap suds. I diagnosed the condition as subcutaneous emphysema resulting from a ruptured bronchus.

Whether it was a mere coincidence or not, with the appearance of the emphysema the general condition greatly improved, the nervous symptoms disappeared so that the child rested easily, grunting expiration soon nearly ceased, expectoration became profuse and easy, and the face showed a much better color. Pulse and temperature were also lowered, the latter dropping by lysis until, by June 17, it had reached normal. It occurred to me that possibly the escape of the air into the tissues had a favorable effect by relieving intrapulmonary pressure. By June 27 the emphysema had entirely disappeared, being last noticed on top of the head, and when I last saw the little girl, July 4, she had apparently recovered her usual health.

Treatment.—This was along the lines commonly employed in bronchopneumonia. The emunctories were kept active by means of frequent sponging with tepid water, calomel and enemata for the bowels, and plenty of water to drink. Diet consisted of milk and light broths. The chest was kept protected by a cotton batting jacket. A saline mixture containing iodid and citrate of potash with aromatic spirits of ammonia was administered to promote bronchial secretion and keep it free. The child vomited very easily, the attacks of coughing frequently producing emesis, so that it was rarely necessary to employ emetic measures in order to get rid of mucus.

The photograph was taken after the emphysema had commenced to subside, but shows clearly the puffy appearance of the eyelids, and also in part the swelling over the upper chest in front and behind.

CARBOLIC ACID BURN.

EFFECTUAL, ALTHOUGH LATE, USE OF ALCOHOL.

T. J. SWISHER, M.D.

RAWLINS, WYO.

A young lady employed in a drug store started home from work in the evening, taking with her a number of small parcels to deliver to patrons of the store who lived in her neighborhood. Among these parcels was an ounce bottle filled with 95 per cent. carbolic acid. In some way the bottle was broken, pouring the contents over both hands. As it was dark, she did not at first know what the bottle had contained, and only after the hands began to burn did she take the trouble to wipe off the excess of acid with her handkerchief. After reaching home, she applied a dressing of vaselin and it was not until over an hour after the burn occurred that I saw her. At this time the white eschar covered the entire palmar surfaces of both hands as well as the palmar and interdigital surfaces of all the fingers. Sensation over this surface was entirely absent and the fingers could not be voluntarily flexed. The hands were at once cleansed of the vaselin and put into an alcohol bath, with constant rubbing. Aften ten minutes the color began to return, a tingling sensation developed and the fingers could be voluntarily flexed. The alcohol bath was continued for twenty minutes and all evidence of the burn had then disappeared except a slight tingling and stiffness of the fingers which persisted for several hours, but which almost entirely disappeared by the following day. Aside from a little cracking of the skin over the finger tips and an unpleasant dryness which persisted for a week, the recovery was complete and immediate.

To me the interesting feature of the case was the length of the interval between the receipt of the burn and the application of the alcohol.

Believing this to be a topic worthy of discussion, I would like to hear from others with special reference to the length of time that may elapse before alcohol loses its power as a local antidote for this acid.

Diazo Reaction in Tropical Diseases.—A. Austregesilo of Rio Janeiro has been studying this subject since 1900. He found the diazo reaction almost constantly present in bubonic plague. Certain drugs modify the reaction, and as the disease progresses to a fatal termination the reaction generally fails. Antiplague serum does not affect it. In yellow fever and in malaria the tests were invariably negative. In beri-beri the reaction was always negative, as well as in leprosy, in scurvy and ankylostomiasis. In typhoid fever and in tuberculosis his findings were the same as those reported by others elsewhere. In smallpox the reaction was always present. His report is published in the *Revista Med.-Cir. do Brazil*, xiii, No. 3.

FOURTH OF JULY CASUALTIES.

In this issue appears an annual summary of the accidents due to the idiotic methods of celebrating our national anniversary. The list, which no one can claim to be absolutely complete, is yet sufficiently appalling. There must be hundreds of minor injuries and many of a more severe character occurring on Fourth of July that never receive any public notice, and even deaths directly or indirectly due to such accidents undoubtedly escape publication or are miscredited to other causes. If we could have the full total of what we owe of human life and human suffering to this cause fully revealed, the facts would be still more formidable.

Nevertheless, the figures this year are full of encouragement. While the total of non-fatal injuries is greater than those of two years preceding, the total of deaths is still on the decrease, especially as compared with the figures of 1903. The difference is still more striking when we consider only those caused by tetanus, the most terrible death-causing factor. The toy pistol which has been so important a factor in the tetanus mortality in past years seems to be in the process of legal suppression, and what has been done in this particular case is possible with other of the important causes, a fact which is a very encouraging indication for the future. We can credit also to the direct use of antitoxin as a prophylactic, especially in some of our larger cities like St. Louis, a certain proportion of the prevention of Fourth of July tetanus. The use of this antitoxin is likely to increase and we may be hopeful of still better results in the future. The giant cracker is also a less fruitful cause of lockjaw, a fact probably due in part to the laws against its use. While the total deaths from tetanus, as well as from all causes, is not so markedly less than that of 1904, though very strikingly so as compared with 1903, we do not believe that this indicates that we have reached the normal limit of the result of effort for its decrease. The only satisfactory outcome will be reached when Fourth of July accidents are abolished as a cause of death or serious injury.

When we take the total of all injuries into account, the figures are, at first sight, less encouraging, as they exceed those of both of the previous years. This may be due, in part, to better reporting of minor injuries, owing to the interest that has been aroused of late years in the subject, and we think this is likely to be the fact. If so, it is an encouraging symptom rather than otherwise. One thing is certain, it is our duty as a profession to keep up the agitation. The public is not yet half educated as to the importance of the matter. If it were, our municipal and other authorities would be less tardy in their promulgation of proper regulations and less lax in their enforcement—two causes which are responsible for a large part, if not nearly all, of the evil as it exists. If we do our full duty, the time will come, and we believe is not so far distant, when the records of our national holiday will not be like those of a little war.

THE FUSO-SPIRILLAR SYMBIOSIS.

Recent medical literature contains numerous reports of the presence of fusiform bacilli commonly associated with long spirilla on various inflammatory and necrotic processes. In 1893, Rauchfus observed this symbiosis in ulceromembranous angina. In 1896, Vincent, who has made many reports of these organisms, described their presence in hospital gangrene and also in a form of ulcerative angina, since then often spoken of as Vincent's angina. Bernheim noted the presence of the same bacteria in stomatitis. Since then numerous corroborative observations have appeared from various parts of the world, thus indicating that these organisms are distributed widely. Indeed, the fusiform bacillus appears to be a normal inhabitant of the buccal cavity, and it is assumed by Vincent and others that it assumes a pathogenic rôle under special conditions only, more particularly lowered general vitality from all causes and other microbic lesions. Spirilla have been found in healthy mouths also and on normal tonsils, and they are regarded by many as the same organism as Miller's *Spirochæta denticola*. The first list of the different lesions in which these organisms have been demonstrated is constantly growing. Sometimes the fusiform bacillus only is present, but equally as often, if not oftener, both the microbes are present; hence, the term fuso-spirillar symbiosis, which is used by Vincent in a recent article on the subject.[1]

In addition to angina and stomatitis, frequently of an ulcero-membranous character, and noma, the organisms under consideration have been found in fetid oral abscesses, in hospital gangrene, in appendicitis (Vincent observed them in 11 of 19 cases), in gangrenous ulcers of the penis, bronchiectasis, periostitis and fetid abscess of the leg, and in cerebral abscess. It is important to bear in mind that other organisms, especially pyogenic cocci, are always present also. Although the interrelations of these various bacterial forms have not been worked out as yet, many of the lesions mentioned, particularly those associated with necrosis, have such manifest peculiarities that it does not seem likely that the fuso-spirillar symbiosis is wholly devoid of pathogenic significance. Thus, in the microscopic sections of the tissues involved, filamentous organisms are found at the line of advancing necrosis in large numbers. Experimentally the infection of materials from ulceromembranous angina, etc., is followed by localized gangrene and abscesses, but here it is manifestly impossible to determine the exact part played by the various bacteria present. This question can be settled only by continued work with pure cultures. Ellermann, as well as Weaver and Tunnicliff,[2] have obtained small abscesses with pure cultures of the bacillus. So far, it has not been possible to isolate the spirillum in pure cultures, although Weaver and Tunnicliff obtained evidences of the proliferation in mixed cultures with the fusiform bacillus and other bacteria. The fusiform bacillus, however, can be isolated in pure culture. Veillon and Zuber, in 1898, were the first to grow a fusiform bacillus which they found in a case of appendicitis. In 1904, Ellermann grew it from ulceromenbranous angina and gangrenous stomatitis, and more recently Weaver and Tunnicliff obtained pure cultures from angina, stomatitis and diphtheria. The bacillus in all cases was an obligate anaërobe that grew at the body temperature only. Further study may show that what is here spoken of as a "fusiform bacillus" in reality represents several varieties, although the descriptions of Ellermann and of Weaver and Tunnicliff appear to tally quite closely.

---

[1] Ann. de Dermat., 1905, vi, 5. Abstracted in The Journal, July 29, 1905, p. 359.

It is important that the lesions, especially of the mouth and throat, in which the fuso-spirillar symbiosis occurs, should be recognized and studied carefully by clinicians in order that, if possible, a more perfect differentiation may be secured and clinical relations of the processes better understood. In order to recognize the lesions definitely, it is necessary to study carefully cover-slip preparations and to make anaërobic cultures. The usual method followed in the bacteriologic examination of the throat in suspected diphtheria does not suffice, and cases of membranous angina in which the diphtheria bacillus is absent merit particular attention. Deposits about the necks of the teeth, often associated with bleeding gums, in children, especially in institutions, also require special attention. On the whole, it is clear that the time is now at hand when progress in the knowledge of many lesions of the mouth and throat and of fetid and gangrenous processes elsewhere requires the use of anaërobic cultural methods, as well as the aërobic hitherto so largely employed alone.

THE ULTRAMICROSCOPIC, FILTERABLE VIRUS OF HOG CHOLERA.

Hog cholera is a very destructive disease and consequently of great economic importance. It is proving to be an important disease from the purely scientific point, as well because of recent significant discoveries in regard to its etiology. It is on this latter account that a gist of certain recent investigations, particularly by the Bureau of Animal Industry at Washington,[1] under the direction of D. E. Salmon, is presented.

When the hog cholera bacillus (*B. choleræ suis*) was discovered, twenty years ago, it was believed that the etiology of this disease was solved. Facts were continually encountered, however, that did not harmonize with the generally accepted view that the disease is caused by the bacillus. A form of acute hog cholera in southwestern Iowa, in particular, presented high contagiousness, the blood of infected animals being virulent on subcutaneous injection into healthy, non-immune animals, and on recovery a definite immunity—facts that are not observed in experimental infections with the hog cholera bacillus which, it must be borne in mind, is pathogenic to hogs and other animals on experimental inoculation, as well as very frequently present in animals sick with spontaneous hog cholera. De Schweinitz and Dorset found that the actual cause of this form of hog cholera passed through the finest porcelain filters, and that it consequently belongs in the class of so-called filterable or ultramicroscopic viruses, the number of which appears to be increasing slowly. These observations have been confirmed and enlarged by Boxmeyer[2] of Detroit and by Dorset, Bolton, and McBryde.[1] The latter investigators ascribe the new departure of the study of hog cholera to the skepticism felt by the late De Schwenitz as to its generally accepted bacillary origin.

The mysterious virus thus demonstrated is known as yet only by the effects it causes on injection into susceptible hogs, because all efforts have failed to reveal by staining or culture any visible microbe in the virulent filtrates. This virus is not a toxin, because the disease caused by filtered blood serum is transmissible through succeeding animals, a fact that shows that the causative agent possesses the power to multiply. In this respect the filterable virus of hog cholera resembles the virus of foot-and-mouth disease, as well as other diseases of this peculiar group, the only representative of which that occurs in the human being, so far as is now known, being yellow fever.

While the filterable virus must be regarded as the prime cause of the disease studied, the part played by the hog cholera bacillus can not be neglected. In the first place the Washington investigators are not willing to deny that the bacillus, under certain circumstances, may cause an independent disease; on the other hand, however, it seems quite certain that the filterable virus so reduces the natural resistance of the hog that the hog cholera bacillus is able to invade the infected animals and thus probably materially influence the result. Whether the bacillus is a normal inhabitant of hogs is not established definitely, but certain facts point in that direction. The actual demonstration that such is the case would materially encourage the view that the bacillus is a secondary invader. On account of the great probability that the relations between the ultramicroscopic virus of hog cholera and the bacillus of hog cholera are those of primary and secondary infecting agents, there is furnished an interesting analogy of what undoubtedly is the case in certain human diseases, especially severe forms of scarlet fever and smallpox, namely, that the primary cause, the actual contagious element, in the case of smallpox especially being capable of wide aerial dissemination, so lowers the general resistance that the otherwise harmless streptococci in the throat are able to invade the tissues and lead to the general streptococcus infection so commonly the case in fatal forms of these diseases. It may be permitted, too, to indulge in the speculation that similar complex conditions as in hog cholera may exist in other human diseases, such as whooping cough, for example, as well perhaps as in others, the etiology of which is now regarded as established.

---

[2] Journal of Infectious Diseases, 1904, ii, 446. The literature is given fully in this article.

[2] Jour. of Infect. Dis., 1905, ii, p. 359.

The demonstration that filterable virus is the essential cause of outbreaks of so-called hog cholera naturally leads at once to new attempts at more effective therapy than heretofore available. Experiments with promising results have been made already by Boxmeyer and McClintock,[3] and the outlook seems favorable for ultimate success.

REMOVAL OF OVARIES FOR CARCINOMA OF THE BREAST.

The relations which exist between the breasts and the internal sexual organs, the uterus and ovaries, while apparent to every observant practitioner, so far as their *modus operandi* is concerned, are as obscure as ever. Aside from the gross changes in the breasts incident to childbearing, more subtle ones are present in many women at each menstrual period. The idea that such a physiologic condition might have a bearing on pathologic processes, and particularly on new growths in the breast, was first, we believe, suggested by the English surgeon, Beatson. Reasoning from analogy that if an ovarian injury in a cow would cause suppression of the milk, ovariotomy in a woman might also affect the mammary glands, he suggested castration in inoperable cases of mammary carcinoma. While the logic of Beatson's reasoning may not appeal to every one, his belief led him to carry into effect the natural deduction to be drawn from it, viz., removal of the ovaries in cases of hopeless mammary carcinoma. Some of the results obtained by Beatson and other surgeons in Great Britain have certainly been striking. While absolute cures have rarely been effected, the operation seems to have produced striking amelioration in a considerable number of cases.

Michels has called attention to the fact[1] that this work has been almost overlooked outside of the British Isles. He cites some remarkable cases to show the marked palliative effect which the operation may have. In at least two cases, quite large areas of carcinomatous infiltration of the breast or chest wall disappeared and had not returned in one case five and in the other eight years after the ovariotomy. Results like these were, however, exceptional, in most instances there was both local and general improvement, but in the long run the growth returned. The local improvement usually took the form of a decrease in pain, and accompanying this in a fair percentage of the cases a reduction in size of the tumor took place. In some instances, ulcerated areas took on a healthy appearance and completely healed up.

There is some dispute as to the indications for this operation. Many British surgeons advise operating even after the menopause, or at least for a year or two after it. Michels is opposed to this, and thinks that this operation should be restricted to women between 40 and 47 years of age. In young women, he thinks the operation is advisable on account of the well-known virulence of carcinoma in them; after the menopause the operation is uncalled for, as Nature has practically done the same thing in a different way. If possible, it is advisable to remove the recurrence of the carcinoma at the same time that the ovariotomy is done.

It is fair to speculate on the way in which the removal of the ovaries influences mammary new growths, and several interesting points arise. If the effect is due to the suppression of an internal ovarian secretion which was stimulating the mammary neoplasm, we must assume that the tumor cells had inherited in a marked degree the possibility of being stimulated, notwithstanding the fact that they are far from being normal breast cells. One would naturally, we think, tend to compare the process described with the shrinkage of myomata, which often follows the menopause. It is well to bear in mind that, at the change of life, the breasts, as well as the other sexual organs, undergo atrophic changes. May it not be that the oöphorectomy simply brings on an artificial menopause and leads in this way to atrophy of the tumor? Here, again, we would have to assume that the tumor cells had inherited the characteristics of their parents, the normal breast cells. There is really nothing very far fetched in this assumption, however, for we know of tumor cells which are able to secrete substances like normal cells. Certain adenomata of the liver, for example, secrete bile. Like everything connected with the question of internal secretions, the subject is a fascinating one, but, like many subjects of a pathologic nature, it brings into the glare of the limelight our weaknesses in physiology. There are still many things to be learned regarding the connection between the breasts and the internal sexual organs.

THE RELATIONSHIP BETWEEN GENERAL PARALYSIS AND TABES DORSALIS.

The similarity which exists between general paralysis of the insane and tabes dorsalis has been noted and commented on since shortly after Westphal accurately described the latter disease. The concurrence of the two diseases is relatively so common, the relation of both conditions to syphilis is so frequent, and the pathology of the two diseases so similar that one is tempted to assume that they represent different phases of the same fundamental condition. It is the French school of physicians who have most ardently supported the view that unity between the two diseases exists, though some German observers, notably Schaffer, strongly support them. There are certainly many points in favor of such a view. According to Nageotte, two-thirds of the cases of general paralysis are accompanied by tabes; an individual may start with the latter disease, then mental symptoms may set in and the picture change to that of general paralysis; the brains of tabetics may show the anatomic changes of general paralysis; tabes may be masked by general paralysis. All these facts emphasize the intimate relationship which exists between the two diseases, and while many hold that the two conditions are separate, those who have had an opportunity to study both neurologic and psychiatric cases seem inclined to favor such a unity.

---

[3] Jour. of Infect. Dis., 1905, p. 368.

[1] Münch. med. Wochft., vol. lii, No. 24, Ab. in Journal, p. 663.

The question has been restudied recently by Cotton, who has had the advantage of being able to select from a large number of patients some twelve of which could be carefully followed from the beginning to the end of their sickness. The cases which were studied were those which would be classed by some authors as taboparalysis. This term includes any case which presents symptoms of a combination of the two diseases, and, of course, includes three possible groups of cases, i. e., those in which the tabes preceded the paralysis, those in which the opposite condition occurred, and those in which the two diseases progressed side by side. All varieties of cases were studied by Cotton and most careful records were kept of the disturbances in sensation, the pupillary reaction, the various crises, bladder and rectal symptoms, and the condition of the deep reflexes. The result of the investigations lead Cotton to believe that the two diseases present many analogies in their etiology, symptomatology, and course, and that they occur so frequently together that it must be more than a mere coincidence. The clinical symptoms of the two diseases when combined is the same as when they exist apart, though there are differences in degree which depend on the predominant anatomic localization of the pathologic process. The absolute identity of the two diseases can not, of course, be settled until more is known of their pathogenesis.

This study of Cotton[1] does more than to draw attention to the similarity between two very common diseases. Reading between the lines, one gathers the impression that much of the disagreement which has existed and which still exists on this and kindred subjects is due, partly at least, to the separation of neurology from psychiatry. This, no doubt, produces experts in both of these subjects, but it narrows their field of vision. The subjects are so closely allied, and run so insensibly the one into the other that they should never have been divorced, and only were divorced by necessity. The stigma attaching to the insane has now been largely removed, and we hope that in the near future there will be in America, as there are now in Europe, more psychiatric clinics in which acute cases of insanity, especially, are seen and studied by the same man who sees and studies neurologic cases.

THE COUNTY SOCIETY AND THE ORGANIZATION MOVEMENT.

Since the reorganization plan was adopted in 1901—only four years ago—remarkable progress has been made in unifying the medical profession in the United States. The influence of the new spirit permeating the profession is being felt not only in the reorganized states, but even in the two or three states which have not adopted the new plan. Any one who will compare the conditions of to-day, in any part of the country, with conditions of five years ago will realize that a remarkable change for the better has taken place. "Unity, peace and concord," as Osler put it, as well as a spirit of scientific progress, are distinguishing features of the new era.

The recognition of the importance of the county society as a unit is the basic principle on which the work of organization has been and is being conducted. The most important unit in the scheme of organization is the county society; then come the state association, and the American Medical Association. The last is the least important of the three; the first—the county society—the most important. Every effort that has been made by the American Medical Association in developing organization has been made with the above principle in view—the importance of the county or local society.

Now the machinery all over the country is practically complete, and results must be looked for. These are many, but the most important is that of making the county society something more than a name—something more than a piece of machinery lying idle, rusting: it must be made a living force to dignify medicine as a profession, to increase public respect for, and to elevate the material, moral and intellectual status of, that profession. How can this be accomplished; how can the county society be made a power for good to those who belong to it, and to the community? In many and various ways. The first thing to be recognized, however, is that the average county society, if left to itself, will become dormant. There are many exceptions, but this is the rule. Another thing must also be appreciated: if a society can be made a living, active force for good in one community, a similar society can be kept up in another community where similar conditions exist.

It was the recognition of these facts which prompted the House of Delegates and the Board of Trustees to ask Dr. McCormack to continue his work for another year. As Chairman of the Committee on Organization, he has been devoting a large part of his time in the recent past to organization work, although no small part of his efforts was exerted in aiding the adoption of the uniform plan by the various constituent associations. Hereafter practically all of his efforts will be in the line of building up county societies. His experience has taught him what can be accomplished and how. He has seen the society in one county doing magnificent work, while in the same state, with exactly the same conditions, the society in another county was practically dead; and he has seen why, has shown the members of the dormant society why, with the result that it too has become a living force.

---

[1] Am. Jour. of Insanity, LXI, No. 4.

In other words, as he has gone from county to county and from state to state, he has acquired an experience with the methods and conditions that can, with great benefit, be imparted to physicians of other communities. Methods of regulating and upholding fees, and of securing the indispensable post-graduate work in scientific medicine, are thus compared and classified and made available for use everywhere. He has learned from observation and from experience what has been done in some communities in stimulating the organization of the profession; what methods have been adopted for dealing with quackery and with the nostrum evil; what has been done to bring about better relations between the physician and the pharmacist, and, in fine, what has proved to be the most effective methods of dealing with all the business and scientific sides of medicine. Thus Dr. McCormack is working, not as the agent of The Journal, not to build up the American Medical Association, but to benefit the medical profession of the United States, individually and collectively.

But if the whole country is to be covered, individual counties can not be visited, and should not be except for special reasons. The societies of a councilor district should unite in a district meeting so that mutual benefit may accrue to many and not to one society alone. The councilor should take the initiative, but the officers of a county society who desire Dr. McCormack to come into their community should write to their councilor to invite him. It must be remembered that he will not go into any state or into any district of a state unless the profession of that state or district desires that he should do so. All expenses connected with this work are met by the American Medical Association.

A MISERABLE OUTRAGE.

The depths of venality to which the nostrum makers descend in order to gather in a few more dollars are beyond the belief of those possessing normal human sympathy. One of the worst recent instances of this sort of inhumanity is now to be found in some newspapers of the Southern states. Inserted as news, not as an advertisement (*vide*, for example, the Shreveport, La., *Times* of August 16, 1905) appears what is called "an interview with Dr. Hartman concerning the yellow plague." Dr. Hartman needs no introduction, being widely known to physicians as that citizen of Columbus, Ohio, who has amassed a colossal fortune by selling to a gullible public as a "medicine," under the name of peruna, low-grade whisky flavored with cheap bitters. Aided by two or three avaricious renegade physicians, he has enmeshed in his fraud thousands of clergymen, lawyers, politicians, etc., and, if what is reported is true, has undoubtedly created an appetite for intoxicants in unsuspecting men and women and in innocent children. In the present instance, the fraud on humanity is at least equal in perfidy to that of the traitor who sells out his country. A summary of this interview is being spread broadcast over a portion of the United States for the benefit of yellow fever sufferers. "In all such cases it is advisable for the person to take peruna." "Begin taking peruna at once in teaspoonful doses so as to harden and heal the mucous membrane against the possible invasion of the yellow fever poison." (!) "Peruna should be used during the whole course of the epidemic." "I feel sure that any person following this advice is in no danger of taking yellow fever." What could be worse? Shall such things be permitted to continue? Can nothing be done to protect a fear-stricken people from such damnable outrages on humanity? And what about newspapers that will join in a conspiracy of this kind to defraud their readers for a few paltry dollars?

YELLOW FEVER.

In New Orleans the epidemic is held in check, the rate of increase not rising, while for the week there is a slight falling off in the number of new cases. Unfortunately, the pest spreads outside the city, and in some places the situation is grave. As the disease spreads it is demonstrating the failure of the shotgun quarantines. With dramatic unconcern the disease has penetrated some of the quarantines that have been reported to be "airtight." In our last week's issue we were glad to publish a letter from a correspondent at Natchez, Miss., who maintained that our strictures against the barbarity and futility of the shotgun quarantine were unwarranted. Writing under date of August 15, our correspondent said: "We know that non-intercourse with infected areas will prevent the introduction of the disease into healthy towns, and propose to follow up the plan that has proved safe in other times. . . . But this city is certainly closed to the world for the present." Yet, twelve days later, Natchez admitted to the world that it had nine cases of genuine yellow fever, and three additional suspicious cases. Nothing could more clearly illustrate the great weakness of the non-intercourse quarantine, leaving out of account its brutality of administration in so many places. It lulls the people into a false sense of security, so that the really necessary prophylactic measures either are not taken at all or are executed in a half-hearted way that renders them worse than useless. With all its rigors and entailed human suffering, the shotgun quarantine always fails of its object to arrest every incomer. There is ever a loophole—a careless or avaricious or potatious guard, or a byway that escapes watch. The traveler of the better class, going openly, can not miss detention or deportation, but the criminal and the tramp, and at times the local celebrity of powerful connections, can always find an open door. Town after town in the infected area is demonstrating these truths. It is to be hoped that these widely-known and manifold failures of the rigid quarantine as the sole means of defense against an epidemic will bring about the next most useful lesson to be taught by the present calamity. The money and energy spent on irrational quarantines, with the necessary contribution of still larger sums, if devoted to general and permanent sanitation, the destruction of mosquitoes, the oiling and draining of swamps, marshes and ponds, the close screening of houses, cisterns and beds, and the proper, humane, screened isolation of every suspicious case of illness, would accomplish the good that is desired; and there are no other known means of arriving at this end. It is impossible to believe that the present lessons will be forgotten in the future.

SLEEP-DRUNKENNESS.

Consciousness or the waking state is the condition in which active communication with the external world exists through the intermediation of the senses. It may undergo various modifications, some of a normal character, as in sleep, others of a morbid character, such as coma. During sleep, there is reason to believe, certain subconscious processes, partly of perception, partly of ideation, continue, and of which there is at times recollection and at other times none. This statement is exemplified in connection with dreams. In the derangements of consciousness symptomatic of morbid states, such as that which occurs, for example, in the course of epilepsy or of uremia, there is, as a rule, no memory of events that have transpired during this time. The dividing line between the normal and the abnormal, however, is at times so tenuous and the question of recollection or not is involved in so much uncertainty that this factor can not be considered as a means of differentiation. Under the term sleep-drunkenness or somnolentia has been described a condition in which during apparent sleep individuals perform purposive acts, at times, of a most complex and hazardous character and of which, subsequently, they have a clear and distinct recollection. A striking instance of this disorder has recently been placed on record by Dr. E. W. Taylor.[1] An otherwise healthy man, aged 31, who for years had occasionally walked in his sleep, related that he was compelled by an irresistible impulse to leave his bed, remove a screen from a window and slide down a copper water spout to the ground, scraping his hands and feet in the act. On reaching the bottom he realized what had taken place and quietly returned to bed. He maintained that he had not lost consciousness and that he had a distinct recollection of everything that had transpired. On another occasion, in his nightshirt, he entered, through a window, the bedroom of another man. At still another time, he vaulted from a third-story window, being awakened while hanging from the sill. He had had many other experiences of a similar character. Awaking was unattended with vertigo or confusion. According to the patient's explanation, his actions were impelled by an overmastering fear from a frightful dream. He had never seriously injured anyone, but he stated that if he were forcibly prevented from making his escape from the threatened danger he would stop short of no degree of violence to attain the desired end. The condition in question has thus clearly important medicolegal bearings, as the matter of responsibility might readily be brought into question. The term somnolentia, as applied to the disorder, appears wholly inadequate, while sleep-drunkenness seems lacking in accuracy as a descriptive term. Dana considered the condition a kind of active nightmare, but it seems to be an active form of somnambulism.

VACCINATION DURING ERUPTIVE STAGE OF SMALLPOX.

In a recent issue of the *Lancet*,[1] Dr. J. Cooke Hibbert claims that vaccination or re-vaccination may be successfully performed during the eruptive stage of smallpox, and cites eleven cases in support of his contention, the vaccination in these cases having been performed on the first, third and thirteenth day. This is by no means an uncommon occurrence, as has been demonstrated frequently at the Chicago Isolation Hospital. Patients vaccinated on the second and third day of the eruption, or up to the eighth day, will, as a rule, have a typical take, but not after this time. In a paper by Dr. Heman Spalding,[2] published in The Journal several years ago, reference is made to an experimental vaccination of over one hundred smallpox patients after the eighth day of the eruption. In none of these cases was there a take. The case reported by Hibbert in which vaccination was successful on the thirteenth day is probably one of a spurious type, although it might have been a perfect vaccination. These findings only prove that the tissues are not impregnated with the immunizing substances of smallpox. The fact that vaccination or re-vaccination was successful in a case having a rash of doubtful character is not an argument against that case being one of smallpox, but in such a case a positive diagnosis will have been made before there is any evidence of the outcome of the attempt at vaccination. Hence, vaccination for diagnostic purposes during the eruptive stage of any exanthem is of no value whatever.

Medical News

CONNECTICUT.

Cedar Mountain Hospital.—The free bed fund for Cedar Mountain Hospital for Deserving Consumptives now amounts to more than $5,300.

Norman Kerr Lecture.—Dr. T. D. Crothers, Hartford, has accepted an invitation to deliver the first oration in the Norman Kerr memorial lectureship at London, Eng., October 10.

Personal.—Dr. Wyeth E. Ray, Hartford, has been appointed associate medical director of the Travelers' Insurance Company.——Dr. Elias B. Heady, Milford, was seriously injured August 12 in jumping from an unmanageable automobile.

Nominal Damages.—In the damage suit of Lorin A. Barnes, Torrington, against Dr. William H. Carmalt, New Haven, in which $25,000 damages was claimed for the alleged sewing up of a piece of gauze in the abdomen, in an operation, the Superior Court awarded the plaintiff nominal damages.

---

[1] Boston Med. and Surg. Jour., April 6, 1905, p. 398.

[1] Lancet, London, May 20, 1905.

[2] The Journal A. M. A., Oct. 11, 1902, p. 906.

July Deaths.—During July 1,648 deaths were reported in the state, equivalent to an annual mortality of 20 per 1,000. Of this mortality 37.3 per cent. occurred in children under 5 years. The chief death causes were: Diarrhea, 466; nervous diseases, 159; accidents and violence, 135; consumption, 110; heart disease, 109, and pneumonia, 44. Infectious diseases caused 189 deaths, or 11.3 per cent. of the total mortality.

ILLINOIS.

Typhoid Epidemic.—Typhoid fever is said to be prevalent in and around Greenville.

Unlicensed Practitioner Departs.—David Johnson, Waukegan, who claimed to have "an interstate and international license," and was fined $100 and costs in March for practicing without a license, learning that a warrant had been issued for his arrest, fled from the city.

Chicago Deaths.—During the week ended August 26, 561 deaths were reported, equivalent to an annual mortality of 14.68 per 1,000. Of these 179 were under one year old and 230 under 5 years of age. Acute intestinal diseases caused 152 deaths; consumption, 49; violence, 34; pneumonia and heart disease, each 33; nervous diseases, 27; nephritis, 26, and cancer, 24. Typhoid fever caused 12 deaths.

Personal.—At the annual meeting of the medical staff of the City Hospital, Moline, Dr. Albert M. Beal was elected president; Dr. Albert R. Beal, vice-president, and Dr. August H. Arp, secretary.——Dr. Annie B. McCallum Alguire, Belvidere, was thrown from a buggy August 20, breaking a rib and sustaining other serious injuries.——Dr. Richard E. Shurtz, Champaign, who has been seriously ill with septicemia in Denver, is recovering.——Dr. Joseph T. White, Freeport, was operated on for appendicitis at the Wesley Hospital, Chicago, August 16, and returned home three days later.——Dr. James E. Stubbs, Chicago, who has been seriously ill with septicemia at Colorado Springs, has returned to Chicago and is improving.

MARYLAND.

Personal.—Dr. J. T. Payne has removed from Corbet to Sunnybrook, Baltimore County.——Dr. Howard Bratton of Elkton was recently thrown from his buggy and dragged some distance, being badly injured.

Open-Air Sanitarium in Blue Ridge Mountains.—Through the efforts of the Quarter Club, Baltimore, an open-air sanitarium for consumptives has been set in operation at Mount Airy, among the foothills of the Blue Ridge Mountains. It was opened July 28 and has now seven patients. It is on a high hill near the Baltimore & Ohio Railroad, and consists of a seven-room cottage, with ample porches, and six open-air shacks on the edge of a forest. The current expenses are borne by the Hospital for Consumptives of Maryland. It is to be open winter and summer, and only the most hopeful cases are to be admitted. Thus has begun unostentatiously a work which doubtless will become one of the most useful and important charities in Maryland.

Baltimore.

Removals.—Dr. H. Walker Hutchins has gone to North Liberty, Ind., to practice.——The State Board of Health has removed its offices to its old quarters in the burnt district.

Visitor from Australia.—Dr. M. U. O'Sullivan, F.R.C.S.I., senior surgeon in St. Vincent's and the Woman's hospitals, Melbourne, Australia, visited the Baltimore hospitals last week.

Typhoid Not Unusually Prevalent.—The mayor makes the statement that typhoid fever is not more prevalent here than usual at this season of the year, and that the 140 cases said to exist represent all the cases in institutions since July 1. Many of these are now well and on the street.

College Denies Indebtedness.—The answer of the Woman's Medical College to the bill filed on July 25 for the appointment of a receiver, denies that the institution is insolvent, says that the allegations of the petitioners are "recklessly and wantonly made and untrue," and avers that it has never been customary for the college to pay its lecturers for their services, and denies that it is indebted to them for such.

MINNESOTA.

Founds Hospital.—The executor of the estate of the late Mrs. Mary Elliott has conveyed from the estate property valued at $175,000 in trust for the founding of a University of Minnesota Hospital at Minneapolis, as a memorial to the late Dr. Adolphus F. Elliott.

Personal.—Dr. Jehiel W. Chamberlin, St. Paul, who sailed from Montreal for Europe July 6, sailed for home September 1.——Dr. George E. Benson, Minneapolis, has returned from Europe.——Dr. E. H. Beckman, medical inspector and assistant bacteriologist of the State Board of Health, has been elected city physician of Minneapolis.——Dr. David H. Lando, St. Paul, has been given honorable mention for a thesis submitted at Vienna.——Dr. Frederic J. Plondke, St. Paul, is studying in Europe.

Murray County Medical Club.—Physicians of Murray County met at Slayton August 1, and organized a club to promote good-fellowship among the profession of Murray County and adjacent counties. The following officers were elected: President, Dr. Emil King, Fulda; vice-president, Dr. Walter E. Richardson, Slayton; secretary and treasurer, Dr. Leon A. Williams, Slayton; and censors and committee on medical ethics, Drs. Milton A. Trow, Avoca; George G. Balcom, Lake Wilson, and C. C. Walker, Currie.

NEW JERSEY.

Health Officers Elected.—Dr. Samuel D. Mayhew was elected health physician of Bridgeton August 24.——Dr. Duncan W. Blake was elected medical inspector of Gloucester City August 21.

Physicians Refuse Lodge Work.—All the physicians of Trenton have banded together in an effort to overcome lodge practice, and have signed an agreement not to accept contract lodge work in any form.

Milk Dealers Arrested.—Warrants have been served on two dealers at Egg Harbor to appear for adulterating food, as a result of the inspection by the State Board of Health a few weeks ago. Both men denied the charge, but will appear for trial before the Circuit Court.

Suicides Increase.—The annual report of the State Board of Health shows a material increase in the number of suicides during 1904. During the year there were 314, as compared with 265 for the previous year. The 1903 showing is at the rate of 15.70 per 100,000. Of the suicides 9 were residents of Trenton, 4 of whom took poison, 2 used firearms, 1 a knife and 1 threw himself from a height. Poison caused 153 suicides and 112 died by asphyxiation. The age most frequently selected was between 35 and 45 years. Of the number recorded 112 were born in America, 64 in Germany and 24 in Ireland.

NEW YORK.

Less Typhoid.—There is less typhoid fever in Buffalo than there was at the same time last year, but many cases of pertussis still exist.

Buffalo Personals.—Dr. Roswell Park, who with Dr. Edward McGuire, is making a short tour of Great Britain, later will attend the International Surgical Association at Brussels.——Drs. Matthew S. Mann and Herbert W. Williams are on a fishing trip in Canada.

Moving Day for Insane.—Fifty insane women, who are charity patients at Long Island State Hospital, were taken on August 22 to the Willard Parker State Hospital at Ovid, N. Y. They are the first of 400 charity patients housed in the building now to be turned into the King's County Hospital to be transferred. The others will soon be sent to the Rochester and Willard institutions.

Eddyite Cases.—The health department refused to issue a burial permit in the case of Thomas A. Chilcott, who died without medical attendance, but who was treated by Eddyites. On investigation it was shown that his case was hopeless, because he died from diabetes and diabetic gangrene. At the request of the Erie County Medical Society the district attorney is investigating the death of Mason Griffin, 2 years old, who was treated by Eddyite healers. It is charged that an irregular death certificate, signed by a doctor who had not been in attendance, was granted, and that the boy died as the result of pertussis, a contagious disease which should be reported to the health department. By order of the district attorney the body is to be exhumed and the medical examiners will hold an examination.

New York City.

Personal.—Drs. William T. Bull, William B. Coley and Walter F. Chappell returned from Europe on the *Kronprinz Wilhelm*, August 23.

Detained at Hoffman Island.—Nine cabin passengers and six of the crew of the steamship *Finance*, from Colon, have been held for further observation on account of high temperatures.

The Brooklyn Theaters Closed.—There has been some complaint that the health board has acted in a high-handed manner in closing the Brooklyn theaters and condemning them as insanitary and dangerous. A statement has been given out at the headquarters of the Health Department that owners have been twice notified since April that they would have to comply with the law and that the complaints are unjustifiable.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended August 19, 464 cases of tuberculosis, with 115 deaths; 252 cases of typhoid fever, with 25 deaths; 119 cases of measles, with 5 deaths; 117 cases of diphtheria, with 19 deaths; 41 cases of scarlet fever, with 3 deaths; 16 cases of cerebrospinal meningitis, with 16 deaths, and 14 cases of varicella.

Typhoid Fever on the Decline.—The figures presented day by day show a steady decline in the number of typhoid fever cases. Only 22 new cases were reported in Brooklyn from August 19 to August 23. In the same time there were 13 new cases reported in Manhattan and none in the other boroughs. Last year the climax was reached in the week ending August 27, when 82 cases were reported. The number of cases for the corresponding week this year was 252.

Richmond Waterless.—An opinion was filed on August 21 sustaining the constitutionality of the act passed by the New Jersey legislature prohibiting the diversion of potable water in New Jersey to other states. This decision will greatly disappoint Staten Island, which looked to New Jersey to supplement its painfully scant natural supply. In view of the recent scarcity of water in this locality the problem of securing a sufficient supply is serious and the necessity imperative.

PENNSYLVANIA.

Personal.—Dr. James M. Anders, Philadelphia, has returned from his trip to Alaska.

Sanitary Engineer Selected.—Dr. Samuel G. Dixon, state health commissioner, on August 25 appointed F. Herbert Snow, Boston, Mass., chief of the sanitary engineering division of the State Health Department, August 25.

Illegal Practitioner Arrested.—The United States postal authorities have started a crusade to rid Philadelphia of quacks and illegal practitioners who advertise illegal remedies and through the mails suggest illegal operations. Four persons were arrested on this charge August 21 and held, one in $1,000 and three in $800 bail each. The law makes it a criminal offense to suggest by letter where illegal medical advice may be obtained. Besides the four arrests thus far made, convicting evidence has been obtained against several other persons. Since the crusade began many of the malpractitioners have left the city.

Philadelphia Health Report.—The total number of deaths reported for the week ended August 26 aggregated 438. This is the same number as reported last week, and the week before. Such a coincidence has never been known by the local authorities. The health of the city remains good and there is a decrease in contagious diseases. The principal causes of death: Typhoid fever, 10; consumption, 41; pertussis, 5; diphtheria, 5; cancer, 12; apoplexy, 23; heart disease, 35; acute respiratory diseases, 25; enteritis (under 2 years), 59; enteritis (over 2 years), 13; Bright's disease, 39; general debility, 25; marasmus, 17, and injuries and accidents, 8.

No Temporary License.—It is not an uncommon practice for a physician to place in charge of his practice one who *is not* regularly licensed according to the act of assembly governing the practice of medicine in this state. Dr. Henry Beates asserts that the impression seems to prevail that such an appointment is not an infraction of the law. To show that such practice is illegal Dr. Beates has secured an official opinion from the attorney general concerning the subject, which is in part as follows:

> In my judgment this is not in accordance with the Medical Practice Act, which prevents one from opening an office and regularly establishing himself as a practitioner of medicine without having first qualified according to the statute. Duties of this character, requiring special qualifications and subject to government control as a part of the police power of the state, can not be assigned to unqualified persons. The mere fact that the assignment may last but a brief period does not alter the legal aspect of the case. The maxim of the law is *qui facit per alium facit per se*, and the agent in a matter of this sort must have the qualifications of the principal. I see nothing whatever in the law to prevent one qualified practitioner from calling on another qualified practitioner to take charge of his practice during his absence, but there is nothing whatever in the law which permits the substitution for a trained and duly qualified professional man of one who has not complied with the statute, and who, therefore, is not qualified to practice.

WISCONSIN.

Personal.—Dr. Wilbur T. Sarles, Sparta, sailed from Europe September 1.——Dr. Soren Sorenson, Racine, has been appointed head physician of the United Danish Societies of America.——Dr. Henry P. Rhode has been made health commissioner of Green Bay, vice Dr. Francis P. Thibido, who resigned after six years' service.——Dr. Henry L. Barnes, health officer of Ripon, has resigned.

Commissions on Prescriptions.—Dr. Edward A. Taylor, Racine, who was sued by a druggist for a drug bill of $70, which he refused to pay, claiming, it is alleged, that the druggist owed him $200 for business sent by him, was defeated on trial, the judge holding that contracts between physicians and druggists whereby the former receive commissions for sending prescriptions to the latter, are void and that such practices are contrary to public interest.

Must Make Reports.—The State Board of Health has issued a leaflet setting forth the law requiring reports of births, deaths and accidents. The following is a summary:

> The law provides that every attending physician practicing in this state shall report all births, deaths and accidents occurring under his jurisdiction within thirty days from the time of the occurrence.
>
> In cities *births* must be reported to the health officer.
>
> In cities *deaths* must be reported to the health officer.
>
> In cities *accidents* must be reported to the health officer.
>
> In towns and villages births must be reported to the village or town clerk; deaths must be reported to the village or town clerk; accidents must be reported to the village or town clerk. In all cases of death under your professional care you are required to certify to the health officer of cities and to the town or village clerk of towns or villages, the primary and secondary cause of death. The law requires that this shall be done before the burial permit can be issued.
>
> Fees for reporting births, deaths and accidents as above, 25 cents in each case, to be paid by the county in which they occur.

GENERAL.

Cholera in Manila.—A cable from Manila, dated August 25, states that there is an outbreak or cholera in Manila and that several natives and one American woman have died from the disease.

Tri-State Medical Society.—The seventeenth annual meeting of the Tri-State Medical Society of Alabama, Georgia and Tennessee will be held in Chattanooga, Tenn., September 26-28. The secretary is Dr. Raymond Wallace, Chattanooga, Tenn.

Health of Panama.—Acting Assistant Surgeon Mohr of the Public Health and Marine-Hospital Service reports that during July the deaths from all causes officially reported in the municipalities of Colon and Cristal was 72, excluding still births. Malarial fever has been very prevalent among the negroes and natives and is no doubt responsible for a large number of deaths. Recently large numbers of native Colombians have been brought to the Isthmus as contract laborers, and those who come from the interior of Colombia seem to be peculiarly susceptible to both malaria and yellow fever.

Health of Panama Canal Zone.—The June report of Col. F. C. Gorgas, chief sanitary officer, shows that while June, 1905, was not unusually salubrious in the city of Panama, there was nothing extraordinary in its death rate, either as compared with former Junes in the last 22 years or with other months in the last year. On the last of June over 10,000 laborers were on the government rolls. Of this number there were sick every day, on an average, 274, or 27 per thousand, a sick-rate which compares favorably with that of a similar body of laborers anywhere. Twenty-four persons died from all causes. This, if continued for the year, will give a death rate of 28.8 per thousand. In 1881, the first year of the French occupancy of the canal, the death-rate was 67 per thousand, with 11 deaths from yellow fever, a rate of 12 per thousand. During June, 1905, there were only 14 deaths from yellow fever, a rate of 3 per thousand. On the entire isthmus during the month, in a population of about 50,000 people, there were 61 cases of yellow fever with 18 deaths, a rate of about 25 per cent. Of these 61 cases, 30 were employes of the commission, of whom 4 died, a rate of about 14 per cent. Among this number were 15 Americans brought from the United States by the commission. Of these 15 one died. This difference in mortality is ascribed to the fact that the American is, on the average, in the prime of life, and in first rate condition, reports to the hospital as soon as he feels sick, and thus places himself in the best possible condition for recovery. Among the non-employes of the canal, there were 27 cases, of whom 13 died, nearly 50 per cent. These persons usually apply for treatment when they are beyond the possibility of deriving any benefit from it. One case of plague occurred at La Poca, the Pacific terminus of the canal, in the person of a negro laborer, a longshoreman who probably was infected through a cargo coming from some one of the infected ports to the south. A strict quarantine was at once established, and a rat crusade commenced. Only one infected rat was found and no other case occurred. The report also includes a detailed review of the sanitary measures carried out by the commission of the city of Panama in the way of street and yard cleaning, garbage collection, fumigating and yellow fever prophylaxis. The city has been divided into districts, each in charge of a physician who makes a house to house inspection in order that all yellow fever suspects may be isolated and screened at once. The organization of a brigade of rat-killers is also in progress.

THE YELLOW FEVER SITUATION.

CONDITION SEEMS BETTER, BUT GREAT ALARM STILL EXISTS—SYSTEMATIZED INSPECTION BEING ESTABLISHED.

Latest Reports.

Amelioration.—As we go to press fresh news comes from all parts of the stricken region. New Orleans reports that Dr. John Archinard, attached to the Emergency Hospital, believes he has found the germ of yellow fever—an organism resembling the malarial parasite.——Conditions in the city continuing to improve, Surgeon White contemplates the transfer of some of his force to the country, where the cases increase.——Leeville is the worst afflicted locality, but with outside help some improvement is seen.——Allegation comes that the cases at Gulfport, Miss., were deliberately concealed by a diagnosis of malaria to avoid quarantine difficulties. According to the story of the Gulfport woman, who fell ill of the disease on the way to New Orleans, and whose attack led to the discovery of the other cases, some patients in Gulfport had been under physicians' care for fourteen days before she left.——It is reported that Dr. Fitchette, health officer of Natchez, refuses to accept the diagnosis of the county health officer of the presence of yellow fever cases in that town. Surgeon Young, by special train, went from Jackson to Natchez to see the cases.——Alabama has quartined against Natchez.——Texas has applied its quarantine to Memphis and to all of Mississippi.——Lunnenburg County, Virginia, reports a possible death from yellow fever.

The Record to August 30.—New deaths, August 29, 7; total deaths to date, 293; new cases, 80; total cases to date, 2,133; new subfoci, 9; total subfoci to date, 439.

Louisiana.

Record of Cases.—In New Orleans the epidemic record to August 27 was as follows:

New cases reported August 26	31
Deaths reported August 26	13
Total number of cases to August 26	1,755
Total deaths to August 26	260
Death rate of epidemic	14.8 per cent.
New foci of infection	12
Total subfoci to date	390

The reports for the week show a decreasing number of cases, but, toward the end of the week, a rise in the number of deaths. The epidemic in the city appears to be fully under control.——As showing the average health conditions of New Orleans the Board of Health has published the following figures:

Years.	Number of deaths.	Population.	—Death rate per 1,000 per annum.—		
			White.	Colored.	Total.
1899	7,893	300,000	23.39	33.11	26.31
1900	7,424	300,000	20.56	34.44	24.74
1901	6,478	305,000	18.06	29.70	21.24
1902	6,572	310,000	17.91	30.18	21.20
1903	6,705	317,000	18.02	29.82	21.15
1904	6,819	325,000	17.66	30.19	20.98

Between 1879 and 1900 there were 407 deaths from yellow fever. The greatest number of deaths from that disease occurred in 1897, when 298 victims succumbed. There were no deaths from the pest in ten years of that period, and there were none in 1900-1903.——President Charles Janvier of the citizens' committee set a splendid example when arrested for failure to screen his cistern. He explained that he had oiled it, thinking that more effective. Naturally he was set free, but on hearing some adverse criticism he asked to be re-arraigned and fined, which was done.——An unfortunate controversy is being waged between some members of the profession on one side and the Louisiana Board of Health and New Orleans Board of Health on the other. There is talk that the executive officer of each board will be asked to resign. The subject of the controversy is the concealment of the early cases.——In an interview Dr. John Guiteras of Havana said that it was hardly to be expected that the infection could be stamped out before frost. It was under control, but had gone too far to exterminate. He predicted that this was the last epidemic of yellow fever that would ever appear in the United States. In a later interview he predicted that the disease would be stamped out before frost, as the situation has become distinctly better.——At a mass meeting on August 23, called by Dr. Leach of arsenic fame, 300 people denounced the press, the physicians and all health officials, and promised to continue doping with arsenic. This shows clearly that Dr. Leach's presence in New Orleans at this time is wholly harmful and that his desire for notoriety is decidedly uppermost among his motives.——One case discovered August 26 was a patient recently arrived from Gulfport, Miss. Following this up, the authorities found three existing but unreported cases at Gulfport.——The public schools will not open until October 2.——Leeville on August 23 reported 177 cases of yellow fever and 200 cases of dengue.——Arrangements have been made for a drastic campaign of extermination against the disease at the various infected points throughout the state.——On August 29 35 new cases of fever were discovered in Bayou Barataria, Jefferson parish. The tour of investigation had not then been completed. Deaths had occurred and there were neither physicians nor nurses. A relief party was organized at once with physicians, nurses, medicines and supplies to assume charge of the situation.

Other States.

Arkansas.—The State Board of Health on August 21 quarantined against the entire state of Louisiana.

Illinois.—At the end of one week of train inspection at Cairo it is reported that 1,000 passengers had been inspected and 2,000 health certificates issued, seven physicians being kept busy.——Inspectors of the United States Public Health and Marine-Hospital Service have been traveling on trains running from Louisiana and Mississipi to Cairo. On August 23 Dr. Egan, secretary of the Illinois Board of Health, ordered this stopped. Dr. Egan later amended the order to admit such federal inspectors as are yellow fever immunes.——Brownsville on August 23 reported a case of yellow fever from Shreveport, La., but this was later announced as a false report.

Indiana.—Jeffersonville on August 17 had a yellow fever scare regarding the towboat *Sprague*, which was thought to be infected, having had illness on board since it left New Orleans. The health authorities ordered the boat to proceed to its destination, Cincinnati, on pain of the crew's incarceration in the pest house.——The Crawfordsville case, when seen by Dr. A. M. Brighton of Indianapolis, proved to be acute malarial fever.——Dr. Nelson W. Brayton, of the Indianapolis health office and son of Dr. A. H. Brayton, is in New Orleans studying yellow fever.——Michigan City had a small scare in the shape of an acute illness of a woman recently arrived from Arkansas.——Evansville had a supposititious case of yellow fever, but the attending physician and health officer agreed in a diagnosis of typhoid.

Kentucky.—Paducah says that if the State Board of Health persists in refusing permission to quarantine, the City Council will pass a quarantine ordinance in defiance of the board. The town has a new board of health with Dr. S. H. Brothers as president. The dispatch adds: "The old board was against a quarantine."——Jackson, Tenn., has a quarantine against Fulton, Ky., that is very annoying to the latter town.——Members of the board of health of Paducah have been charged by reliable eye-witnesses with selling certificates of health without embarrassing questions to all-comers at $1 each.——Dr. A. T. McCormack, assistant secretary of the State Board of Health addressed the City Council of Paducah, arguing against a quarantine.——The state board issued an order forbidding the Illinois train inspectors to continue their practice of discharging on Kentucky soil all passengers not admissible to Illinois.——Louisville had a small scare over a suspicious case which proved not to be yellow fever.——The city council of Henderson refused to appropriate any money for the board of health to use in preparing the city for possible infection.——The latest word from Paducah is to the effect that every one there, the physicians and board of health excepted, desires a quarantine.

Michigan.—A case of yellow fever was reported at Crockery, Ottawa County, the patient being a man just arrived from New Orleans.

Mississippi.—The early cases of yellow fever at Mississippi City were so light that the physicians mistook them for malaria, so for nearly a month the focus was unrecognized. Of course Governor Vardaman threatened the "extreme penalty" for these physicians if neglect of duty on their part could be proved. Credit for discovery of the case is claimed for Dr. Sanders and others of a party of Alabama health authorities who were making an inspection tour of the Gulf coast of Mississippi. The stegomyia was also found in large numbers.——Most of the remainder of Mississippi has quarantined against its gulf coast towns.——Vicksburg has raised its absolute quarantine against Memphis.——Secretary Hunter of the Mississippi board of health has asked physicians to form local health associations in every county and to hold daily meetings for the discussion of suspicious cases.——Natchez, which "has been tightly bottled up with a shotgun quarantine ever since the infection of New Orleans was reported," on August 26, admitted that it had nine undoubted cases of yellow fever and three cases of suspicious illness. The news caused a panic and the pressure to escape from the city became tremendous. The Marine Hospital Service arranged for special through trains for the north for all who wished to leave and anticipated the departure within 24 hours of fully 2,000 persons.——Gulfport, on August 27, reported three new cases of yellow fever, having already during the week admitted the existence of three other cases.——Jackson, with neighboring towns and counties, has quarantined against Memphis, because a woman just arrived in New Orleans from Memphis, developed the disease.——Mississippi City has been placed under martial law by Governor Vardaman.

Missouri.—The case of yellow fever at Gregory, on the Mississippi River just below Keokuk, proved fatal. The patient was a Greek, said to have come to Gregory from Natchez, Miss. Boats touching at Gregory are not permitted to land in Keokuk.

Ohio.—It was attempted to create some excitement in Cincinnati last week over the approach up the Ohio River of the steamers *Sprague* and *J. B. Finley*, both reported to have yellow fever aboard.

Tennessee.—Search for the stegomyia at Chattanooga is reported to have demonstrated its absence at present.——Memphis reports local railway passenger business at a standstill, while through traffic keeps up pretty well.—On August 22 the Chattanooga quarantine was made still more stringent.

Texas.—A detention camp has been established on Red River for the protection of north Texas.——Orange asked that passenger traffic with Louisiana be forbidden. Here and elsewhere objection is made to the expense of detention camps, it being alleged that Louisiana at its borders should bear the detention expense of its outgoing citizens.——Galveston has been undergoing the most thorough cleaning that it has had in years, if ever.——At San Antonio $3,000 was subscribed by ward canvass and forwarded to the state health officer to aid in the quarantine work for which there is an utterly inadequate appropriation.

CANADA.

Tuberculosis Sanitarium for New Brunswick.—Physicians of New Brunswick are reported to be making an effort to obtain a sanitarium for consumptives. The St. John Medical Society has appointed a committee to collect information and to bring the subject properly before the people. It is hoped that the government will act in the matter at an early date.

FOREIGN.

Plague in the Argentine Republic.—A report from Buenos Ayres states that six cases of plague were discovered recently in Tucman.

Typhoid Fever in New Zealand.—It is reported that there have been a number of outbreaks of typhoid fever among the Maori settlements in North Island.

Typhus Fever in Ireland.—An alarming outbreak of typhus fever is reported from Donegal. Nine families have been attacked and one death is reported. The "contacts" have been isolated.

The Birth Rate in New South Wales.—According to the government statistician's report for June, 1,246 children were born in this province during the month. The excess of births over deaths was 785.

Jenner Memorial Tablet.—On August 9 the London County Council erected a tablet on the house in which Edward Jenner, the discoverer of vaccination, lived during 1803. The tablet is of green encaustic ware.

Yellow Fever in Brazil.—Acting Assistant-Surgeon Stewart reports that yellow fever is prevalent in Para. An Italian opera company there has lost so many members that it will probably be forced to disband.

Plague in Japan.—It is reported that, after a period of quiescence, plague has again made its appearance in Tokio and that the disease seems to be spreading in spite of the rigid quarantine which is enforced.

Asiatic Cholera in Prussia.—A report from Dantzig states that two Russians recently died in Culm, West Prussia, of a disease which was diagnosed as Asiatic cholera. The authorities declare that there is no danger of the disease spreading.

Medical Bequests by Physicians.—THE JOURNAL has chronicled lately a number of bequests by physicians for medical purposes. The latest is from Dr. Toporski of Posen, who left $200 to the local fund for conducting the campaign against tuberculosis.

Reduction of Rates on French Railroads for Members of Tuberculosis Congress.—It is officially announced that membership in the International Antituberculosis Congress, to be held at Paris, October 2-7, entitles one to a reduction of 50 per cent. on the railroads in France.

Second International Milk Congress.—This congress will convene at Berlin October 16-19, and will represent every phase of the milk question. There are to be six sections, one devoted exclusively to legislative measures in regard to the production, distribution, etc., of milk.

Public Disinfecting Plant for Tasmania.—The Tasmania local board of health held a conference June 28 to consider the question of erecting a public disinfecting plant in accordance with the suggestions of the health officer, Dr. Elkington. It is estimated that the capital cost of such a plant would be about $5,000.

Garre Goes to Breslau.—Karl Garré, professor of surgery at Königsberg, has accepted a call to the chair of surgery at Breslau left vacant by the death of Mikulicz. Garré was born Dec. 12, 1857, and is thus in his forty-ninth year. His works on surgery of the nerves, vessels, larynx and alimentary canal have been especially noteworthy.

Celebration of Lucae's Seventieth Birthday.—The present and former assistants of Prof. August Lucae of Berlin presented him with a *Festschrift* in honor of his seventieth birthday, August 24. The famous otologist also received many messages and telegrams of congratulations from friends and scientific bodies at home and abroad.

Smallpox in Chili.—It is reported that there is a severe outbreak of smallpox at Santiago. According to *Public Health Reports*, this is not anything unusual and is probably only a recrudescence of a disease which is always present there and is due doubtless to the cold weather which has been prevalent recently in South America.

Tests of Sight and Hearing for Government Employes.—The German department of public works has ordered that every employé throughout the department is to be tested for vision and hearing in the course of the next five years. Those found defective are to be transferred to posts of lesser responsibility or pensioned out of the service.

Physicians Must Write Legibly.—The authorities in the duchy of Hesse, Germany, have notified druggists throughout the country that when a physician's prescription is written illegibly—as frequently happens—the druggist is not to waste any time guessing at the writer's meaning, but to require from the physician a legible copy or indication of the contents.

Jubilee of the University of Melbourne.—The University of Melbourne attains its jubilee next year and preparations are already in progress to celebrate the event. It has been proposed to erect a pavilion on the cricket ground as a suitable memorial and a committee has been appointed to secure funds. It has been estimated that about $4,000 will be necessary, and of that amount about $2,000 has been promised.

Warning Against Massage and Hypodermics by Irregulars.—The Board of Public Health at Rome has issued a notice warning the public against the dangers of massage, hypodermic injections and operations of any kind by only partially qualified persons, such as nurses, midwives and others. It seems that such practices are becoming prevalent in these circles, and the public is warned of the possible danger in incompetent hands.

Prize for Work on Trachoma.—THE JOURNAL announced some time ago that the government of Hungary had offered a prize of about $500 for the best work offered in competition on the subject of trachoma. The prize was divided and half given to Professor Kuhnt of Königsberg for his essay on the subject of treatment of trachoma. The other half of the prize was not awarded, as no suitable articles on the pathology of the disease were received.

Suggestion for Prize for Remedy for Tuberculosis.—One of the members of the Brazilian parliament recently urged the adoption of a resolution endowing a prize of over a million dollars, to be awarded to anyone discovering a sovereign remedy for tuberculosis. It will be remembered that the French *Académie de Médecine* has an endowment representing an annual income of several thousand dollars, which is awaiting the discoverer of such a remedy.

The Brisbane Hospital.—The financial condition of the Brisbane Hospital is reported to have been very unsatisfactory for some time. At the end of June the executive committee found themselves without funds and in debt for a large sum for current expenses, besides the amount due the government as interest on a loan of $15,000. Finding themselves in this position the members of the committee decided to resign in a body, and the resignations were handed to the home secretary July 10.

New York's Board of Public Health from the German Point of View.—One of the meetings of the Berlin Medical Society this summer was given up to a description of the scope and workings of the New York Board of Health. The speaker was Prof. A. Wassermann, and he drew a very complimentary picture of the great work accomplished by the board, contrasting it with the apathy displayed by the city authorities of Berlin, who, he stated, are far behind the times in the matter of municipal protection of the public health.

A Medical Prince and the Wily Irregular.—A certain Grundlach of Munich recently published a pamphlet denouncing mercurial treatment of syphilis. He represented to Prince Ludwig Ferdinand of Bavaria, who is a registered and practicing physician there, that certain of the medical authorities, citing them by name, indorsed his views. On this representation the prince wrote a complimentary preface to the work. The local medical society at once interviewed the prince, who has since publicly retracted his statements, explaining that they were obtained under false pretenses.

Decline of Cholera in Russia.—The *St. Petersburg med. Wochft.* for August 5 states that it has been officially announced that not a single case of cholera has been known to occur in Russia since April. The suspicious cases at Lodz, Wilna, Tomsk and elsewhere proved to be some other disease on microscopic examination or on the evidence of the course of the disease or the postmortem findings. Sanitary precautions are still maintained along the frontier, but the local campaigns inaugurated at various points have been suspended and the physicians recalled to their posts.

Mortality Among Physicians.—The *Deutsche med. Wochft.* summarizes in a recent issue the article published in The Journal on "The Mortality of American Physicians." It cites in addition the average length of life among the physicians of France as 64.75 years. In the northern regions the average was only 58.3, while it reached nearly 71 in the Albi and Gaillac districts. An unusually large proportion of the medical men of France are now in the seventies. Only one French physician in the last two centuries lived to be over 100, and only 2.16 per cent. passed the ninety mark.

Quinin Prophylaxis of Malaria in Italy.—The *Riforma Medica* for July 22 states that at the last official conference of the Society for the Study of Malaria, Professor Celli related that the number of persons "prophylaxized" with quinin in the Roman district has increased from 1,175 to 30,000 in the last three years, while the number of cases of malaria treated in the hospitals has decreased from 6,000 to less than 3,000 during this time. In the Italian army the morbidity from malaria has dropped from 67 to 10 per cent., and among the railway employes from 69 to 33 per cent. The general mortality has fallen from 13,000 to 7,000 since the legislation was adopted providing free quinin for the people.

Chair of Protozoology in the University of London.—A chair of protozoology has been founded in the University of London. The secretary of state for the colonies offered the university a sum of $35,000 for the establishment of the chair. The *British Medical Journal* states that of this amount $1,000 is a contribution from the Rhodes trustees and that $25,000 represents a moiety of a grant originally made from the Tropical Diseases Research Fund to the Royal Society for the Promotion of Research Work, and surrendered by that society for the purpose of establishing this chair in the university. The university senate has decided to devote the whole amount to defraying the salary of a professor and to set aside a further sum of $1,000 a year for assistants and laboratory expenses.

Organization of the Profession in Germany.—The conflict between the sickness insurance companies and their medical officers over the demand of the latter for increased remuneration when the period of treatment was doubled in length, has been chronicled again and again in these columns. One of the few places where the physicians were supposed to have lost the battle was at Mülheim, where the companies imported enough "strike breakers" to answer their purpose and ignored their former medical officers completely. Time has shown, however, that the medical men willing to serve as strike breakers were below the standard of scientific acquirements required for the positions. One by one they have had to be dismissed and the terms of the former medical officers accepted, followed by their reinstatement.

Political Attitude of Physicians in Russia.—We learn that the editor of the Journal of the National Pirogoff Association, Dr. Popoff, has been held responsible for the revolutionary resolutions passed at the last conference and mentioned in The Journal at the time. The publication was suspended by the authorities and the editor placed under surveillance. The collaborators on the publication and more than fifty of the physicians of Moscow have since voluntarily proceeded to the authorities and announced that they share the views of the editor-in-chief, that they assume equal responsibility with him for the resolutions adopted and for the transactions and comments published in the journal. An all-Russian congress of odontology was recently held at St. Petersburg, and seventy of the members also publicly proclaimed their unqualified endorsement of the revolutionary resolutions passed by the Pirogoff congress.

Sanatoria for Lung Affections in Germany.—The rapid growth of the sanatorium movement in Germany is seen by the statistics recently published There were only three in 1892, and only 13 as late as 1897, while now there are 68 official and 27 private institutions of the kind. The Red Cross took the lead in the movement, but was soon seconded by the societies insuring against sickness. The latter devoted special attention to the curable cases of pulmonary affections, and 11 of these regional sickness insurance societies now have sanatoria of their own, as also a number of cities and communities, including Berlin, Leipsic, Saarbrucken and Wittich. The sanatorium movement was the logical consequence of the compulsory insurance of wage-earners against sickness. The education in hygiene acquired by those taking a course at a sanatorium and sown abroad by them afterward throughout their environment is one of the greatest benefits of the movement.

Infectious Diseases in Australia.—Though scarlet fever was considerably less prevalent in Sydney in 1904 than in 1903, the incidence continued high, and amounted to 2.4 per 1,000 of the estimated population. The recorded monthly number of attacks showed very little fluctuation until August, when it began to rise, reached a maximum of 188 in October, and thereafter fell to 136 in December; 530 males were attacked, as against 831 females. Between December 8 and 24 a localized outbreak of scarlet fever, numbering 23 cases, occurred in adjoining portions of the three contiguous boroughs of Ashfield, Burwood and Drummoyne. This was confined to the customers of a dairy situated in Drummoyne. The outbreak was less sudden in its manifestation than is usually the case with milk epidemics. Fourteen deaths occurred from scarlet fever, corresponding to a mortality of 0.02 per 1,000 of the estimated population of the metropolis. This death rate is the lowest recorded since the year 1900. The case fatality equaled 1.03 per cent. of notified cases, and is lower than that of any year since 1898. More attacks of diphtheria were notified than in any previous year. The number of reported cases was 738, which is equal to an attack rate of 1.43 per 1,000 of the estimated population.

Correspondence

Cats as a Factor in the Propagation of Infectious Diseases.

Worcester, Mass., Aug. 2, 1905.

To the Editor:—A research study is being made at Clark University in reference to the possible causal relation of cats as a factor in propagating infectious diseases, especially those of children.

I wish to make an appeal through your columns to the readers of The Journal who have observed any communication of disease from cats to human beings and to ask them kindly to put me in possession of such facts. This would aid materially in deciding to what extent the cat may be a source of danger in the transmission of communicable diseases.

C. A. Osborne, M.D.

Association News

Next Annual Session.

The next annual session of the American Medical Association will be held in Boston, Mass., June 5 to 8, 1906.

The Card Index and Directory.

Two weeks ago we printed in our advertising pages a blank for information for the Biographical Card Index and for the American Medical Directory. While many have filled out and returned this blank, the number who did so is comparatively few. We include the blank in our advertising pages this week—see page 31—and hope those who have not already done so will fill in the blank, and return it at once. The more cooperation we get in this work the less expense will be attached to it. The ultimate object is not a commercial one, but the good of the profession. It should be understood that the information asked for is primarily for the Biographical Card Index; only a portion will be used for the directory.

Marriages

Sandy B. Harrell, M.D., Nashville, Tenn., to Miss Eva Stockdell, at Atlanta, Ga.

Charles F. Voyles, M.D., Murdock, Ill., to Miss Hazel Wagner of Newman, Ill., August 16.

Charles Gordon Abell, M.D., to Miss Grace Fish, both of Enosburgh Falls, Vt., August 30.

Willard C. Selover, M.D., to Miss Minnie Carson Hill, both of Stanley, N. Y., August 16.

Willard Earl Quillian, M.D., Atlanta, Ga., to Miss Laurie May Cassilly of St. Louis, August 15.

John Steele Sweeney, M.D., Chicago, to Miss Grace Hamilton of Two Rivers, Wis., August 16.

Walter E. Murphy, M.D., Cincinnati, to Miss Mathilde Calhoun of Covington, Ky., August 22.

William N. Stein, M.D., Shanandoah, Pa., to Miss Maggie D. Martin of Blair Hill, Coatsbridge, Scotland, August 23.

Deaths

Jared E. Cone, M.D. State University of Iowa Medical Department, Iowa City, 1882, a member of the American Medical Association, Ohio State Medical Society, Ohio Pediatric Society, treasurer and former president of the Mahoning County Medical Society; coroner of Brule County, S. D., from 1883 to 1886; surgeon to the Mahoning Valley Hospital; one of the most prominent practitioners of Youngstown, Ohio, died at the Mahoning Valley Hospital August 24, from rheumatic endocarditis, after an illness of four weeks, aged 55.

Marcellus H. Felt, M.D. Dartmouth Medical School, Hanover, N. H., 1877, treasurer of the New Hampshire Medical Society for fifteen years and last year its president; a member of the Hillsboro Bridge school board for twenty years; representative in the legislature in 1893 and 1894; state senator in 1902; medical referee for the district, died at his home in Hillsboro Bridge, August 21, aged 60.

Charles H. Andrus, M.D. College of Physicians and Surgeons in the City of New York, 1845, surgeon of the One Hundred and Twenty-Eighth New York Volunteer Infantry, and brigade surgeon in the Civil War; coroner of Dutchess County, N. Y., in 1871; for many years a practitioner of Poughkeepsie, died at the home of his son in Enfield, Mass., August 12, aged 82.

Will Rininger, M.D. Marion-Sims College of Medicine, St. Louis, 1899, a member of the American Medical Association and the St. Louis Medical Society; assistant professor of nervous diseases and internal medicine in the Marion-Sims-Beaumont College of Medicine, St. Louis, and a young man of bright promise, was fatally burned by an explosion of benzine at his home, August 22, and died forty-five minutes later, aged 31.

Franklin Gillespie, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1889, of Oxford, Pa., a member of the American Medical Association, was struck by a train at Barnsley, Pa., while making a professional call, August 23, and died a few hours later, as he was being carried into his house, aged 45.

Robert W. Hinds, M.D. Vanderbilt University Medical Department, Nashville, Tenn., 1902, assistant city bacteriologist and chemist of Atlanta, Ga., and assistant secretary of the State Board of Health, died at his home in Atlanta August 18, from typhoid fever, after an illness of six weeks, aged 26.

William D. Nutter, M.D. University of Vermont Medical Department, Burlington, 1887, of Malden, Mass., and city physician from 1892 to 1895, died on Bustin's Island, Casco Bay, Maine, August 18, after an illness of nearly three years, from diabetes, aged 45.

James Henry Salisbury, M.D. Albany (N. Y.) Medical College, 1850, an early research worker on the germ theory of disease, died at his country home in Dobbs' Ferry, N. Y., August 28, from cerebral hemorrhage, after an illness of four years, aged 81.

John S. Morey, Jr., M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1877, some-time postmaster of Royersford, Pa., died at his home in that place August 18, after a long illness, from cerebral hemorrhage, aged 59.

Joseph Plumb Cochran, M.D. College of Physicians and Surgeons in the City of New York, 1877, a native of Oroomiah, Persia, who built the first hospital in Persia, died recently at his home in Oroomiah, from typhoid fever, aged 50.

Joseph Baldwin Amos, M.D. University of Maryland School of Medicine, Baltimore, 1854, one of the oldest practitioners of Pennsylvania, died at his home in Chanceford, York County, Pa., August 20, after a prolonged illness, aged 79.

John A. Morton, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1862, assistant surgeon of the Twenty-fourth Maine Volunteer Infantry during the Civil War, died at his home in Bethel, Maine, August 17, aged 71.

George B. Nichols, M.D. Castleton, (Vt.) Medical College, 1852, said to have been the oldest practitioner in Allegan County, Mich., died at his home in Martin, Mich., August 15, after an illness of several weeks, aged 72.

Edward Erskine, M.D. Michigan College of Medicine and Surgery, Detroit, 1891, a member of the American Medical Association, and an old resident of Rogers City, Mich., died at his home in that city, August 12.

Charles W. Fordyce, M.D. College of Medicine University of Southern California, Los Angeles, 1905, an interne in the German Hospital, Los Angeles, was drowned while swimming in the Kern River, August 20.

S. B. Hotchkiss, M.D. Bellevue Hospital Medical College, New York City, 1871, who had been an invalid for seven years, died suddenly at his home in Edinboro, Pa., August 16, from angina pectoris, aged 63.

Jacob W. Mooar, M.D. Dartmouth Medical School, Hanover, N. H., 1862, surgeon during the Civil War and an old practitioner of East Manchester, N. H., died at the Elliott Hospital, Manchester, August 12.

Marion Wells Thomas, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898, a medical missionary, died at her station on Bahrein Island, Persian Gulf, recently, aged 31.

Charles E. Bushnell, M.D. University of Vermont Medical Department, Burlington, 1869, died at his home on Smith Hill, Winsted, Conn., August 19, from heart disease, after a long illness, aged 61.

John Gorin Harvey, M.D. University of Louisville (Ky.) Medical Department, 1862, died at his home in Blue Mound, Ill., August 16, from general debility, after an illness of one year, aged 66.

Henry W. Giles, M.D. Albany (N. Y.) Medical College, 1874, who never practiced medicine, but devoted himself to his profession of music, died at his home in Albany June 5, after a long illness.

John M. McGroth, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1858, of Philadelphia, surgeon during the Civil War, died at Delair, N. J., August 22, aged 71.

Edmund W. Holmes, M.D. Department of Medicine of the University of Pennsylvania, 1880, of Philadelphia, died suddenly from heart disease in a street car in that city, August 28.

Augustin S. Clark, M.D. Starling Medical College, Columbus, Ohio, 1860, one of the oldest physicians of Washington County, Ohio, died at his home in Beverly, August 18, aged 84.

Lorenzo Traver, M.D. Albany (N. Y.) Medical College, 1857, from 1861 to 1868 acting assistant surgeon, United States Navy, died recently at his home in Providence, R. I., aged 70.

Lewis W. McCawley, M.D. Barnes Medical College, St. Louis, 1900, of Kell, Ill., was drowned while fishing in the Little Wabash River near Clay City, August 17, aged 31.

Charles N. Frederick, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1865, of Valley Forge, Pa., died at Strafford, Pa., August 19, aged 66.

Sarah B. Fleming, M.D. College of Medicine, Syracuse (N. Y.) University, 1873, died at her home in Coronado, Cal., August 25, after a long illness, aged 74.

Louis Gustave Guibert de la Mache, M.D. Ohio Medical University, Columbus, 1903, died from articular rheumatism at his home in Arnold, W. Va., August 15.

Ferdinand S. Overfield, M.D. University of Heidelberg, Germany (Years of Practice, Illinois, 1887), died at his home in Brookville, Ill., August 16, aged 76.

Seth Grout, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, died suddenly at his home in Auburn, Kan., August 5, aged 72.

William J. Andrew, M.D. Manitoba Medical College, Winnipeg, 1903, of Winnipeg, died at the Winnipeg General Hospital, August 20, from scarlet fever.

William D. Pettus, M.D. University of Nashvile Medical Department, 1868, died at his home in Republic, Ala., August 14, after a lingering illness, aged 62.

David A. Baldwin, M.D. New York University, New York City, 1849, died at his home in Englewood, N. J., August 11, from senile debility, aged 79.

John Gray Hughes, M.D. Jefferson Medical College, Philadelphia, 1853, died at his home in Altoona, Pa., from heart disease, August 23, aged 77.

Edward W. Doty, M.D. Long Island College Hospital, Brooklyn, N. Y., 1886, formerly of Paterson, N. J., died in Dover, N. J., August 20, aged 49.

George M. Rice, M.D. Hospital College of Medicine, Louisville, 1894, died from tuberculosis at his home in Powersburg, Ky., August 20, aged 38.

Tilghman D. Koons, M.D. Pennsylvania, 1878, while despondent, shot and killed himself at his home in Philadelphia, August 22, aged 52.

John Ebeling, M.D. New York City, 1882, of New York City, died suddenly, August 20, while on his way to Pine Ridge, N. J.

Deaths Abroad.

K. Wernicke, M.D., one of the most prominent neurologists of the day, succumbed recently to the immediate consequences of a bicycle accident while on a tour in Thuringia, aged 57. His labors to supply a scientific foundation for psychiatry in the pathology of the brain have accumulated a wealth of data which will supply a field for research for many years to come. He was one of the principal creators of the modern anatomy of the brain, and was the originator, at 26, of the present conception of aphasia and its pathologic basis. Fuchs styles this "the first work that bridged the gap between mental disease and morbid processes in the brain." Wernicke was the first to describe the pupil reaction in hemianopsia and the processes in hemorrhagic polioencephalitis. He studied medicine at Breslau and was assistant to Neumann and Westphal for a time, was appointed professor at Breslau in 1890 and at Halle in 1904. History records that he was the first to locate a neoplasm in the brain and systematically proceed to order its removal. This was as long ago as in 1882, and he is thus said to be the founder of surgery of the brain.

P. Schech, M.D., professor of laryngology at Munich, died July 1, aged 60. He bequeathed $500 to the local endowment for the widows and orphans of physicians.

W. Flemming, M.D., professor of anatomy at Kiel, noted for his pioneer research on cell development and pathology, died at Kiel, August 5, aged 62.

B. Honsell, M.D., professor of surgery at Tübingen, died at Carlsruhe, July 22, after a long illness, aged 35.

E. Schonberg, M.D., professor of gynecology and pediatrics at Christiania, died July 20.

F. Fischer, M.D., professor of surgery at Strasburg, died July 9, aged 50.

L. D. Moussons, M.D., professor of gynecology at Bordeaux, died July 7.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Aug. 26, 1905:

Kennedy, James M., asst. surgeon, ordered to accompany 17th infantry from Presidio of San Francisco, to Fort McPherson, Ga., then return to his station.

Baker, Frank C., asst. surgeon, ordered to proceed with infantry team from Fort Sheridan, Ill., to Sea Girt, N. J., to take part in *national match*.

Krebs, Lloyd Le R., asst.-surgeon, assignment to duty in the United States Transport Service revoked.

Porter, Ralph S., asst.-surgeon, assigned to temporary duty as transport surgeon on the *Buford* during the next voyage to Manila, where he will report for assignment in compliance with orders heretofore issued.

Metcalfe, R. F., asst.-surgeon, assigned to temporary duty as surgeon on the *Buford* during the next voyage of that transport from Manila, P. I., to San Francisco, Cal., and on arrival at the latter place to report by telegraph to the Military Secretary of the Army for orders, as heretofore directed.

Boyer, Perry L., asst.-surgeon, granted one month and eight days leave of absence, with permission to apply for two months' extension.

Yost, John D., asst.-surgeon, advanced to rank of captain, to date from July 2, 1905.

Rutherford, H. H., asst.-surgeon, advanced to rank of captain, to date from Aug. 16, 1905.

Crabtree, Geo. H., asst.-surgeon, will make one visit per day from Fort Jay, N. Y., to Fort Wood, N. Y., during the illness of the surgeon at that post.

Kennedy, Jas. M., asst. surgeon, granted 30 days' leave of absence, to take effect on completion of duty with troops to Fort McPherson, Ga., with permission to apply for thirty days' extension.

Duncan, Wm. A., asst.-surgeon, relieved from duty at Fort Leavenworth, Kan., and ordered to Manila, P. I., for duty in Philippines Division.

Harris, Jesse R., asst.-surgeon, leave of absence further extended thirty days.

Carroll, James, asst.-surgeon, detailed to represent medical department of the Army at the thirty-third annual meeting of the American Public Health Association, to be held at Boston, Mass., Sept. 25 to 29, 1905.

Hansell, H. S., asst.-surgeon, ordered, on departure of Company B 9th Infantry from Pekin, China, to proceed to Manila, P. I., and report to commanding general, Philippines Division, for assignment to duty.

Shellenberger, James E., contract surgeon, granted leave of absence for one month.

Long, Charles J., dental surgeon, left Fort Snelling, Minn., on [illegible] one month and seven days.

[illegible], contract surgeon, departed from Vancouver [illegible] on three months' leave of absence.

[illegible] contract surgeon, will proceed from Vancouver Barracks, Washington, to Fort Walla Walla, Washington, for duty, to accompany headquarters band and Troops A, B and C, 4th Cavalry, to San Francisco, Cal., on completion of which he will return to his proper station.

Whitney, W., contract surgeon, left Columbus Barracks, Ohio, with detachment of recruits en route to Fort McDowell, Cal.

Stone, Frank P., dental surgeon, leave of absence extended seven days.

Slater, Ernest F., contract surgeon, left Fort Hancock, N. J., on leave of absence for seven days.

Girard, Joseph B., asst. surgeon general, ordered to proceed to Manila, P. I., for duty in Philippines Division.

Navy Changes.

Changes in the Medical Corps U. S. Navy for the week ending Aug. 26, 1905:

Peck, A. E., P. A. surgeon, commissioned P. A. surgeon with rank of lieutenant from March 27, 1904.

Russell, A. C. H., surgeon, detached from the *Newark* and ordered to the Bureau of Medicine and Surgery, Navy Department.

Stepp, J., P. A. surgeon, detached from the *Topeka* and ordered home to wait orders.

Wood, F., pharmacist, retired, detached from the Naval Medical School, Washington, D. C., and ordered home.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Aug. 23, 1905:

Stoner, J. B., surgeon, granted seven days' leave of absence from Aug. 9, 1905.

Stansfield, H. A., P. A. surgeon, directed to report at Bureau.

Stansfield, H. A., P. A. surgeon, granted leave of absence for one month, or so much thereof as may be necessary, on account of *sickness*.

Gustetter, A. L., acting assistant surgeon, granted leave of absence for ten days from Aug. 16, 1905.

Stevenson, J. W., acting assistant surgeon, directed to report at bureau for consultation.

Troxler, R. F., pharmacist, granted seven days' leave of absence from Aug. 16, 1905, under paragraph 191 of the regulations.

Hall, L. P., pharmacist, leave of absence for thirty days, *amended* to read twelve days from Aug. 4, 1905.

BOARD CONVENED.

Board to meet at San Francisco, Aug. 24, 1905, for physical examination of Engineer Maxwell, Revenue Cutter Service. P. A. Surgeon J. M. Holt, chairman. Acting Asst.-Surgeon A. Weeks, recorder.

Book Notices

First Aid for Persons Overcome by Gas. Cloth. Pp. 15. With 15 Illustrations. Philadelphia: United Gas Improvement Co.

This little booklet gives valuable instruction in caring for and resuscitating individuals overcome by gas. The methods of performing artificial respiration, etc., are shown by means of excellent illustrations. While primarily intended for the laity, it should be a valuable addition to the physician's library. For a gas company to issue such a book is distinctly to be commended, being in line with the discussion quoted in The Journal July 15, 1905, page 211.

Frames and Lenses. A Practical Treatise for Optometrists. Illustrated. By R. M. Lockwood. Paper. Pp. 87. New York: Frederick Boger Publishing Co.

This book describes the manufacture of lenses, the manner of surface polishing and of testing the uncut lenses. Two chapters are devoted to facial measurements and emphasis is laid on the importance of accuracy. The little book will interest any one who prescribes glasses.

Select Methods in Food Analysis. By Henry Leffmann, A.M., M.D., Ph.D., and William Beam, A.M., M.D., F.I.C. With 55 Illustrations. Second Edition. Revised and Enlarged. Cloth. Pp. 396. Price, $2.50 net. Philadelphia: P. Blakiston's Son & Co. 1905.

One of the most popular of the series of analytical books of Dr. Leffmann now in the second edition. Revised and brought up-to-date, having largely drawn on the excellent work now done in this country in the line of food analysis by government and state and by local boards and associations. Many additions are noted, such as detailed descriptions of special arrangements for polarimetry, distillation and extraction, new processes for detection of colors used as substitutes for natural colors of fruits and eggs; improved methods for detection of formaldehyd and saccharin; rapid methods for examination of vanilla and lemon essences; for determining fat in condensed milk and cereal foods, boric acid in fruit juices, together with analytic data concerning preserved fruits and their preparations. While no information concerning the lines in regard to adulteration or discussion of food standards are given, the U. S. Government standards are included as official interpretation of analytic data.

Outlines of Inorganic Chemistry. By F. A. Gooch and C. P. Walker. Cloth. Pp. 514. Price, $1.75 net. New York: The MacMillan Co. 1906.

The subject is presented through such experimental work as has long been tested in college and in such relation as to facilitate drawing the deductions essential to a proper comprehension. The consecutive experimental development of the principles on which systematic chemistry rests is considered, together with the electrical phenomena and ions and the constitution of the acids, bases and salts from the ionic point of view, and the thermal relations based on the recognition of equivalents, electrical, chemical and thermal. The molecule in its relation to the atom, in the light of the kinetic theory of gases, in the theories of Van t'Hoff and Werner, the phenomena of solutions, the electrolytic theory of dissociation and the modern conceptions of the ions are all discussed. The elements, their compounds and properties are considered in accordance with the periodic system. Graphic symbols are used because their real functions for co-ordinating facts are rarely misinterpreted. The ionic terminology is employed and the functions of ions are pointed out, but the extreme developments of free ions have not been introduced.

Manual of Gynecology. By D. Berry Hart, M.D., F.R.C.P.E., F.R.S.E., Lecturer on Midwifery and Gynecology School of the Royal College, Edinburgh, and A. H. Freeland Barbour, M.A., B.Sc., M.D., F.R.C.P.E. F.R.S.E., Lecturer on Midwifery and Diseases of Women, School of the Royal Colleges, Edinburgh. With 12 Lithographs and 359 Woodcuts. Sixth Edition. Cloth. Pp. 736. Price, $6.00. Chicago: W. T. Keener & Co. 1905.

In this, the sixth edition of this manual of gynecology, the whole text has been carefully revised and brought up to date. The subject matter is well arranged and the illustrations are excellent. The appendix includes a chapter on preparation for and technic of abdominal section in gynecologic cases, and a practical method of taking histories in these cases. There is also a very complete list of works on gynecologic subjects in English, German and French, with authors, which should facilitate reference work.

A Hand-Book of Nursing. Revised Edition. For Hospital and General Use. Published under the Direction of the Connecticut Training-school for Nurses. Cloth. Pp. 319. Price, $1.25. Philadelphia: J. B. Lippincott Co. 1905.

This book is distinguished from some other works on the same subject by providing instruction for hospital nurses in preparation for their work later in private families. The nurse's relation to the patient, to the family and to the physician are clearly set forth. The chapter on family hygiene, while not exactly pertaining to nursing, is of practical value.

Miscellany

THE LANE LECTURES.

INTERESTING ACCOUNT OF THIS SERIES OF LECTURES AT COOPER MEDICAL COLLEGE, SAN FRANCISCO.

The Lane Lectures for 1905 were delivered during the week beginning August 13 by Sir Patrick Manson, the eminent authority on tropical diseases, who took for his subject some of the more important aspects of tropical medicine. Sir Patrick began his first lecture by remarking that thirty years ago there was no tropical medicine to speak of, and cited various important diseases discovered since that time to substantiate this view. He pointed out the importance of helminthology in the study of disease, and suggested that it served as an excellent introduction to the study of the more complicated bacteriology. He spoke of the increasing importance of the protozoa in pathology, and the gradual usurpation of this class of parasites of the premier place hitherto held by bacteria. The great importance of insects in the transmission of certain classes of disease was discussed in a general way, the work of Ross receiving special attention. After these introductory remarks, and a few words as to the likelihood of San Francisco becoming a center for tropical disease, the speaker briefly outlined the ground which he proposed to cover in his course of ten lectures.

The first lecture was mainly taken up with the consideration of certain general principles determining the occurrence of disease in the tropics. The speaker pointed out first that like the larger animals and plants, disease germs were unevenly distributed over the earth. The important factor in determining differences in distribution is the climate, and particularly the temperature. As a result of climatic differences the regular flora and fauna vary in different climates but the bacterial flora and fauna show no such marked variation in distribution as their normal habitat is the body of man, which shows practically no variation in different parts of the world. Though practically all the diseases of temperate climates can flourish in the tropics there are some tropical diseases which can not spread in temperate climates even if they are introduced there. In connection with the introduction of tropical diseases into colder climates the lecturer spoke of the latency of certain tropical diseases, a factor which is often overlooked, and which leads to errors in diagnosis. He cited as examples cases of blackwater fever and sleeping sickness which had developed in England months or even years after the individual had been in the tropics. After referring to one or two diseases, as tinea impricata and pinta, which can not be exported from the tropics because the moisture and temperature conditions are lacking elsewhere, the lecturer explained why certain tropical diseases can be exported to, but can not be spread in, temperate climates. The reason generally has to do with the life history of the parasite causing a given disease during the period in which it is passing, or being carried from one human host to another. Some parasites, as the uncinaria, have undergone development in earth for a certain period of time before they can reinfect man. If this earth is not of the proper temperature the embryos cannot develop and therefore are incapable of infecting man. Other parasites need for their development water at a certain temperature found only in tropical countries. Again an intermediate host, found only in the tropics, may be needed for the full development of the parasite, or the parasite may be unable to escape from the body without the aid of some tropical suctorial insect. In other instances some large

modified in the case of vaccinia, by its passage through the cow. He showed that the life history of this parasite outside of the body is only imperfectly known, though it seems probable that a fly of some sort acts as an intermediate host.

Several lectures were then devoted to the discussion of the diagnosis of malaria, and the several tropical diseases which are commonly confused with it. In the diagnosis of malaria the lecturer emphasized three points; the periodicity of the paroxysms, the blood examination, and the therapeutic test. Mediterranean fever, liver abscess, relapsing fever, tropical febrile splenomegaly, and leprosy were all mentioned as tropical diseases likely to be mistaken for, and treated as malaria. The differential diagnosis of these different conditions was fully discussed, and several points of importance were brought out. In connection with Mediterranean fever Dr. Manson emphasized the lack of value of the serum test under ordinary circumstances. He pointed out that the condition of the culture of *Micrococcus melitensis* was of great importance, as was the personal equation of the observer. In the remarks on liver abscess stress was laid on the insidious character of the symptoms. In discussing this point the lecturer brought forward two aphorisms which he had formulated as a result of his experience in China, where he observed a great deal of liver abscess and thoracic aneurism. These were, to suspect thoracic aneurism in all obscure non-febrile thoracic complaints, and to suspect liver abscess in all obscure febrile abdominal conditions. In diagnosis of liver abscess the necessity of repeated exploratory needle punctures was emphasized, and it was advised that such punctures be always done under an anesthetic, and that when the abscess was found the needle should be left *in situ*, and operation proceeded with immediately.

In the ninth lecture Sir Patrick Manson briefly considered the treatment of the diseases he had previously discussed, and also that of dysentery and sprue. As a prophylactic measure he advised cautioning all patients leaving the tropics that they should continue precautionary measures against tropical diseases for at least six months after their departure. In considering dysentery physicians were advised to regard it as, in a sense, a surgical condition, and to look on the intestinal canal as a large drainage tube. The principles of treatment included the removal of the discharges from the ulcers, and the use of agents having a direct effect on the specific causes of the disease. The treatment advocated consisted in absolute rest, the reduction of food to a minimum for a time, mild catharsis, preferably with small doses of castor oil, and the internal administration of ipecac. The latter drug Dr. Manson regards as almost specific, and thinks it has fallen into disrepute, especially in the United States, on account of its improper use. In the treatment of sprue, which the lecturer regarded as a very dangerous disease if improperly treated, absolute rest, a restricted diet of milk, and in some cases strawberries was recommended. In some cases scraped meat was allowed. The rest and the restriction of the diet until at least six weeks after the stools became normal was insisted on.

In the final lecture some of the unsolved problems in tropical medicine were considered. In connection with yellow fever Dr. Manson suggested two lines of research. He stated that the relative immunity of the old inhabitants in yellow fever districts was very often not due to previous attack, and that the reason for this immunity was yet to be solved. He suggested that there might be two strains of yellow fever virus, an attenuated and a virulent one, just as in the case of smallpox and vaccinia. One line of work suggested was the determination of the clinical picture presented by the inhabitants of a yellow fever district while going through this immunizing stage. Another problem suggested was the study of the effects on the malarial parasite and other insect-carried germs of passing them through different species of mosquitoes. In connection with yellow fever, the danger that this disease might be conveyed to the tropical portions of Asia by the opening of the Panama Canal was discussed, and it was pointed out that the United States would have to face the problem of the prevention of this spread. Dr. Manson suggested that this could be done without serious inconvenience to human beings, as the war must be waged on the stegomyia mosquito. Other problems to be studied related to the peculiar distribution of such diseases as malaria and filariasis. With equally infected territory so far as mosquitoes were concerned, and with equal chances of contamination of these, similar districts were often very differently infected.

The final lecture was closed by a plea for the teaching of tropical medicine as a special study for those whose work was likely to take them to the tropics. San Francisco was considered by the lecturer to be the most favorably situated city in the United States for the establishment of a school of tropical medicine, and this was suggested. Education of school children in tropical districts and of government employes was also insisted on, and especial stress was laid on the necessity for education regarding the rôle which insects play in the transmission of tropical diseases.

Weak Heart Sounds.—Hoffman says (American Year Book of Medicine): If the aortic second sound becomes very weak, and the second pulmonary sound likewise, in infectious diseases, it indicates great weakness of the heart, and is, therefore, a bad sign. Marked weakness of the second pulmonary sound in mitral valvular disease indicates imperfect compensation. Marked weakness of the sounds at the base, as compared with those at the apex, indicates an alcoholic heart. Marked weakness of the sounds at the apex, as compared with those at the base, show a fatty heart.—*Denver Med. Times.*

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Pneumonia.

Ewart, in *London Lancet*, recommends for the shock of invasion of pneumonia, recumbency, warmth and a small dose of ether or brandy with hot water. In addition a small dose of ammonium bromid with the aromatic spirits of ammonia and from 5 to 10 drops (.30-.65) of a solution of morphin (1 per cent.) in aqua chloroformi to prepare the patient for sleep is advisable. An initial dose of calomel is also recommended, followed by a senna draught.

The author states, in relation to cardiac treatment, that arrangements must be made for the administration of oxygen to be commenced early and given continuously, as a valuable aid to the heart against fatigue, and not postpone its administration until the desperate state is reached. It has the advantage over the continuous administration of alcohol in being harmless and in not affecting the alimentary tract. The glass funnel should be avoided in the administration of oxygen as very unsuitable. The best means is to place the end of the tube between the lips or immediately in front of the mouth. He recommends leeches applied early to the seat of pain, and makes this a part of the treatment regularly. He also recommends the early application before the deposition of fibrin has taken place and not their application during the stage of exhaustion.

Sweating may be promoted by the hot-air bath to the lower extremities or a hot mustard footbath, but the patient must not be fatigued by these measures.

As to the medicinal treatment, the chief aims are to promote diaphoresis, diuresis, fibrinosis and absorption. To meet these indications the author recommends a combination of ammonium citrate and sweet spirits of nitre together with warm beverages. To improve the cardiac condition he recommends gin as superior to alcohol in some respects, as it is a better diuretic. Oxygen, as has been stated, is recommended early in the disease, and sound sleep as peerless in keeping up the heart's strength.

In order to check the tendency to coagulation, citric acid is recommended as a precipitant of calcium, which aids clotting. The carbonates and iodids act similarly, but the carbonates tropical animal carries the cause of a given disease in its body and keeps it alive until the necessary human victim comes along. In certain toxic diseases certain media found only in the tropics, and a tropical temperature may be needed before the poisons will develop.

As his first example of a disease whose parasite needed intermediary development at a high temperature Sir Patrick Manson cited ankylostomiasis (uncinariasis). In a general way he traced out the factors concerned in the spread of the disease and in its prevention. He supported Loos' view that infection occurs through the skin, cautioned as to the danger of the disease spreading, and emphasized the necessity for examination of the stools in all obscure and resistant cases of anemia. He emphasized the danger from Porto Ricans, already pointed out by Gunn, and called attention to the Chinese as sources of infection.

He next considered diseases in which the embryo escapes into water and undergoes development in the interior of water animals before becoming infective for the human being. As an example of this form of infection he cited dracontiasis or guinea-worm disease. He gave an interesting description of the life history of the guinea worm (*Dracunculus medinensis*) showing that in all probability it penetrates through the skin, especially in those portions most likely to come in contact with water, giving the history of its development in the subcutaneous tissues, its approach to the surface when it is full of embryos, and its method of expelling these when the infected part is brought in contact with water. He described the life history of the embryos in water, their development in certain varieties of cyclops, and their probable fate so far as this could be surmised from knowledge and analogy. He advised American physicians to be on the lookout for this disease in those returning from the tropics with small leg ulcers with central openings, and cautioned against meddlesome attempts at removing the worm before all its embryos had escaped, which treatment he aptly compared to meddlesome midwifery. As a second example of this type of disease he cited the parasitic hemoptysis of Formosa and Japan, due to infection with the lung fluke (*Paragonimus westermanii*). He pointed out that this parasite has been described by Ward and others in the United States in cats, dogs, and pigs, and hazarded the opinion that human infections would, in the course of time, be discovered here. He described the life history of the organism as far as known, and pointed out the necessity for wider knowledge, as, once in the body, we are powerless to remove the flukes, except in rare cases of brain infection with localizing symptoms. The third form of parasite requiring development in water which the lecturer described was the *Schistosomum hematobium*, the cause of bilharziasis. He described the life history of this trematode in the body, showed that the localization of the ova in the bladder and rectum resulted from an attempt to reach the outer world and their natural habitat water, and described the development of the embryo from the egg as far as this is known. Attention was called to the fact that the disease exists in the West Indies, has been imported into the United States, and may become distributed in this country. The lecturer called attention to the new Asiatic representative of this family, the *Schistosomum cattoi*, and in discussing the peculiarities of the eggs of the vesical and rectal infections, suggested that there were probably several varieties of Schistosomum. He dwelt on the susceptibility of cats to this infection as a factor which made the possibility of infection of this country more likely, and suggested the examination of the urine in all doubtful cases of hematuria, and of the feces in all obscure rectal irritations for the characteristic ova.

Dr. Manson then took up the discussion of those tropical diseases which are limited in range on account of requiring certain suctorial insects as intermediate hosts. He considered first the various forms of filariasis, pointing out that the canine form occurs in this country, and that other forms may occur. He described the habitat of the adult worm in the lymph vessels, the passage of the embryos into the blood, their removal by certain varieties of mosquito, and their subsequent development in the stomach and muscles of the host. He then described how they passed into the neighborhood of the proboscis, and escaped into the new human host at the time that the insect bit. He discussed the relation of this form of infection to endemic elephantiasis, lymph varices, and chyluria, and remarked on the mystery of the periodical disappearance of the embryos from the blood, which has never been satisfactorily explained. Malaria was next considered, and a very interesting comparison was drawn between the early stages of the filarial embryo and the malarial parasite; in both diseases the parasite reaches a non-motile or restrictedly motile stage in the blood, in both instances it is protected from injury by a covering (in the filaria its sheath and in the plasmodium the red corpuscle), and both parasites undergo further development only in the tissues of the mosquito. The description of the malarial parasite was clear and interesting, and the relation of this disease to the mosquito was proved, as the lecturer said, "to the hilt." Dr. Manson expressed the belief that mosquito transmission was probably the only method of transmission of this disease. The prophylaxis of the disease, and the history of its introduction into new territories was discussed.

The subject of trypanosomiasis, and the relation of trypanosomes to sleeping sickness was next discussed. A clear clinical description of infection with the *Trypanosoma gambiense* followed the lecturer's remarks on the structure of trypanosomes in general. This form of trypanosomiasis is characterized by a low form of fever, muscular weakness, an erythematous skin eruption of a smudgy ill-defined character, patchy edema, tachycardia, enlargement of the spleen and lymph glands, and an increase in the large mononuclears of the blood. In connection with trypanosomic infections Dr. Manson discussed at length the relation of these parasites to sleeping sickness. He described the spread of this peculiar and fatal disease from a small area on the West coast of Africa to the East Coast, and commented on the ravages it had made in certain sections, particularly in Uganda. *He graphically* described the clinical picture, the low fever, the *headache*, lassitude followed by lethargy, the pessimistic and morose mental condition, the enlargement of the *spleen and* lymph glands, and the pruritus. He compared *the disease* with general paresis both in its clinical and pathologic manifestations. In his historical sketch of the disease he pointed out that it had been imported into the United States many times in the *days of slavery, but had never* spread. In discussing the relation to trypanosomes he took a conservative stand, and suggested that though there was in all probability an etiologic relationship further research was necessary.

The lecturer then described a closely allied form of infection, kala-azar, or as he preferred to call it, tropical febrile splenomegaly. This also is a chronic febrile disease characterized by fever of a variable type, anemia, prostration, and emaciation; the liver and spleen are always enlarged, sometimes very markedly. The disease seems to be almost invariably fatal. So far this disease has not been described in the western hemisphere, but is limited *to Africa*, India, and China. In Assam it has in recent years almost decimated the population in some districts. The recent discovery of the parasite by Leishman was interestingly described, and its oval form, macronucleus and micronucleus, and grouping into masses were pictured. Its close relation *to* the trypanosomes, and the demonstration of *this by* the cultural work of Rogers was mentioned. Attention was also called to the valuable work of Wright of *Boston in* connection with oriental sore, in which it was *shown that* this condition is associated with what is morphologically an identical parasite. Dr. Manson suggested that *in tropical* febrile splenomegaly the parasites leave the body by means of surface sores or intestinal ulcerations. He pointed *out* the difficulty of explaining the fact that tropical febrile splenomegaly, a very fatal disease, and oriental sore, a non-fatal disease, are associated with what appears to be *the same parasite*. He cited a belief that oriental sore occurred only in countries where camels are found, and suggested that it might be due to the action of the parasite modified by passage through the camel, while tropical febrile splenomegaly might be due to the same parasite unmodified. This supposition would assume an analogy to smallpox and vaccinia which are due to the same germ, modified in the case of vaccinia, by its passage through the cow. He showed that the life history of this parasite outside of the body is only imperfectly known, though it seems probable that a fly of some sort acts as an intermediate host.

Several lectures were then devoted to the discussion of the diagnosis of malaria, and the several tropical diseases which are commonly confused with it. In the diagnosis of malaria the lecturer emphasized three points; the periodicity of the paroxysms, the blood examination, and the therapeutic test. Mediterranean fever, liver abscess, relapsing fever, tropical febrile splenomegaly, and leprosy were all mentioned as tropical diseases likely to be mistaken for, and treated as malaria. The differential diagnosis of these different conditions was fully discussed, and several points of importance were brought out. In connection with Mediterranean fever Dr. Manson emphasized the lack of value of the serum test under ordinary circumstances. He pointed out that the condition of the culture of *Micrococcus melitensis* was of great importance, as was the personal equation of the observer. In the remarks on liver abscess stress was laid on the insidious character of the symptoms. In discussing this point the lecturer brought forward two aphorisms which he had formulated as a result of his experience in China, where he observed a great deal of liver abscess and thoracic aneurism. These were, to suspect thoracic aneurism in all obscure non-febrile thoracic complaints, and to suspect liver abscess in all obscure febrile abdominal conditions. In diagnosis of liver abscess the necessity of repeated exploratory needle punctures was emphasized, and it was advised that such punctures be always done under an anesthetic, and that when the abscess was found the needle should be left *in situ*, and operation proceeded with immediately.

In the ninth lecture Sir Patrick Manson briefly considered the treatment of the diseases he had previously discussed, and also that of dysentery and sprue. As a prophylactic measure he advised cautioning all patients leaving the tropics that they should continue precautionary measures against tropical diseases for at least six months after their departure. In considering dysentery physicians were advised to regard it as, in a sense, a surgical condition, and to look on the intestinal canal as a large drainage tube. The principles of treatment included the removal of the discharges from the ulcers, and the use of agents having a direct effect on the specific causes of the disease. The treatment advocated consisted in absolute rest, the reduction of food to a minimum for a time, mild catharsis, preferably with small doses of castor oil, and the internal administration of ipecac. The latter drug Dr. Manson regards as almost specific, and thinks it has fallen into disrepute, especially in the United States, on account of its improper use. In the treatment of sprue, which the lecturer regarded as a very dangerous disease if improperly treated, absolute rest, a restricted diet of milk, and in some cases strawberries was recommended. The final lecture was closed by a plea for the teaching of tropical medicine as a special study for those whose work was likely to take them to the tropics. San Francisco was considered by the lecturer to be the most favorably situated city in the United States for the establishment of a school of tropical medicine, and this was suggested. Education of school children in tropical districts and of government employes was also insisted on, and especial stress was laid on the necessity for education regarding the rôle which insects play in the transmission of tropical diseases.

Weak Heart Sounds.—Hoffman says (American Year Book of Medicine): If the aortic second sound becomes very weak, and the second pulmonary sound likewise, in infectious diseases, it indicates great weakness of the heart, and is, therefore, a bad sign. Marked weakness of the second pulmonary sound in mitral valvular disease indicates imperfect compensation. Marked weakness of the sounds at the base, as compared with those at the apex, indicates an alcoholic heart. Marked weakness of the sounds at the apex, as compared with those at the base, show a fatty heart.—*Denver Med. Times.*

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Pneumonia.

Ewart, in *London Lancet*, recommends for the shock of invasion of pneumonia, recumbency, warmth and a small dose of ether or brandy with hot water. In addition a small dose of ammonium bromid with the aromatic spirits of ammonia and from 5 to 10 drops (.30-.65) of a solution of morphin (1 per cent.) in aqua chloroformi to prepare the patient for sleep is advisable. An initial dose of calomel is also recommended, followed by a senna draught.

The author states, in relation to cardiac treatment, that arrangements must be made for the administration of oxygen to be commenced early and given continuously, as a valuable aid to the heart against fatigue, and not postpone its administration until the desperate state is reached. It has the advantage over the continuous administration of alcohol in being harmless and in not affecting the alimentary tract. The glass funnel should be avoided in the administration of oxygen as very unsuitable. The best means is to place the end of the tube between the lips or immediately in front of the mouth. He recommends leeches applied early to the seat of pain, and makes this a part of the treatment regularly. He also recommends the early application before the deposition of fibrin has taken place and not their application during the stage of exhaustion.

Sweating may be promoted by the hot-air bath to the lower extremities or a hot mustard footbath, but the patient must not be fatigued by these measures.

As to the medicinal treatment, the chief aims are to promote diaphoresis, diuresis, fibrinosis and absorption. To meet these indications the author recommends a combination of ammonium citrate and sweet spirits of nitre together with warm beverages. To improve the cardiac condition he recommends gin as superior to alcohol in some respects, as it is a better diuretic. Oxygen, as has been stated, is recommended early in the disease, and sound sleep as peerless in keeping up the heart's strength.

In order to check the tendency to coagulation, citric acid is recommended as a precipitant of calcium, which aids clotting. The carbonates and iodids act similarly, but the carbonates should be avoided in pneumonia because of the gastric inflation produced, which is indirectly very detrimental to the heart's action. The iodids, however, are highly recommended in the treatment of this disease, as diminishing the tendency to coagulation and, on the other hand, increasing absorption of the fibrinous deposits. He recommends it in doses of 60 grains (4.00) a day, or more, if necessary. A combination similar to the following is recommended:

℞.	Potass. iodidi	gr. v		30
	Liq. ammon. cit	ʒii	8	
	Spts. etheris nitrosi	ʒss	2	
	Spts. ammon. arom	m. xx	1	30
	Aquæ chloroformi q. s. ad	℥ss	15	

M. Sig.: One tablespoonful diluted, to be taken every hour for six doses, then every three hours.

Colchicum in Gout.

The following combinations by Beasley containing colchicum are recommended in the treatment of gout:

℞.	Ext. colchici			
	Ext. rhei			
	Ext. aloes soc., āā	gr. xxx	2	
	Ext. belladonnæ	gr. v		30

M. Ft. pil. No. xxx. Sig.: One pill twice a day. Or:

℞.	Pulv. colchici sem.	gr. lxxii	4	75
	Sodii salicylatis			
	Magnesiæ (calcined), āā	ʒii	8	

M. Ft. cachet No. xxiv. Sig.: One every four hours. Or:

℞.	Colchicinæ salicylatis	gr. ss		03
	Methyl salicylatis	ʒiiss	10	
	Ol. menth. pip	m. xxx	2	

M. Ft. cap. No. xxx. Sig.: One capsule three times a day. Or:

℞.	Tinct. colchici	ʒiss	6
	Tinct. cimicif.	ʒi	4
	Tinct. bellad.	ʒss	2
	Sodii bicarb.	ʒiii	12
	Inf. gent. co. q. s. ad	℥vi	180

M. Sig.: Shake the bottle and take one tablespoonful in water every four hours. Or:

℞.	Tinct. colchici	ʒiii	12
	Tinct. bellad.	ʒi	4
	Lithii citratis	ʒii	8
	Elix. simplicis q. s. ad	℥iii	90

M. Sig.: One teaspoonful after meals, in water.

In cases of gouty rheumatism the following combinations are recomemnded:

℞.	Vini colchici	ʒi	4
	Magnes. sulph.		
	Potass. bicarb., āā	ʒiv	15
	Sodii salicyl.	ʒiss	6
	Aquæ chloroformi q. s. ad	℥iv	120

M. Sig.: One tablespoonful with a teaspoonful of lemon juice, while effervescing, three times a day. Or:

℞.	Colchicinæ salicyl	gr. ss		03
	Acidi salicylici	ʒiss	6	

M. Ft. pil. No. xxx. Sig.: One pill every four hours during the day.

Prophylaxis of the Diarrheal Diseases of Childhood.

Dr. Seneca Egbert, in *Med. Bull.*, states, for an efficient prophylaxis of the diarrheas of children, that both the predisposing and exciting causes must be considered. Among the former heat is a most powerful factor. Everything possible should be done to keep the babies cool; the clothing should be reduced to a minimum consistent with safety, keeping in mind the possibility of sudden changes in temperature and the dangers which may arise therefrom in the way of deranging the intestinal functions.

Living and sleeping rooms should be kept as cool and as well ventilated as possible. The fear of "night air" should be removed from the minds of the patients. The country or seashore is much preferable during the heated term to the city. If necessary to keep the body temperature down, the bath should be resorted to frequently—twice or three times a day, if necessary—and the baby should be given plenty of clean, sterile and cool water to drink. Milk is the most important article of diet during the first year or so of the infant's life and up to the first quinquenium. It should be pure and not over forty-eight hours old, and should be sterilized or pasteurized soon after taken from the cow. Cleanliness to the extreme should be observed with everything about the child. Napkins and soiled clothing should be promptly boiled or sterilized, as most of the diarrheal discharges are probably infectious.

The importance of excluding house flies and other insects from access to the infants not only to prevent any disturbance of their sleep, but to prevent the carrying of infection from fecal discharges and transmitting germs of the most harmful character.

Laryngeal Manifestations of Influenza.

E. J. Moure, in the Pract. Med. Series of "Year Books," states that the laryngeal manifestations of influenza are found under four forms: 1, The catarrhal form; 2, the infiltrated edematous form; 3, the ulcerative form, and 4, the myopathic form. As local treatment the author recommends an inhalation from a pint of hot water containing a teaspoonful of the following:

℞.	Menthol	gr. x		65
	Balsami peruviani	ʒss	2	
	Thymol	gr. i		06
	Tinct. eucalypti q. s. ad	℥ii	60	

M. Sig.: One teaspoonful floated on a pint of hot water as an inhalation.

Hot fomentations around the neck are very useful in the painful congestive forms.

Scarifications may be necessary in the markedly edematous forms, but usually the following combination as a spray will give relief:

℞.	Cocainæ muriatis	gr. ii-iiiss		12-.20
	Sol. adrenalin (1-1,000)	m. xl	2	65
	Antipyrin	ʒi	4	
	Glycerini			
	Aq. menth. pip., āā	ʒvi	24	
	Aquæ q. s. ad	℥vi	180	

M. Sig.: To be used as a spray three or four times a day.

Later in the course of the trouble, when the infiltration has disappeared, good results are obtained, according to the author, from the application of a silver nitrate solution or zinc chlorid 1/100 or 1/50, or it may be as strong as 1/30.

In cases of edema of the glottis in such conditions, or from the various other causes, J. C. Gittings states that intubation rarely affords relief unless the obstruction is infraglottic. Tracheotomy is demanded in extreme cases. The continuous inhalation of medicated steam is always to be employed; scarification and external depletion by leeches is recommended. Cold and heat should be used externally and internally—cold as a prophylactic and heat as a stimulant and absorbent. Stimulating and supportive treatment is necessary in such cases.

Medicolegal

Compulsory Physical Examination.

The Supreme Court of Montana says, in May vs. Northern Pacific Railway Co., that on the question of whether, in an *action for personal injuries, a court may compel the plaintiff* to submit to a physical examination by physicians and surgeons appointed by the court, the authorities are in hopeless conflict, and any attempt to reconcile them would be barren of results. The first reported case in which the power of the court to compel such examination is asserted is Walsh vs. Sayre, 52 How. Prac. 334, decided by the New York Superior Court in 1868. This was an action for damages for malpractice, and on the analogy to cases of mayhem, divorce on the ground of impotency, and cases of controversies between a widow claiming to be pregnant by the decedent, and other heirs of the estate, wherein such examinations had been ordered, it was held that a court of law could compel the plaintiff to submit to a physical examination. A leading case on the subject is Schroeder vs. Railway Co., 47 Iowa, 375, decided in 1877. Mention is not made of the New York case cited above. The opinion states that there were no precedents at the time of its rendition. The power of the trial court to compel the *plaintiff* to submit to such an examination is asserted.

After continuing the review showing the decisions of courts on the first presentation of this question to them, the Supreme Court of Montana says that the case of Walsh vs. Sayre was followed in Shaw vs. Van Rensselaer, 60 How. Prac., 143; but in 1891 the question came before the Court of Appeals of New York in McQuigan vs. Railway Co., 129 N. Y., 50, and Walsh vs. Sayre and Shaw vs. Van Rensselaer were overruled. The McQuigan case was followed in Cole vs. Fall Brook Coal Co., 159 N. Y., 59, decided in 1899. The Legislature of New York, however, circumvented the effect of these last decisions by enacting a statute directly conferring upon trial courts the power to make and enforce such an order. Then follows a further review of decisions, and the statement that if the last announcements of these several courts may be taken to indicate the law in their respective states, a review of the decisions discloses that the power of trial courts to compel such examinations is asserted in Alabama, Arkansas, Georgia, Iowa, Indiana, Kansas, Kentucky, Michigan, Minnesota, Missouri, North Dakota, Washington and Wisconsin, and denied in the federal courts, and in Illinois, Massachusetts and Texas, and was denied in New York until specifically granted by direct legislative enactment.

The bare assertion that trial courts possess this power, in the absence of any legislation, and without common law precedents, has led to the greatest possible confusion among the decisions of the very courts asserting it. (1) What is the source of the power? (2) To what extent may it be carried? (3) May the defendant demand the order as a matter of right? And (4) how will the court enforce obedience to its order?

1. Singularly enough, the first of these questions appears to have received little or no consideration. In some of the opinions it is said that the power is one inherent in the trial courts. In Graves vs. Battle Creek, 95 Mich. 266, decided in 1893, it is said, "It is true that the rule is one of modern growth." Most of the courts content themselves with the bare assertion of the power, without any discussion of its origin.

2. If the plaintiff may be compelled to submit to a physical examination, is the authority to order it an absolute or only a qualified one? May the plaintiff be compelled to submit to the administration to him of anesthetics or drugs by which he loses consciousness altogether, or, if the injury is an internal one, may he be compelled to submit to the use of such surgical instruments as the physicians appointed to make the examination may see fit to use? May he be compelled to exhibit the injury to the jury in open court, and, if the plaintiff be a woman, is there any protection whatever against violence to her feelings? By some of these courts it has been held that anesthetics and drugs should not be used (Schroeder vs. Railway Co., Strudgeon vs. Sand Beach, 107 Mich., 496), and that the plaintiff should not be compelled to submit to the use of surgical instruments (O'Brien vs. La Crosse, 99 Wis., 421); but in Railway Co. vs. Palmore, 68 Kan., 545, it was held that the plaintiff could be compelled to submit to the examination, and to an injection of a drug into his injured eye to dilate the pupil; and in Hall vs. Manson, 99 Iowa, 698, it was held that the plaintiff, a woman, could be compelled to remove her shoe and stocking, that an examination might be had and measurements taken of her injured ankle in the presence of the jury. In Railway Co. vs. Hill, 8 South., 90, the Supreme Court of Alabama said: "When it becomes a question of possible violence to the refined and delicate feelings of the plaintiff on the one hand, and possible injustice on the other, the law can not hesitate. Justice must be done." This is quoted with approval in Lane vs. Railway Co., 21 Wash., 119. However, in Graves vs. Battle Creek, it is said: "The decisions are not uniform on this question, but the great weight of authority is in favor of the exercise of such power by the court under proper restrictions; the rule recognizing, however, that a wide discretion is vested in the trial court, which justifies a refusal to require the examination . . . where the sense of delicacy of the plaintiff may be offended by the exhibition." To the same effect is the decision in Ottawa vs. Gilliland, 63 Kan., 165.

3. In Sibley vs. Smith, 46 Ark., 275, and in Railroad Co. vs. Thul, 29 Kan., 466, it is held that the defendant may demand the order as a matter of right, but that in granting it the court may exercise its discretion. This court (the Supreme Court of Montana) is unable to understand this contradiction of terms, and observes that in most of the cases it is held that the application is one addressed to the sound discretion of the trial court, subject to review for manifest abuse only.

4. In the Schroeder Case and in Sibley vs. Smith it is said that refusal of the plaintiff to comply with the order would constitute contempt of court, and subject the plaintiff to the punishment of a recusant witness; while in Turnpike Co. vs. Baily, 37 Ohio St., 104; Lane vs. Railway Co., Wanek vs. Winona, 78 Minn., 98; Brown vs. Railroad Co., 12 N. D., 61, and in the dissenting opinion in Railroad Co. vs. Botsford, 141 U. S., 250, it is said that it is not a question of contempt; that the court can not compel the plaintiff to comply with the order which it has made, but, if he refuses, the court may dismiss his action or refuse to permit him to testify.

From the assertion of the power arising from the apparent necessities of extraordinary cases, as disclosed by the decision in the Schroeder Case, we observe the almost limitless extent to which the power has been carried; and, not content with applying the rule to civil actions for personal injuries, it has been extended to apply to the prosecuting witness in a criminal case (King vs. State, 100 Ala., 85), and, for the same reasons advanced for the exercise of the power in civil action by the courts asserting its existence, the doctrine has been applied to a criminal case, and the defendant compelled to bare to the view of the jury part of the unexposed portions of his body on which were certain tattoo marks, in order to enable the state to complete the case against him, with the result that the defendant was convicted of a capital offense. State vs. Ah Chuey, 14 Nev., 79.

The only instances in which such power was invoked at common law were in actions for divorce upon the ground of impotency, appeals of mayhem, cases of atrocious battery, cases of conviction of a woman of a capital crime who is alleged to be pregnant, and controversies between heirs and a widow claiming to be pregnant by the deceased. No one of these rules has ever obtained in this country, unless it has been in cases of divorce on the ground of impotency. The power was exercised by the English ecclesiastical courts, and was a graft from the civil law.

The reasons advanced by the courts for the exercise of this power, in the absence of any direct authority, the Supreme Court of Montana goes on to say, do not commend themselves to it. It says that it is said by some that the power is analogous to the proceeding for discovery; but discovery was not compelled by the law courts at common law. By other courts it is said that the assertion of this power is necessary to prevent the plaintiff from maligning and bolstering up a fictitious case "by the very unreliable speculations of so-called medical experts." Wanek vs. Winona, above cited. It is a curious process of reasoning which enables a court to characterize the solemn testimony of medical men as unreliable speculations when the witnesses are called by the plaintiff, but if these same physicians be called by the court, on application of the defendant, they immediately become the instrumentalities through which, not approximate, but exact, justice is to be done. Others, including the dissenting opinion in the Botsford Case, say it is strange that the plaintiff may, if he chooses, exhibit his injury to the jury, or may testify concerning it, or may have other witnesses do so, but he can not be compelled to make such exhibition. This court is of the opinion that even if the plaintiff might, as a matter of right, exhibit his injuries to the jury, it would not add to the argument in behalf of that view of the case. In this state (Montana), however, he does not possess that right. He may offer to do so, but it is within the discretion of the court to permit or refuse the offer, subject, of course, to review for a manifest abuse of that discretion.

The right to the inviolability of one's person is merely a privilege which the plaintiff may waive, as a defendant may the constitutional guaranty that in a criminal case he can not be compelled to be a witness against himself. As a defendant may give evidence against himself, but can not be compelled to do so unless he waives the privilege, so the plaintiff may exhibit portions of the clothed parts of his body to the jury, if the court permits, but can not be compelled to do so. The constitutional guaranty is not more solemn and binding in one instance than in the other. And, for the much stronger reason, the plaintiff can not be compelled to make such exhibition of himself to third parties, strangers to the case, in order that they may procure material for testimony.

Current Medical Literature

AMERICAN.

American Medicine, Philadelphia.

August 19.

1 *Matas Operation for the Cure of Aneurism. J. H. Gibbon, Philadelphia.
2 *Treatment of Chancre and Chancroid. D. E. Wheeler, Buffalo.
3 Elimination of Endogenous Uric Acid in a Case of Chronic Gout. A. T. Laird, Albany, N. Y.
4 *Antituberculosis Work in the United States Army, Navy and Marine-Hospital Services. G. H. Kress, Los Angeles.
5 *Treatment of Infected Otitis Media. J. G. Huizinga, Grand Rapids, Mich.
6 *Enterotoxismus as a Substitute for Autointoxication. H. A. Houghton, New York.

1. **Matas Operation for Cure of Aneurism.**—Gibbon describes the operation and reports one case, that of a negro aged 31, who suffered from a large popliteal aneurism. The sac was laid open and the arterial openings sutured. The sac was then obliterated by repeated rows of plicating sutures. The wound was closed without drainage. Suppuration took place, but the patient made a complete recovery after superficial drainage was established. Some months after the operation there was no evidence of a recurrence.

2. **Treatment of Chancre and Chancroid.**—Wheeler classifies venereal ulcer into: 1. Simple uncomplicated ulcer, treatment consisting of frequent irrigation and wet dressings. 2. Ulcer complicated by phimosis. If attempts at reducing the phimosis fail, lateral incisions and secondary circumcision should be done; primary circumcision is contraindicated. 3. Ulcer complicated by paraphimosis. If seen early, immediate reduction is imperative; if not seen until sloughing has relieved the strangulation, expectant treatment should be instituted. 4. Phagadenic ulcer. Irrigation should be done every two hours, day and night, and iodoform used. Escharotics are positively contraindicated.

4. **Antituberculosis Work in U. S. Army, Navy and Marine-Hospital Service.**—Kress discusses the antituberculosis work carried on by the medical branches of the three public services. According to the 1900 census the mortality rate from tuberculosis for the registration area of the United States was 187.3 per 10,000 population. In the army, with a total strength of 67,643 in 1904, the mortality rate was 37 per 100,000 whites; 314 per 100,000 negroes; 84 per 100,000 Filipinos; for soldiers of the three races together it was 53 per 100,000—for all races being hardly more than one-fourth as great as in civil life. In the navy, with a total strength of 37,248, there was an increase in 1904 of 104 cases over the figures of 1903. The Marine-Hospital Service cared for 933 tuberculous seamen in hospitals and treated 306 in dispensaries.

5. **Treatment of Chronic Suppurative Otitis Media.**—Huizinga says that this condition can not be cured unless the entire auditory tract can be made surgically clean by forcing the antiseptic fluids through from end to end of the entire tract. It is necessary to have a large opening in the drum and a thoroughly dilated condition of the Eustachian tube, both for the purpose of drainage and of efficient cleansing. It is important to have a continuous current of antiseptic vapor passed through a Eustachian catheter into the Eustachian tube, both for cleansing and dilating purposes. This is best accomplished by connecting a vaporizer containing iodin, menthol and creosote in oil, with a large air tank, having the air compressed up to thirty pounds. The valves are opened and a continuous current of antiseptic air is forced through the catheter and into the Eustachian tube until the pressure goes down to twenty pounds; this requires several minutes. By this method thorough and complete dilation and the cleansing and disinfection from the use of the antiseptic solution are accomplished and the danger of driving infected material that may be present in the Eustachian tube into the deeper parts of the middle ear is avoided. It is necessary to treat the parts sufficiently often to maintain as nearly as possible a condition of antisepsis. No treatment can be considered thorough that does not recognize the relation existing between pathologic conditions in the nose and nasopharynx and the ear.

6. **Enterotoxismus.**—Because the word autointoxication as now used has many different meanings leading to considerable confusion and inaccuracy, Houghton suggests that the autointoxication of enteric origin be designated as enterotoxismus, and gives the following definition: A morbid condition characterized by the absorption of substances from the gastrointestinal tract which are toxic by virtue of their quantity or quality and which are produced therein by the disintegration of foodstuffs through the perverted and prolonged action of enzymes or the activity of entophytes. Classifications are given.

12 Henry G. Davis, M.D. A Review of Some of His Work. J. J. Nutt, New York.
13 *Method for the Sterilization of Sea-Tangle Tents. O. L. Mulot, Brooklyn, N. Y.

7. **Operations for Procidentia Uteri.**—Polk proposes two methods of dealing with this condition. The first is applicable to partial prolapse when retention of the uterus is desired, and has as its purpose the reduction in size and weight of the uterus, and its removal from the posterior and lower parts of the pelvic cavity to the more advantageous position in the anterior and upper parts of this region. This is accomplished by high amputation of the cervix, followed by Alexander's operation and perineal repair. The second procedure is applicable to complete prolapse, and consists in removal of the uterus, and attachment of the vaginal stump to the anterior abdominal wall. The details of this operation are described and illustrated. The author has performed it in 10 cases with excellent results. Perineal repair is essential in this instance also, but the method chosen must not shorten the vagina too much, or there will not be slack enough left to permit the stump to reach the abdominal wall when the laparotomy is done. Vaginal hysterectomy is considered too radical for partial prolapse, and not sufficiently so for complete, and the plan of reefing the uterosacral ligaments is also deprecated.

8. **Blood in Relation to Therapeutics.**—Castelli expresses the view that the "future of medicine belongs to hematology," and that hypodermic and intravenous medication must finally replace internal treatment. The blood and lymph, he states, are the bearers and transmitters of any infectious element, and the localization of the infectious element in a special organ or region of the body, is a simple process of metastasis. The microbes, or toxins, are transported by the blood vessels into such regions of the body as offer conditions most suitable for the accomplishment of their reactive processes, just as in a similar manner cancer cells are transported to those parts of the body wherein may be reproduced the malignant growths from which they themselves originated. If the therapeutic agent should follow the same route as that followed by the infective element, its action, general and local, would take effect at such points as presented a necessity for its action.

9. **Practical Points in Pediatrics.**—In dealing with children it is essential, says Kilmer, to gain their respect, confidence and obedience, and to do this tact is required. Children should not be deceived by being told that something is not going to hurt them when it is, for in this way their confidence is irremediably lost. In examining an infant or young child it should always be undressed, and if asleep, it should be studied a while before being roused. A child's chest can not be aus-

culated without the use of a stethoscope, because the average adult ear would cover almost an entire lung of an infant. Sputum is obtained from babies by introducing a catheter, 21 F., into the esophagus, as the act of gagging forces the sputum which is in the esophagus into or on the catheter. The landmarks on an infant's chest are quite different from those of an adult's, and it is impossible to locate the apex beat without the use of the stethoscope. The throat and ears should always be examined when called to a sick baby. Adenoids should never be operated on without an anesthetic, for the nervous shock more than counterbalances the risk of the anesthetic. A simple and practical system of milk modification that can easily be remembered is described, and a blank report is reproduced on which the mother is supposed to record the infant's progress.

10. **Deaf-Mutism and Ptomain Poisoning.**—Bryant describes two cases in which difficulty in walking, deafness, and disorders of speech were apparently produced by food poisoning.

13. **Sterilization of Sea Tangle Tents.**—Mulot advises soaking sea tangle tents for seventy-two hours in tincture of iodin and then immersing them in 95 per cent. alcohol, to remove the surplus iodin. Another method is to boil the tents and then dry them in sterile tubes for a few days in an oven or hot-air chamber, which will cause them to shrink to their original size. Or the two methods may be combined, first boiling and shrinking them, and then soaking in iodin. These tents furnish the most desirable means of dilating the cervix in some cases, and when prepared in this way their use is free from danger.

20 Insane of Canada: Presidential Address. T. J. W. Burgess, Montreal, Canada.

15. **Difficulty of Differentiating Paratyphoid from Typhoid.**—According to Coleman, paratyphoid infections can not be distinguished from typhoid, except by the recovery from the blood of the bacillus concerned and its proper identification. He considers the term paratyphoid not only unnecessary but misleading, and suggests the advisability of considering typhoid clinically as a disease which may be caused by several members of the typhoid-colon group of bacilli.

16. **Radium Emanations.**—Phillips carried out some therapeutic experiments on seven patients with diseases of the ear, nose and throat with a properly constructed tube, the interior of which was coated with radium so that the emanations could be made use of in treatment. The method was found to be useless.

18. **Treatment of Puerperal Sepsis.**—Fischer states that the woman should receive proper care and attention before the birth of the child and that her bed should be properly prepared. Especial care should be paid to the physician's hands. The placenta and membranes should be carefully examined. The perineum should be examined for tears, and if these have occurred they should be repaired at once. As soon as there is a rise of temperature treatment should be started. Fischer emphasizes the importance of making careful digital examinations and advocates the use of a dull irrigating curette when the temperature is not reduced by douches. He calls attention to the value of normal salt solution in diluting the toxins and in aiding absorption. He prefers tube to gauze drainage in these cases, and avoids the use of gauze after the curettement. He also states that it is important to open and to drain abscesses in the pelvis as soon as they form.

23 Further Contribution to the Study of Bacilluria in Typhoid and Its Treatment with Hexamethylenamin. C. D. Easton, Boston.

22. **Lymphatic Leukemia in a Child.**—Morse's case, in a girl 3½ years old, is of interest in that it afforded an opportunity to study the development of the changes in the blood and lymph nodes during a considerable period, and that, although it was most carefully studied, the correct diagnosis could not be made until a comparatively short time before death. It shows that the character of the changes in the blood may not develop to a degree sufficient to justify a positive diagnosis for many months. It also shows that the changes in the lymph nodes may be, not only at first, but even for a considerable time, materially different from those which are usually considered to be typical of this disease. It is noteworthy that the characteristic changes in the blood and lymph nodes appeared at essentially the same time. According to Morse, the only inference that can be made from the histologic study of the tissues at different stages of the disease is that lymphatic leukemia may have its origin in a malignant growth affecting the lymphoid tissues more or less generally, and that until there is a secondary proliferation of the lymphoid cells we do not get the typical tissue picture and blood condition which is characteristic of lymphatic leukemia. It suggests that leukemia, pseudoleukemia and malignant lymphoma can not be separated as three distinct entities, and that they do not always differ characteristically in the histologic structure of their lymphoid tissues; and that the microscopic sections in these cases often will be wrongly judged in the absence of complete clinical data as regards the distribution of the process and the examination of the blood.

30 *New Method of Extracting the Internal Saphenous and Similar Veins in Varicose Conditions; Preliminary Report. W. L. Kellar, San Francisco.

25. **Use of Stomach Tube.**—Whenever possible Palier uses three vessels for obtaining the gastric contents for examination. The first few cubic centimeters he collects in one vessel; then enough for examination in a second vessel, and the remainder in a third vessel. The second vessel usually contains the fluid of the highest acidity. He seldom aspirates to obtain the gastric contents, but slips a rubber tube on the distal end of a short glass tube, the proximal end of which is inserted into a Ewald stomach tube, and by lowering the distal end the stomach contents come out by the siphon principle, especially when some pressure is used on the stomach. He believes that the stomach tube is not used sufficiently for diagnostic purposes, and cites several cases to show the utter impossibility of correctly diagnosticating and treating gastric diseases without the aid of this valuable instrument. The contraindications of introducing the stomach tube are really very few. When it is carefully and properly done, a soft rubber tube can do no harm. The classical contraindications are hematemesis, aneurism of the aorta and advanced pregnancy. Cardiac affections differ so widely in numerous respects that each case must be judged on its individual merits. In hemorrhage from the stomach, this instrument may do harm by aggravating the bleeding. In pregnancy each case should be judged on its own merits. As to aortic aneurism, while the introduction of a soft rubber tube is not likely to rupture the aneurism, yet this is liable to rupture any moment under excitement, and it is best, therefore, not to attempt the use of the tube. When the stomach can not empty itself, when there is alimentary stasis, when drainage is necessary, and when there is much mucus in the stomach, the stomach tube should be used.

26. **Dry Cups in Herpes Zoster.**—Leale emphasizes the fact that the careful and scientific application of dry cups has proved of great value in his hands in the treatment of herpes zoster, both in shortening the duration of the disease and in

ameliorating the symptoms. The dry cup should be applied over the *ganglia of the posterior roots and over the points of emergence* of the nerves involved. This is done just to the affected side of the spinous processes of vertebræ over the area determined, several cups being applied and allowed to remain long enough to insure their maximum suction power. After the first set is removed they can be reapplied if deemed necessary. Then a few cups are applied to the location of the *emergence and over the course of the nerve or nerves involved.* In this we are guided by the seat of the pain and hyperesthesia and by the location of the eruption. Leale makes it a practice to cup early in the disease, in many cases before the eruption has appeared, when, of course, it is difficult or impossible to distinguish it from a simple neuralgia. He usually finds it best to repeat the cupping once every twenty-four hours, and preferably just before the patient settles down for his night's sleep. In this way a nocturnal paroxysm of pain can often be prevented, and a good night's rest secured, which otherwise would have been impossible.

30. **New Method of Extirpating Varicose Veins.**—The operation described by Kellar should be employed to extirpate such varicose veins as have few branches, *without mutilating the patient by a continuous scar along the course of the vessel to be removed.* The vessel is exposed by a short incision near the femoral opening of the fascia lata (if the internal saphenous), is dissected free from its sheath for about one inch, and is then ligated as high up as possible. The lower end of the vein is exposed and treated in a similar manner. The vein is now cut below the proximal end and above the distal end, thus leaving the section to be removed free and ready for removal. The upper end of the section to be removed is split for about three-quarters of an inch on its anterior wall. A strong ligature is then tied to the upper end of the vein, care being taken not to include more tissue in the ligature *than will pass through the lumen of the vessel.* A wire loop or probe is then passed through the lumen of the vessel from the lower opening, and the ligature is threaded through the eye of the loop or probe, the probe is withdrawn and the ligature brought out on the surface at the point where the probe entered. Gentle traction is now made on the ligature, the edges of the vein being inverted into its own lumen by an assistant. Traction is continued until the vein is completely extirpated by being turned inside out and withdrawn from its sheath. When the internal saphenous vein is being removed a slight puckering is seen about midway between the incisions, indicating that the posterior branch of the vessel has been reached, and the latter, with another small branch often present at that point, can be ligated and incised through a small incision. After separating these branches, traction is again employed and the remainder of the vein removed. In the first patient operated on by the author only about three inches of the vein were removed, but in the second five inches were extirpated without difficulty.

34. **X-Ray Treatment of Cancer and Sarcoma.**—After having given the *x-ray a very careful trial in 68 cases of sarcoma* in almost every locality, Coley concludes that, while in certain rare cases, especially of sarcoma originating in the lymphatic glands, improvement may be very striking, going so far, in some cases, as to cause entire disappearance, there is almost always a speedy recurrence, either local or metastatic, and *that the influence of the x-rays on sarcoma is rarely, if ever, curative.* The *x*-ray exerts a powerful influence on cancer cells of all varieties, but most marked in cases of cutaneous cancer. In some cases, chiefly in superficial epithelioma, the entire tumor may disappear, probably by reason of fatty degeneration of the tumor cells with subsequent absorption. In a much smaller number of cases of deep-seated tumors, chiefly cancer of the breast and glandular sarcoma, the tumors have disappeared under prolonged *x*-ray treatment. In nearly every one of these cases, however, that has been carefully traced to final result, there has been a local or general return of the disease within from a few months to two years. *In view of this practically constant tendency to early recurrence,* furthermore, in the absence of any reported cases well beyond three years, the method should never be used except in inoperable cases, or as a prophylactic after operation, as a possible, though not yet proven, means of avoiding recurrence. The use of the *x*-ray as a preoperative measure in other than cutaneous cancer is contraindicated (1) because the agent has not yet been proven to be curative, (2) because of serious risks of an extension of the disease to inaccessible glands or to other regions by metastases during the period required for a trial of the *x*-ray.

35. **Scopolamin-Morphin Anesthesia.**—Seelig presents a series of 65 general anesthesia administrations, including abdominal and vaginal hysterectomies, operations for hernia, hemorrhoids, anal fistula, plastic operations, curettements, uterine fixations, appendicectomy, nephropexy, thyroidectomy, craniectomy, orchidectomy, etc. In every instance the patient received a hypodermic injection of scopolamin hydrobromate, grain 1/100, and morphin, grain 1/6, one-half hour before the *administration of the geenral anesthetic.* General anesthesia was induced by means of the ethyl chlorid-ether sequence administered through the Bennett inhaler, specially modified for this purpose. Seventy-seven per cent. of the patients did not vomit at all. One-third of the patients who did vomit vomited only once, and then only *from two drams to one* ounce of pure mucus. Nausea was never pronounced, except in two cases, and vomiting never occurred earlier than two hours after operation. Seeling expresses himself as thoroughly satisfied with the method.

36. **Id.**—Ries has used scopolamin morphin on 72 patients in 92 operations, with good result.

39. **Cure of Femoral Hernia.**—The cases reported by De Garmo were met with in operating in a series of 1,250 abdominal hernias. The 110 femoral hernias were in 99 patients, 83 females and 16 males. Eighty-eight patients had single and 11 had double femoral hernia. The ages of the patients ranged

between 8 and 81, the greatest number of these cases occurring between the ages of 30 and 40. In 28 patients strangulation existed at the time of the operation, and 82 patients were operated on for the cure of the hernia. Only one death occurred, that of a woman aged 70, who had a strangulated hernia and an intestinal perforation. The intestine was fastened in the wound and freely opened. The patient died of exhaustion twenty-four hours later. There was only one actual recurrence, eight months after operation, in a woman of 75. The technic of the operation employed by De Garmo is as follows: The incision should be between two and three inches long, parallel with and to the inner side of the femoral vessels. The upper angle of the wound should be well up over Poupart's ligament and extend down over the saphenous opening. When the skin and the superficial fascia are incised, usually the sac and its subperitoneal fat will come into the wound with the appearance of an encysted lipoma and, before separating the sac, it is best that this entire mass should be lifted out of its bed by thumb forceps and blunt dissection, so that its neck where it passes under Poupart's ligament shall be entirely free from its surrounding. By traction on the sac and its superimposed fat this neck may not only be freed, but it will be materially lengthened, so that when it is finally ligated and cut off it will retract within the abdominal cavity, leaving the femoral canal free of foreign tissue. This is absolutely essential to a subsequent permanent cure. The sac should be opened, and where the omentum is found adherent it should be carefully ligated, cut away, and its stump reduced to the abdominal cavity. Adherent intestine will rarely be found, but when it is the adhesions must either be broken up or, if too firm, the adherent part may be cut out of the sac and left attached to the bowel. When in doubt the latter method is by far the safer. Adherent omentum is frequently found and should be cut away after careful ligation. The sac having been entirely freed of its contents, is tied off as high as possible, while it is being forcibly drawn down by an assistant. Great care must be used to insure the perfect freedom of the neck of the sac from protruding bowel or omentum while the ligature is being placed. After tying with strong catgut (a double strand of No. 2 plain is preferred), pass the needle, which has been previously threaded with it, through the neck of the sac and tie again. This gives a double ligature anchored by perforation between the two, and prevents slipping off. When the sac is cut away the stump should be examined to be sure that no bleeding vessels remain, and not until then should the ends of the ligature be cut. When the ligature is cut the stump usually retracts within the abdomen. If this is prevented by connective tissue which has not been broken it should be carefully pushed back, leaving the femoral opening absolutely free. This opening is closed by good-sized kangaroo tendon threaded in a strong, blunt needle by pressing the end of the finger firmly into the femoral opening under Poupart's ligament, and passing the needle through the ligament on the finger-point. This perforation should be well toward the outer side of the canal and close to the femoral vein. The operator should assure himself, by pressure of the finger against the ramus of the pubes, that the vessels are out of the way, and pass the point of the needle fully down to the periosteum of the pubic bone, taking up all tissues over it. This constitutes the first stitch, but should not be tied until the others are in place. Others should then be placed in the same manner, every quarter of an inch apart, until near the spine of the pubes. Usually three or four will completely close the femoral opening. When tied down and the ends cut moderately close, the fascia should be closed in by plain catgut, to avoid a pocket in the tissues that otherwise may result, and the skin may then be closed by buried sutures of plain catgut. The wound is covered by collodion and a compress of sterilized gauze, held in place by a figure-of-eight bandage. In ten days the dressings are changed and a bandage for temporary support is applied. If healing has been complete, the patient is allowed to sit up on the tenth day and to leave the house on the fourteenth day after the operation. The bandage used after the first dressing consists of a pelvic belt, of three thicknesses of canton flannel, with a compress of gauze over the former site of the hernia, and a perineal strap to prevent its slipping up. This is to be worn for four weeks. No truss or other permanent support should be worn.

42. **New Interdental Splint.**—The splint devised by Russ is made of spring brass 3/64 of an inch in thickness. Each clamp consists of two parts, a chin-piece and a piece bent at right angles, making a long and a short arm. The chin-piece is wider at one end to prevent its slipping when incorporated into the plaster-of-Paris dressing. It is 8 cm. long and provided with a number of holes so that the plaster-of-Paris may sink into them, thus making the dressing more secure. The right-angled piece is 1 cm. wide, while the arms measure 7½ cm. and 5 cm. respectively. The end of the short arm is provided with a simple lock which fits into a corresponding lock in the chin-piece. Three or four holes should be bored into the long arm. When these two parts are locked they form a clamp which permits of easy adjustment. This adjustment is accomplished by means of a round head brass machine-screw 6 cm. in length and carrying a winged nut. This fits into holes in the long arm and the chin-piece at 1½ cm. distance from the short arm. After the clamp has been made, it should be heavily nickel plated. The clamp has been found to be applicable to thirty-five out of fifty adult jaws. For the other cases, a splint with a short arm of 5½ cm. answers. The splint is applied with the patient lying in the dorsal position on the operating table. The face is shaven clean and the fractures reduced. A thin layer of felt or layers of sheet wadding are then fitted neatly over the chin and under the jaw, extending as far back as the rami. Over this the plaster-of-Paris bandage is carefully folded, the operator rubbing the plaster well as he proceeds. The bandage is carried back on each side to the ramus, where the turns are held by an assistant or by a patient. When the jaw is well covered the splints are applied, the parts being held together by the screws and nuts. The long arms are placed directly over the molar and biscuspid teeth, extending as far back as the last molars and emerging at the corners of the mouth. The chin-pieces are pressed into the plaster. They should run along the body of the jaw. The apparatus being in position, a few more turns of the bandage are taken and the dressing completed by rubbing in dry plaster-of-Paris. Accurate coaptation is desired. When dry, the chin-pieces are detached from the interdental portions and the plaster-of-Paris dressing removed and trimmed to the desired shape. The dressing is then reapplied to the jaw. The interdental portions of the splints, together with some dental compound, such as is commonly used by dentists in taking impressions, are thrown into hot water. When sufficiently softened, the dental compound is applied along the under surface of the interdental arms, and these are quickly placed on the teeth, in the same position as in the first application, and pressed firmly down so that the splints rest on an even bed, the dental compound filling up the holes which have been bored into the long arms. The short arms are then locked to the chin-pieces, the screws reapplied, and the apparatus tightened by means of the winged nuts.

43. **Treatment of Fractures of Femur in Infants.**—A device is described by Ware which he has used with excellent results in forty cases up to the age of five years. The device consists of a right-angled isosceles triangle constructed of one strip of book-binder's pasteboard, the width of the triangle adapted to the width of the thigh. One length is obtained by measuring the trunk from the level of the lower angle of the scapula to the inguinal fold. The length of the other side of the right angle is the length of the thigh. The hypothenuse is always a few inches longer. The single strip of cardboard is then bent to the shape of the desired triangle and the overlapping edges secured by adhesive plaster. The triangle may be made more rigid by reinforcing it on all sides of this inner aspect with small pieces of cigar-box wood. The outer surfaces in contact with the trunk and thigh are to be padded with non-absorbent cotton. A muslin spica secures the triangle embracing the trunk and the thigh in a flexed position. Over the muslin bandage several turns of a dextrin bandage are placed, giving additional security to the splint. The leg is left to move freely.

ameliorating the symptoms. The dry cup should be applied over the ganglia of the posterior roots and over the points of emergence of the nerves involved. This is done just to the affected side of the spinous processes of vertebræ over the area determined, several cups being applied and allowed to remain long enough to insure their maximum suction power. After the first set is removed they can be reapplied if deemed necessary. Then a few cups are applied to the location of the emergence and over the course of the nerve or nerves involved. In this we are guided by the seat of the pain and hyperesthesia and by the location of the eruption. Leale makes it a practice to cup early in the disease, in many cases before the eruption has appeared, when, of course, it is difficult or impossible to distinguish it from a simple neuralgia. He usually finds it best to repeat the cupping once every twenty-four hours, and preferably just before the patient settles down for his night's sleep. In this way a nocturnal paroxysm of pain can often be prevented, and a good night's rest secured, which otherwise would have been impossible.

30. **New Method of Extirpating Varicose Veins.**—The operation described by Kellar should be employed to extirpate such varicose veins as have few branches, without mutilating the patient by a continuous scar along the course of the vessel to be removed. The vessel is exposed by a short incision near the femoral opening of the fascia lata (if the internal saphenous), is dissected free from its sheath for about one inch, and is then ligated as high up as possible. The lower end of the vein is exposed and treated in a similar manner. The vein is now cut below the proximal end and above the distal end, thus leaving the section to be removed free and ready for removal. The upper end of the section to be removed is split for about three-quarters of an inch on its anterior wall. A strong ligature is then tied to the upper end of the vein, care being taken not to include more tissue in the ligature than will pass through the lumen of the vessel. A wire loop or probe is then passed through the lumen of the vessel from the lower opening, and the ligature is threaded through the eye of the loop or probe, the probe is withdrawn and the ligature brought out on the surface at the point where the probe entered. Gentle traction is now made on the ligature, the edges of the vein being inverted into its own lumen by an assistant. Traction is continued until the vein is completely extirpated by being turned inside out and withdrawn from its sheath. When the internal saphenous vein is being removed a slight puckering is seen about midway between the incisions, indicating that the posterior branch of the vessel has been reached, and the latter, with another small branch often present at that point, can be ligated and incised through a small incision. After separating these branches, traction is again employed and the remainder of the vein removed. In the first patient operated on by the author only about three inches of the vein were removed, but in the second five inches were extirpated without difficulty.

66. **Submucous Window Resection of Nasal Septum.**—Killian describes, in detail, the operation devised by him and first reported in 1899. Two hundred and twenty patients have been operated on by Killian and his assistants according to this method. The submucous resection of the septum can be both temporarily and permanently contraindicated. The latter applies to people of advanced age, unless there are important reasons for interference. Small children are also not good subjects for such an operation as their nasal proportions are small and the narcosis is not so satisfactory. From 12 years on, however, the operation generally can be performed. Various chronic constitutional diseases are contraindications to operation. In pulmonary tuberculosis, one should operate only during the early stages, and then only on well-nourished patients with a good prospect of a standstill or healing of their disease. Killian never operates on patients with temporarily healed nasal lupus, because of the danger of a recurrence and an extension of the process. The operation is temporarily contraindicated on all patients with an acute process in the region of the nose, especially an acute rhinitis. If there exists a decided purulent secretion it is best to put off the operation until there is a marked improvement, unless urgent reasons for operating are present. Patients suffering with tertiary syphilitic lesions in the nose must not be operated on until healing has taken place and a long time has elapsed without recurrence. The essential feature in the technic of the operation is that by means of a long speculum, Killian makes a median space between the two mucous layers of the septum, in which he can operate as easily as in the inside of either nasal cavity. The entrance to this space is the incision which becomes rectangular in shape through the use of the speculum. All the other parts of the operation group themselves about this fundamental idea. The operation is completed in about twenty minutes.

68. **Pathogenesis of Epididymitis Gonorrhoica.**—Summing up the results of their observations and experiments, Oppenheim and Loew find certain peculiarities in the origin of this affection. As causes they found besides violent muscular exertion, mechanical or chemical irritations of the posterior urethra, and ejaculations of semen. In a great number of cases the inflammation does not involve the vas deferens, but localizes itself in the tail of the epididymis, later affecting the other parts of the epididymis and also the vas deferens. The rapidity of the appearance could not be explained, but the experiments and microscopic examination speak against a lymphatic transportation. These properties are explained directly by supposing that the transportation of the process into the epididymis is caused by retroperistalic movement of the vas. Such movement is observed in rabbits, guinea-pigs and man, and it is possible to produce it by all the factors which could cause an epididymitis, such as violent trauma, and irritation of the caput gallinaginis. It is an important factor in every ejaculation. Furthermore, it is possible to produce epididymitis experimentally in rabbits, if cocci are present in the posterior urethra, by this retro-peristaltic movement, quite analogous to human gonorrheal epididymitis. As to the theory of the affection, the authors emphasize that the application of instruments of any kind is contraindicated in acute posterior urethritis, and that every necessary exploration of the prostate must be made with great caution. The patient must refrain from sexual excitement and violent muscular exertion. The more severe the posterior urethritis, the greater the danger. If epididymitis exists on one side, all local treatment of the posterior urethra should be suspended because there is danger of the other epididymis becoming affected. In subacute and chronic posterior urethritis, when gonococci are still present, the use of irritating injections should be avoided.

48. **Chronic Nontuberculous Joint Disease.**—Jones cites thirty cases of monarticular joint disease of nontuberculous origin, and representing four types: 1. Cases characterized principally by hypertrophy of the joint. 2. Cases characterized by atrophy of the joint. 3. Cases of undoubted joint infection. 4. Cases of probable periarthritis in which infection was uncertain and in which no permanent changes in the joint could be definitely shown. Of the hypertrophic variety there were seven cases, three affecting the spine, two the hip, and one each the knee and elbow. All the patients were men between 35 and 50 years of age, none of them arteriosclerotic. The duration of the disease was from 12 years to a little less than one year. In all but one case the joints involved were those subject to weight bearing. In only one (the elbow) could a definite primary cause (syphilis), be assigned; trauma seemed to bear a definite relation to the disease in only one case. In all save one the disease had been progressing steadily for the worse. The treatment consisted mainly in the use of jackets in the spine cases, coupled with rest in bed several weeks in two on account of sciatica. A spica, a high sole in one of the hip cases, and the use of a cane in another; partial fixation of the knee in a leather support, and the administration of potassium iodid and biniodid of mercury in the case in which the elbow was affected, was the treatment employed in the other cases. This latter case and in one of the spine cases the patients can be said to be well. In three cases (a spine, a hip and a knee) the patients have been relieved, and in two (a spine and a hip), practically no change has taken place. Of the second type there was but one case, occurring in a woman of 36; the disease having existed six years. The left knee was ankylosed in the fully extended position, due to confinement in plaster for two years. Forcible manipulation under anesthesia resulted in a movable joint with about 60 degrees of flexion allowed. There were five cases of type 3. Two of these were cases of spondylitis in young adults, one developing directly after childbirth and coincident uterine infection, and the other occurring in a young man. The first patient recovered in four months after the jacket and brace treatment. The other patient died of typhoid, the spinal affection probably taking its origin in the typhoid. The remaining cases had definite relation to gonorrhea, the joints affected being the hip, knee and ankle. The remaining cases (seventeen in all) belonged to type four. In all, except one, the shoulder was involved; the exceptional case being of the elbow. The affection is an inflammatory disease of the shoulder, characterized by severe pain referred to the anterior part of the joint; the point most painful to pressure being the anterior portion of the head of the humerus. The pain often radiates down the arm or across the scapula. Muscular spasm is pronounced in the early stages, being more severe at night. Final results in these cases were quite satisfactory.

49. **Operative Treatment of Bone Tuberculosis.**—Painter believes that there is a very definite field for radical surgery in tuberculous disease; that this field can be very exactly outlined by certain specific rules to which it is not possible often to make exception; that there would be a great deal less needed of consideration of operative surgery than there is now if cases were properly managed through the earlier stages of the disease; that tuberculosis in the bones and joints is tuberculosis and is not simply joint disease; that the principles which underlie the successful treatment of tuberculosis, pulmonary or otherwise, as certainly underlie the treatment of this disease in the bones and joints as they do anywhere else, and that one who attempts this kind of surgery without being in a position to follow out the treatment other than operative had much better forego the operative measures in the majority of instances and give his patients the benefit of nature's restorative measures. Joints which have suffered from tuberculosis infection in childhood, relapsing in adult life, yield the best results if ankylosis can be secured in a good position. If motion is present, together with deformity, the deformity should be corrected, provided there are as many as twenty-five degrees of motion; if less motion than this, and deformity exists, it should be corrected and ankylosis secured at the same time. If deformity is present with ankylosis, the ankylosis should be left alone, and the deformity overcome. If motion without deformity is present and this motion is less than the above mentioned number of degrees, it is safer to secure ankylosis, as the irritation of so few degrees of motion tends to stir up latent disease. This would be called for, of course, unless there were symptoms of oft-repeated joint strain or active disease.

51. **The X-Ray In Bone Tuberculosis.**—Peckham reports five cases of bone tuberculosis, treated with the *x*-ray, as an auxiliary to other treatment, three times a week. All the cases were suppurative, two of them being considered desperate. One is put down as a failure, although even here there was slight temporary improvement, two were markedly improved, while the two desperate cases were practically saved from amputation, one being a knee, the other an elbow.

56 Ascending Neuritis. W. J. Herdman, Ann Arbor.
57 Psychotherapeutics of Neurasthenia. J. C. Solis, Ann Arbor.

55. **Kidney Surgery and Utility of Diagnostic Aids.**—As the result of careful study of personal cases, and an examination of the literature on the subject, Chetwood concludes as follows: In profuse suppuration of the kidney, or multiple abscess of either kidney, there is a question whether nephrotomy or nephrectomy should be primarily resorted to—a question that can only be properly decided on the merits of each case involved. There is no doubt that a very small remnant of kidney structure may perform a certain amount of renal function; and primary nephrotomy and drainage will often give time to decide this question more satisfactorily; and some patients may sustain a secondary better than a primary nephrectomy. General systemic infection may be considered in indication for both primary and secondary nephrectomy. As to lithiasis: The same rules may be applied in the treatment of the kidney itself as are employed in suppuration with renal calculi. There is no question that nephrotomy is the operation indicated in aseptic lithiasis. As to tuberculosis of the kidney: Even when there is a vesical and pulmonary involvement the only resort of reasonable promise is nephrectomy when the integrity of the opposite kidney is established. Generally speaking, in urogenital tuberculosis, removal of the primary focus, which is frequently in the kidney, is likely to exercise an inhibitory influence on the distal implication—as, for instance, vesical involvement. In subcutaneous injury to the kidney, where there is evidence of a perirenal tumor with hematuria, immediate exploratory incision should be employed and, when possible, suture and tamponade should be resorted to. Where the vessels or ureter have been ruptured and the laceration of the kidney is extensive, or where the injuries are complicated by beginning or progressing suppuration, total nephrectomy may be necessary. Conservative operation is favored by a majority of authors and symptomatic treatment is considered effective in mild cases. A safe rule is to resort to exploratory incision in all doubtful cases and to perform extirpation only when necessary. Above all, too much stress cannot be laid on the importance of the refinement of diagnosis and the advantage of having recourse to the

most improved methods of investigation. The great and progressive reduction of mortality is attributable to diagnostic improvement. Marked differences in mortality between different operators may be explainable by the failure to employ the latest diagnostic resources. Chetwood says that what the compass, the sextant, and the chart are in governing the route of the navigator, so are the microscope, the cystoscope and the x-ray in directing the course of the surgeon through the obscure realm of kidney surgery.

67 *Submucous Resection of the Nasal Septum, New Technic with the Author's Swivel Knife, Reducing the Average Time of the Operation Several Minutes. W. L. Ballenger, Chicago.

66. **Submucous Window Resection of Nasal Septum.**—Killian describes, in detail, the operation devised by him and first reported in 1899. Two hundred and twenty patients have been operated on by Killian and his assistants according to this method. The submucous resection of the septum can be both temporarily and permanently contraindicated. The latter applies to people of advanced age, unless there are important reasons for interference. Small children are also not good subjects for such an operation as their nasal proportions are small and the narcosis is not so satisfactory. From 12 years on, however, the operation generally can be performed. Various chronic constitutional diseases are contraindications to operation. In pulmonary tuberculosis, one should operate only during the early stages, and then only on well-nourished patients with a good prospect of a standstill or healing of their disease. Killian never operates on patients with temporarily healed nasal lupus, because of the danger of a recurrence and an extension of the process. The operation is temporarily contraindicated on all patients with an acute process in the region of the nose, especially an acute rhinitis. If there exists a decided purulent secretion it is best to put off the operation until there is a marked improvement, unless urgent reasons for operating are present. Patients suffering with tertiary syphilitic lesions in the nose must not be operated on until healing has taken place and a long time has elapsed without recurrence. The essential feature in the technic of the operation is that by means of a long speculum, Killian makes a median space between the two mucous layers of the septum, in which he can operate as easily as in the inside of either nasal cavity. The entrance to this space is the incision which becomes rectangular in shape through the use of the speculum. All the other parts of the operation group themselves about this fundamental idea. The operation is completed in about twenty minutes.

71 Syringe Versus the Irrigator in Gonorrhea. F. C. Valentine and T. M. Townsend, New York.

68. **Pathogenesis of Epididymitis Gonorrhoica.**—Summing up the results of their observations and experiments, Oppenheim and Loew find certain peculiarities in the origin of this affection. As causes they found besides violent muscular exertion, mechanical or chemical irritations of the posterior urethra, and ejaculations of semen. In a great number of cases the inflammation does not involve the vas deferens, but localizes itself in the tail of the epididymis, later affecting the other parts of the epididymis and also the vas deferens. The rapidity of the appearance could not be explained, but the experiments and microscopic examination speak against a lymphatic transportation. These properties are explained directly by supposing that the transportation of the process into the epididymis is caused by retroperistalic movement of the vas. Such movement is observed in rabbits, guinea-pigs and man, and it is possible to produce it by all the factors which could cause an epididymitis, such as violent trauma, and irritation of the caput gallinaginis. It is an important factor in every ejaculation. Furthermore, it is possible to produce epididymitis experimentally in rabbits, if cocci are present in the posterior urethra, by this retro-peristaltic movement, quite analogous to human gonorrheal epididymitis. As to the theory of the affection, the authors emphasize that the application of instruments of any kind is contraindicated in acute posterior urethritis, and that every necessary exploration of the prostate must be made with great caution. The patient must refrain from sexual excitement and violent muscular exertion. The more severe the posterior urethritis, the greater the danger. If epididymitis exists on one side, all local treatment of the posterior urethra should be suspended because there is danger of the other epididymis becoming affected. In subacute and chronic posterior urethritis, when gonococci are still present, the use of irritating injections should be avoided.

3. *Experimental Contribution to the Treatment of Cholelithiasis. W. Bain.

3. Cholelithiasis.—The experiments described by Bain were undertaken to ascertain the changes undergone by gallstones introduced into the normal gall bladder, and the fat of such calculi when cholecystitis was artificially produced. Various substances were also given to dogs with cholecystitis in the hope of finding a remedy. The operative procedures were as follows: After the animal was anesthetized the skin of the abdomen was prepared, and a median incision two or three inches long was made from the xyphoid downward. The gall bladder was drawn forward and held by Spencer Wells forceps. It was then incised, the bile soaked up and the stones inserted. Sutures were applied in the usual way, and in a majority of the experiments the gall bladder was stitched to the abdominal wall; in others it was dropped back into the abdominal cavity. When Bain wished to set up cholecystitis, a culture of the *Bacillus coli communis* in normal saline solution was injected into the gall bladder before the last stitch was inserted. Bain found that gallstones introduced into a normal gall bladder become dissolved within a comparatively short space of time, in about eight or nine weeks. That when a mild degree of cholecystitis is set up gallstones inserted into the gall bladder do not disappear, although there is always a reduction in weight. That the introduction of various drugs does not appear to have any effect in resolving calculi introduced into a gall bladder the mucous membrane of which is inflamed. That during a course of the sulphur water gallstones become disintegrated in cases of cholecystitis experimentally induced. That in the treatment of artificially produced cholelithiasis a preparation containing hexamethylenamin has a pronounced effect in causing dissolution of the calculi. That in regard to the action of barium chlorid further experiments are necessary to determine its rôle in experimentally-produced cholelithiasis.

6. Spa Treatment of Circulatory Disorders.—Williams discusses the therapeutic value of the various European spas, particularly Bad Nauheim. He says that the Nauheim treatment can be obtained elsewhere than at Bad Nauheim and that this spa possesses many unpleasant features and some decided disadvantages. From the points of view of climate and accessibility Nauheim is by no means a place to which a cardiac patient should be advised to go. The treatment by Nauheim baths is quite unsuited to the great majority of cardiac disorders, and its indiscriminate recommendation, even when dilatation is the most prominent objective feature, is by no means free from danger. In deciding on the respective claims of the numerous spas at which cardiovascular diseases may be treated, it is necessary to take into consideration various factors. In general, it may be said, that any spa at which gout is properly treated is, potentially at any rate, a spa suitable to a cardiac lesion. It must be remembered, however, that physicians at such resorts are not, as a rule, in the habit of dealing with cardiac disorders; and, furthermore, that certain health resorts, the waters of which are well adapted to the gouty, have specialized in troubles of the cardiovascular system. To get the best results from spa treatment, patients should be treated in the earliest stages, in the stage of arterial spasm, which has not as yet led to organic change.

8. Behavior of Leucocytes in Malignant Growths.—Farmer, Moore and Walker give an account of observations relating to the peculiar behavior of leucocytes in very early examples of carcinoma in various parts of the human body. The phenomena described appeared to be mainly, if not entirely, restricted to cancer in its earliest stages and did not occur in older growths, in metastases, or in grafts introduced into other individuals. In a rectal carcinoma the size of a bean it was found that there was a very distinct zone of transition from the normal to the cancerous element round the periphery of the tumor. Immediately within the outer zone the leucocytic crowding was most strikingly apparent, and in a number of cells it was easy to discern the presence of leucocytes which had invaded the epithelial cells, where they stained readily as an inclusion. This phenomenon did not occur in the adjacent healthy tissue nor in inflammations produced artificially. The most important, as well as the most singular, feature lies in the fact that neither the leucocyte nor the invaded tissue cell appeared to be affected injuriously. In many instances it was found that both the leucocyte and the tissue cell were dividing mitotically at the same time. The authors believe that a mixture of the chromosomes derived from the leucocyte and tissue cell, respectively, is distributed between the daughter nuclei resulting from the mitosis. In this way a complete disturbance of the normal chromosome constituents of the cell will be effected and the distribution must be of a qualitative as well as of a quantitative character. What its relation to the ultimate reduction that occurs in neoplastic cells may be is a subject for further investigation.

19 Work of the Pancreas. W. L. Brown.

14. Intestinal Obstruction After Pelvic Operations.—The object of Corner's paper is to enunciate two propositions: First, the small intestines are only too prone to become adherent to the uterine stump left after supravaginal hysterectomy; and, second, that the reasons for this are to be found in the nature and technic of the operation as it is usually performed. The operation which stands pre-eminent among all others in causing this complication is supravaginal hysterectomy. The presence of the uterine stump among the small intestines undoubtedly disposes them to become adherent. Corner suggests that there are means of obviating these occurrences. The stump should be sealed off quickly and in such a manner that the peritoneal edges do not gape. The best method of suturing a uterine stump consists of deep stitches, with intermediate ones, taking up little more than peritoneum, in between. Stitches must not be tied too tightly, but just sufficiently to sink the thread in a groove in the stump. A long posterior flap is the one which is most useful. It covers the cervical stump of the amputated uterus, a continuous suture fixes it to the bottom of the uterovesical pouch, at the same time anteverting the stump so that it covers and protects the line of stitching from the intestines, preventing them from becoming adherent.

75 Beitrag zur Aetiologie und Behandlung der multiplen Sklerose. G. Nespor.
76 Ueber den Fusohlenreflex und das Babinskische Phänomen bei tausend Kindern der ersten Lebensjahre (plantar reflex and Babinski in children). A. Bickel.

57. Differentiation of Antemortem and Postmortem Burns.—Reuter believes that it is impossible to determine by examination of the cadaver whether a burn of the first, second or third degree occurred during life or after death. The viscera should be examined for carbon particles and evidences of carbonic oxid asphyxiation. Serous blebs may form on edematous parts, hence they do not indicate that the burn occurred during life.

63. Habitual Luxation of Patella.—Ruediger's patient was a girl 10 years old, who sustained a severe injury of the patella which was followed by a habitual luxation of this bone, the result of improper treatment. The knee joint was very painful and at times became swollen. The patient was operated on according to the method of Ali Krogius, which the author believes to be the ideal operation for this class of cases. The patient made a perfect recovery.

64. Operative Treatment of Subphrenic Abscesses.—Clairmont and Ranzi cite *ten cases, seven males* and three females, most of whom were between the ages of 20 and 30, in three cases the abscess emptied itself through the appendix. In eight cases the abscess was situated on the right side; in two on the left side. In one case the abscess was situated between the stomach, spleen and colon. All the abscesses were intraperitoneal. Tympanites appeared in five cases. In one case it was caused by the *Bacillus paracoli aerogenes*. In diagnosing this condition the authors found the Roentgen ray of value, particularly in cases showing obscure symptoms. Fluoroscopy was also used successfully. Two of the patients operated on died, one on the eighteenth day from peritonitis. The other case offered little hope of a successful outcome at the time of operation. Seven patients made a complete recovery. Two of the patients were operated on according to the method of Grueneisen. In four cases the abscess was opened by making an incision in the chest wall along the margin of the ribs, without entering the pleura. In the remaining four cases the abscess was evacuated through the lumbar region.

65. **Negri Bodies in Rabies.**—Schiffmann found these bodies in eight rabid dogs and in two men. He divides them into three kinds: 1. Large, irregularly formed bodies containing a large number of sharply-defined ringlike structures. 2. Forms containing only one variety of these internal structures. 3. Forms having a homogeneous structure. He says that it is impossible to state whether these bodies represent parasites or a degeneration of the cell protoplasm. It is just as possible that the Negri bodies are the result of the infection as that they are the cause of rabies.

66. **Id.**—*Maresch confirms the work of other investigators* and urges further experimentation for the purpose of determining definitely the nature of these so-called cell inclusions.

72. **Spinal Analgesia.**—Preindlsberger cites his experiences in the production of spinal analgesia. He uses a metal syringe, which may be taken apart. It has a capacity of one gram. The injection is made with the patient in Bier's side position. Preindlsberger has operated under spinal analgesia in 345 cases; all but 8 of these have been followed. A complete list is given of all the cases. Only one of his patients suffered from shock and collapse, although 6 others were slightly indisposed.

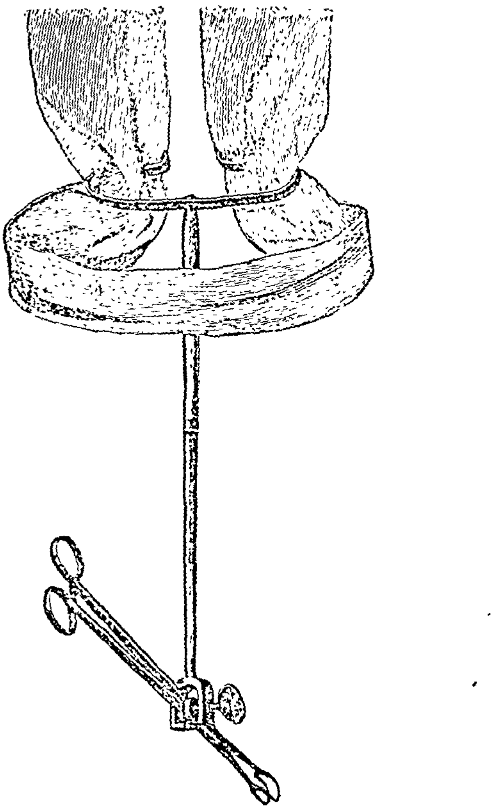
84 (No. 31.) *Blutuntersuchungen bei Unterleibsleiden der Frauen, besonders bei Uterusmyomen (blood examinations) in women ill with pelvic diseases, especially myoma of uterus). G. Klein.
85 *Zwei Assistenz ersetzende Instrumente (instruments taking the place of two assistants). C. Rindfleisch.

77. **Pregnancy and Carcinoma Recti.**—A case of carcinoma recti complicating pregnancy, occurring in a woman 18 years old, is reported by Nijhoff. The carcinoma was inoperable. The pregnancy had advanced to the seventh month. At the beginning of the eighth month she developed symptoms of sepsis and died in a few days after the infant had been delivered by forceps. The child was placed in an incubator. Nijhoff refers to 22 published cases. In closing he says that if the child is not viable the operator must choose between induction of labor and waiting until the child is viable. He believes that the former is preferable, inasmuch as it is extremely probable that during the time of waiting an operable tumor may be converted into an inoperable tumor.

79. *Cesarean Section at Schauta's Clinic.—Neumann reports* on 175 cases of Cesarean section in Schauta's clinic during the past twenty years. Of this series 14 patients died, a mortality of 8 per cent. *Six of these patients, however, did* not die as the result of the operation, but from other causes, *thus leaving only* 169 cases with 8 deaths, a mortality of 4.7 per cent. As for the babies, 165 were born alive, 9 were born dead and one was asphyxiated during delivery and died one-half hour afterward. In 158 of these cases a contracted pelvis was the indication for operation. In 6 cases there were stenoses of the soft parts; in 3 cases tumors of the adnexa, and in one case a malignant tumor of the pelvis obstructed the outlet. Five cases of eclampsia and 2 of septic endometritis were also indications for operation. In 47 cases the pelvic contraction was absolute. These patients were operated on as follows: Conservative longitudinal incision (including 2 cases of osteomalacia), 27 cases; longitudinal incision with castration (osteomalacia), 1; conservative transverse fundus incision, 1; transverse fundus incision with castration (osteomalacia), 3 cases; transverse fundus incision with resection of tubes, 5 cases; Porro operations, 9 cases; in 7 cases the *uterus was opened by longitudinal incision, in* 2 *by a longi*tudinal incision over the fundus (two of these cases were not positively aseptic and 7 patients had osteomalacia). In one case *of osteomalacia hysterectomy was done after the* Cesarean section. In the 111 cases of relative contractions of the pelvis the following procedures were carried out: Ninety conservative longitudinal incisions; 1 conservative longitudinal incision over the fundus; 1 longitudinal incision with resection of the tubes; 12 conservative transverse fundus incisions, and 7 transverse fundus incisions with resection of tubes. Among the operations performed on the 6 patients with stenosis of the soft parts were 2 conservative longitudinal incisions (1 carcinoma cervicis and 1 congenital stricture of the vagina); 1 transverse fundus incision with resection of the tubes (cicatricial stenosis of the vagina); 2 Porro operations with longitudinal incisions (cicatricial stenosis of the vagina), and one Porro operation with transverse fundus incision (carcinoma cervicis). In the 5 cases of eclampsia a Porro operation with longitudinal incision was done once, and the conservative longitudinal incision four times. In the total number of cases the Porro operation was done 15 times, hysterectomy once, and ablation of the adnexa 18 times.



Forceps and bandage holder (see abstract 85, page 745).

83. **Method of Extracting Severed Head from Uterus.**—The method employed by Bensinger consists in applying a pair of bullet forceps to the cervical vertebræ, and tamponing the uterus and cervix with iodoform gauze, and the vagina with cotton. A piece of string was attached to the forceps, passed

over the foot of the bed and weighed about four pounds—a sort of tension extraction. In the cases reported there was uterine inertia, but the method adopted proved successful, the cervix being dilated sufficiently to allow of the passage of the head.

84. **Blood Examinations in Pelvic Disease.**—Klein emphasizes the value of blood examinations in women as a means of diagnosis and prognosis in cases of pelvic disease, especially in myoma of the uterus, and cites several cases.

85. **New Instruments.**—Rindfleisch has devised two instruments to take the place of assistants, thus permitting the surgeon to do minor gynecologic operations at the patient's home in cases of necessity. One is a forceps and bandage holder (p. 744), consisting of an open metal loop, with the ends turned in, attached to a rod, at the other end of which is a set-screw. The rod is made in two parts so that it can be shortened or lengthened as may be necessary. The forceps are held in place by means of the set-screw, whereas the bandage is held by the loop. The second instrument is a self-retaining speculum patterned after the Sims model, to which a 350 gram weight is attached.

91 *Ei [illegible] pospadia penis und penoscro- [illegible] inealschnitte (single sitting [illegible] and penoscrotalis with preliminary perineal section). H. Vulliet.

87. **Ligature Ring.**—Stieda describes a so-called ligature ring devised by v. Bramann. It consists of three parts, a ring provided with an adjustable clutch and carrying a firmly fixed rod on which revolves a metal spool, on which the ligature is wound. Over this ligature spool a perforated metal cap is pushed, completely covering the spool. The end of the ligature passes through one of the perforations in the cap. The ring is placed on a finger of the left hand, thus doing away with useless handling of the ligature. The ring is easily sterilized. Stieda prepares the silk by immersing it in ether for twenty-four hours, and then boiling it for half an hour in a 3 per cent. carbolic acid solution. It is then wound on the spool and boiled again for half an hour in the 3 per cent. carbolic acid solution.

88. **Semidorsal Position in Operation for Perityphlitis.**—Foersterling, Schlange's assistant, speaks of the latter's custom of placing his patients, after having opened the abdomen, in a left semidorsal position, supporting the right shoulder and buttock so that the body lies from 12 to 15 cm. above the table. This position permits of much more rapid operating by keeping the intestines out of the field and thus enabling the operator to find the appendix quite readily. This position is said to possess all the advantages of elevating the pelvis and none of the disadvantages of the latter method.

91. **Operation for Hypospadia Penis and Penoscrotalis.**—Vulliet's method consists of a preliminary perineal incision and a small urethral incision through which an elastic catheter is inserted into the bladder, thus providing for the outflow of the urine. The penile urethra is then repaired, the choice of method being immaterial. After a few days the perineal catheter is removed and the wound allowed to granulate. This method provides for a one-sitting operation—a distinct advantage.

131 Children's Asylums.—Weiteres von deutschen Landerziehungsheimen. O. Katz.

104. **Fatigue Toxin and Antitoxin.**—Through a series of experiments Weichardt found that fatigue toxin is formed in large quantities from muscle albumin by continuous action of the muscles in an atmosphere containing a lessened amount of oxygen. The amount of fatigue toxin is increased by treating it with reducing substances, such as sodium sulphate. Toxins which reduce albumin may also be formed from the placenta, the brain, etc. The antitoxin obtained by repeated injection of fatigue toxin forms a group reaction with these albumin-reducing toxins. Animals injected with both the toxin and the antitoxin are capable of greater resistance to fatigue than animals not so injected.

108. **Celluloid Intubation Tubes.**—Reich has made use of celluloid tubes for intubation purposes. They are light in weight, present a perfectly smooth exterior and interior, are elastic, less likely to produce pressure necrosis, and permit of a large lumen with the thinnest possible wall consistent with strength and firmness. They are disinfected readily by washing in running water and immersion, for a short time, in a weak carbolic acid solution.

most of whom were between the ages of 20 and 30, in three cases the abscess emptied itself through the appendix. In eight cases the abscess was situated on the right side; in two on the left side. In one case the abscess was situated between the stomach, spleen and colon. All the abscesses were intraperitoneal. Tympanites appeared in five cases. In one case it was caused by the *Bacillus paracoli aerogenes*. In diagnosing this condition the authors found the Roentgen ray of value, particularly in cases showing obscure symptoms. Fluoroscopy was also used successfully. Two of the patients operated on died, one on the eighteenth day from peritonitis. The other case offered little hope of a successful outcome at the time of operation. Seven patients made a complete recovery. Two of the patients were operated on according to the method of Grueneisen. In four cases the abscess was opened by making an incision in the chest wall along the margin of the ribs, without entering the pleura. In the remaining four cases the abscess was evacuated through the lumbar region.

65. **Negri Bodies in Rabies.**—Schiffmann found these bodies in eight rabid dogs and in two men. He divides them into three kinds: 1. Large, irregularly formed bodies containing a large number of sharply-defined ringlike structures. 2. Forms containing only one variety of these internal structures. 3. Forms having a homogeneous structure. He says that it is impossible to state whether these bodies represent parasites or a degeneration of the cell protoplasm. It is just as possible that the Negri bodies are the result of the infection as that they are the cause of rabies.

66. **Id.**—Maresch confirms the work of other investigators and urges further experimentation for the purpose of determining definitely the nature of these so-called cell inclusions.

72. **Spinal Analgesia.**—Preindlsberger cites his experiences in the production of spinal analgesia. He uses a metal syringe, which may be taken apart. It has a capacity of one gram. The injection is made with the patient in Bier's side position. Preindlsberger has operated under spinal analgesia in 345 cases; all but 8 of these have been followed. A complete list is given of all the cases. Only one of his patients suffered from shock and collapse, although 6 others were slightly indisposed.

104. **Fatigue Toxin and Antitoxin.**—Through a series of experiments Weichardt found that fatigue toxin is formed in large quantities from muscle albumin by continuous action of the muscles in an atmosphere containing a lessened amount of oxygen. The amount of fatigue toxin is increased by treating it with reducing substances, such as sodium sulphate. Toxins which reduce albumin may also be formed from the placenta, the brain, etc. The antitoxin obtained by repeated injection of fatigue toxin forms a group reaction with these albumin-reducing toxins. Animals injected with both the toxin and the antitoxin are capable of greater resistance to fatigue than animals not so injected.

108. **Celluloid Intubation Tubes.**—Reich has made use of celluloid tubes for intubation purposes. They are light in weight, present a perfectly smooth exterior and interior, are elastic, less likely to produce pressure necrosis, and permit of a large lumen with the thinnest possible wall consistent with strength and firmness. They are disinfected readily by washing in running water and immersion, for a short time, in a weak carbolic acid solution.

133. **Roentgen Treatment of Hypertrophied Prostate.**—Carabelli and Luraschi state that the experiments related in this article were commenced in May and continued through August of 1904, and that they have waited a full year before reporting them in order to ascertain the remote results. No communications in regard to Roentgen treatment of hypertrophied prostate had been published when they undertook it in two cases. The patients were 60 and 65 years of age respectively. They were placed on a sloping table, the surrounding parts carefully protected and the Roentgen rays applied to the perineum, with the tube from 20 to 25 cm. from the skin. Carabelli did not think it necessary to introduce the tube into the rectum as the atrophying action of the Roentgen rays on deep-laying glands like the ovary, spleen and lymphatics has been amply established. It is evident also that the action of the rays on the prostate is more pronounced when the hypertrophy is in the first stage, before the gland has undergone fibrous degeneration. The relief of the pains was marked from the very first. In one case the paresthesia and oppression in the perineum were accompanied by difficulty in urinating and palpation revealed moderate hypertrophy of the prostate. The rays were applied fifteen times, at first two or three times a week and then once a fortnight. The sensory symptoms vanished and urination became very much easier. In the second case the prostate was much enlarged and hard, and there were about 200 gm. of residual urine and evidences of chronic catarrh of the bladder. After six applications of the Roentgen rays the urine became clearer, the pains had subsided, urination was much easier and the residual urine was only 40 gm. After the tenth application there were only 10 c.c. of residual urine, and the patient was dismissed as practically cured. The current was applied for from three to seven minutes at a sitting in the first, and for ten minutes in the second, the current 1.5 amperes, 100 volts. The patients have been examined during the year and recently and the improvement has been found to be permanent.

143. **Return of Function in Hydronephrotic Kidney.**—Bozzi has been conducting considerable experimental research on this subject and is convinced that surgical intervention should be early in case of hydronephrosis, even if the symptoms are not disturbing. It will forestall the development of permanent changes in the tissues of the kidney which otherwise become irreparable. It will also prevent possible infection of the kidney by way of the blood. He cites some suggestive cases to show the importance of these points. In some the cystoscope and catheterization of the ureters showed limpid urine from one kidney and purulent from the other. The kidney with the purulent process was extirpated under the conviction that its mate was sound, but anuria and death soon followed. The hydronephrotic kidney after a conservative operation gradually regains its functional capacity, the extent of restitution being in inverse proportion to the duration of the process. Bozzi's experiences have shown that the microscope discloses much better functional conditions than would be supposed from the macroscopic appearance. Consequently there is every reason to retain the hydronephrotic kidney by a conservative operation.

146. **Pelvic Peritonitis.**—In this article Lizano calls attention to the often forgotten fact that in the beginning of pelvic peritonitis vaginal examination reveals little or nothing beyond a greatly increased sensibility to pain, and that at this stage of the disease the diagnosis must be made from the abdominal symptoms and from the general condition of the patient. After three or four days, he states, when the nausea and vomiting have to a certain extent subsided, careful bimanual palpation reveals the presence of an exudate filling the cul-de-sac of Douglas and occasionally projecting into the vagina. Lizano states that in some cases careful palpation will enable the physician to make out the upper border of the exudate in the hypogastric region and sometimes a zone of induration. Occasionally instead of fluctuation a solid mass will be felt. When the lesion is very extensive the uterus may be fixed in the pelvis by a mass of plastic exudate causing pain on pressure and obstructing the rectum at the level of the uterosacral ligaments. The progress of the disease varies according to the nature and intensity of the infection. In peritonitis following the puerperium or pyosalpinx, the inflammation is generally circumscribed and confined to the pelvis, and the exudate is usually walled off by adhesions. Should the abdominal peritoneum become involved, however, the constitutional symptoms—vomiting, meteorism, etc.—are aggravated. In purulent peritonitis Lizano advises evacuating the pus through the vagina. If evacuation is complete, he says, cure is possible, but if it is incomplete, fistulas of various kinds may result, with death later from septicemia. Lizano discusses the points of differential diagnosis between acute and chronic peritonitis, hematocele, and the gonorrheal and tuberculous forms of peritonitis.

149. **Palpebral Chancre.**—A young woman, aged 29, consulted Leoz for the relief of a tumor of the eyelid. The tumor was round, hard and indurated, and though the patient presented no other symptoms of the disease, a diagnosis of syphilis was made. This diagnosis was confirmed later by a colleague in a general hospital. Leoz reports this case because of the extreme rarity of chancre in this region and the likelihood of mistaking it for a chalazion or even for a simple blepharitis. In 25,000 cases of eye diseases Leoz has only seen two like this and one chancre of the conjunctiva.

150. **Plastic Operations on the Cheek.**—Goyanes states that the most frequent causes of loss of tissue in the cheek are trauma, gangrene, and operations for the removal of carcinoma. He says that unless this loss is corrected by surgical means there is likely to be considerable resulting deformity, which generally takes the form of cicatricial contraction of the muscles of the lower jaw. In this article he reports the case of a patient aged 22, who entered the clinic of D. A. San Martin in May, 1904. According to the patient's statement, he had had a malignant pustule on the inside of the left cheek at the age of 7, which was treated with the Paquelin cautery. The resulting contraction of the muscles prevented him closing his mouth. The patient was anesthetized and a flap was formed of the skin of the neck. This flap was inverted and turned toward the buccal cavity and sutured in place with catgut. The cosmetic effect was very good and the patient was able to close his mouth and to masticate his food. Goyanes describes the operation in detail and reviews the literature on the subject. Goyanes describes the operation in detail, emphasizing the necessity for avoiding wounding Steno's duct. He also reviews the literature on the subject.

THE OCULAR SYMPTOMS OF AFFECTIONS OF THE ACCESSORY SINUSES OF THE NOSE.*

WILLIAM CAMPBELL POSEY, M.D.
PHILADELPHIA.

A few years ago there were but few specialists in the practice of diseases of the eye who did not combine with the treatment of affections of that organ that of diseases of the throat, nose and ear, also. By reason of the development of each of these several branches of medicine and the increased demands which have been made in consequence on the time and resources of those practicing them, the continuance of this combination of specialties has seemed no longer desirable and physicians are confining themselves more and more to but one subject. While this course is surely to be commended, and while the various departments of medicine will undoubtedly attain their highest development in this way, it should be remembered that the manner in which specialists have divided the body is purely arbitrary and that Nature draws no such lines of limitation, but that each organ has numerous connections and correlations with other organs, which every specialist and practitioner as well must thoroughly comprehend.

At the time when the custom of combining the practice of diseases of the eye with that of the nose and throat was in vogue, but little was known of the accessory sinuses of the nose and their affections, and with the exception of diseases of the lachrymal apparatus, which were clearly recognized to be most often of nasal origin, it was considered that there was but little connection between diseases of the eye and those of the nose; when the separation of the specialties was made, therefore, the divorce seemed natural, and further consideration of the nose and its diseases by the ophthalmologist was deemed unnecessary, while the rhinologist, for his part, regarded the eye as an organ with lenses and strange acting muscles in which he had no interest. Within the past few years, however, an entirely new field has been opened up by a more thorough comprehension of the anatomy and pathology of the air spaces connected with the nose, and by a better appreciation of the intimate relationship which these cells have with the orbit and its contents, so that now both ophthalmologists and rhinologists realize the need of a better understanding of this border-land between their specialties. As a consequence, numerous valuable pathologic and clinical studies have been made, which have done much to elucidate the subject and to re-associate ophthalmology and rhinology, not in the practice of a single individual, it is true, but in the more natural and better combination of two, of an ophthalmologist in conjunction with a rhinologist.

Thanks to these researches, the profession is now generally conversant with the general symptomatology of diseases of the accessory sinuses, and is familiar with the most striking, at least, of the ocular symptoms. That orbital abscess is usually secondary to disease of the sinuses, that displacement of the globe may be occasioned by encroachment on the orbit by a distended sinus, that blindness may result from an involvement of the chiasm through the roof of the cavity or by an implication of the optic nerve as it passes through its foramen in the sphenoid, as a consequence of an inflammation in the cells within that bone, are facts which are generally accepted. Beyond this point, however, the knowledge of most clinicians does not extend, and it is the purpose of this paper to call attention more generally to other less striking, though perhaps more frequent symptoms, to explain their significance, and by perfecting their symptomatology, to facilitate the diagnosis in a class which in their early stages yield readily to treatment, and are easily curable, whereas, if their nature is overlooked and the pathologic process causing them is permitted to continue, conditions may arise which may not only occasion serious inconveniences and distress in the nose, and greatly interfere with the organ of sight, but my involving the brain, may actually result in the death of the patient.

Before proceeding further, it seems desirable to make several statements in regard to diseases of the accessory sinuses of the nose, of which, it is believed, most practitioners are not cognizant. The first of these is, that very pronounced disease of any, or, indeed, of all the sinuses, may occur without occasioning any subjective nasal symptoms, and, secondly, that repeated rhinologic examinations may fail to discover pus in the nares in sinusitis, the affection of the cavity being only detected by catheterization and irrigation.

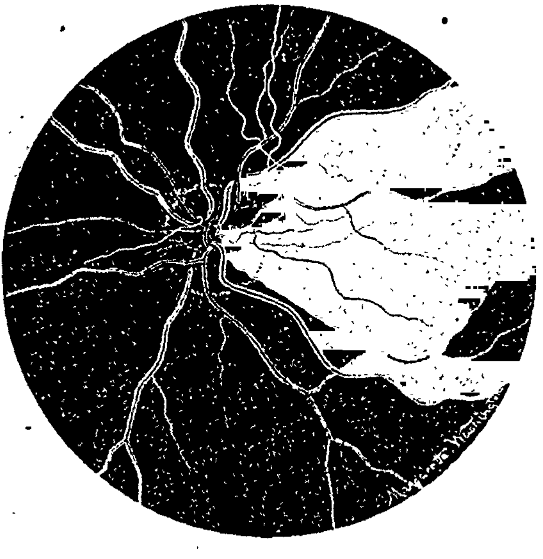
The earliest symptoms of many diseases of the accessory sinuses are ocular, and on this account the oculist is often the first to be consulted. I have no hesitation in saying that in such event, most of these symptoms are attributed to eye strain, and refraction advised. By good fortune, however, this error in diagnosis does not always work injury to the patient, for the refraction test often not only entirely relieves the symptoms, but actually cures the sublying condition, not, however, as was intended by the relief afforded the eyestrain by correcting lenses, but by the atropin which was employed to put the ciliary muscle at rest drying up the secretion in the sinuses. In many cases such desirable results do not follow, and the patient is subjected to a repeated series of examinations which fail to accomplish their purpose and permit the development of chronic conditions in the nose and sinuses, which become intractable to treatment and prolong the duration of the case indefinitely. It behooves us, therefore, as ophthalmologists, to be familiar with the symptomatology of sinus affections and to be able to detect the earliest ocular symptoms which they induce, for by so doing we may not only be of service to the rhinologist in diagnosing cases which are often obscure by reason of subjective and objective nasal signs, but also save our patients from the injury of misapplied treatment.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

SYMPTOMATOLOGY.

1. *Disturbances in Vision and the Visual Field.*—By reason of the intimate association of the optic nerve with the sphenoid bone, and as Onodi has shown, in many cases with the posterior cells of the ethmoid, this nerve is more or less implicated in the majority of active inflammatory conditions of these cavities. Indeed, were it not for the double layer of periosteum which covers the bone forming the barrier between the nerve and the sinus, and for the protection afforded by its sheath, it would be difficult to comprehend how this nerve could escape implication in any affection of the sinus, for the separating layer of bone is frequently as thin as paper and contains many dehiscences.



The involvement of the optic nerve, as a consequence of ethmoidal or sphenoidal sinusitis, may vary in degree from a simple edema to an active retrobulbar inflammation. While this latter inflammation is rare, even in cases of marked sinusitis, edematous infiltration is common, although as the change wrought in the nerve is but slight, and the symptoms which it excites are not striking, they must be searched for with some care. As a rule, the patient complains of some dimness of vision in one eye, at times of vertigo, headache and other head symptoms. When the ophthalmoscope is employed, the unaffected eye is usually found to be normal, while in the fellow eye a slight veiling of the edges of the nerve is seen, with a dilatation of the retinal veins and a choking of the lymphatics around the central vessels; in fine, the changes depicted in the sketch, which was made for me from the eye of a patient with acute sphenoiditis.[1] If the sinusitis is unchecked and retention of the contents of the cavity occurs, the nerve becomes more involved and the familiar signs of a retro-bulbar inflammation of the nerve appear.

In cases of even slight involvement of the optic nerve, the patient is usually conscious of a dimness in the affected eye, although if the vision be tested in the ordinary manner it will be found to be equally good in each eye; in other words, that the vision for form is normal. If the light on the chart be reduced, however, or if Bjerrum's test card is employed, the difference in vision between the two eyes will be at once manifest, and it will be ascertained that the dimness in the affected eye was occasioned by a diminution in the light sense, as a consequence of the edematous infiltration of the highly organized bundle of fibers which supply the macular region.

The extent of the involvement of the nerve may be further studied by the perimeter, by means of which it will often be possible to differentiate relative central and paracentral scotoma, and at times a concentric contraction of the field. If the congestion of the nerve progresses to inflammation and the conducting power of its fibers is further interfered with, then more positive defects in the visual field will appear, and it will be possible to outline absolute scotoma, both central and paracentral, and peripheral contractions in the field, in accordance with the location and the degree of involvement of the nerve. Ziem found contraction of the visual field in a large proportion of cases, especially in empyema of the antrum, and explained it by the cyclitis which he found in such cases resulting from disturbances of the circulation between the nose and the eye. Kuhnt likewise discovered concentric contraction of the field, especially for red and green. As these observations have not yet been corroborated by others, it is probable that the changes in the fields in many of the cases reported by these authors was due to neurasthenia, which may have been induced by the sinus disease.

In this connection, it should not be forgotten that optic neuritis may arise in individuals with sinusitis from other intercurrent causes, such as the abuse of tobacco or alcohol. A chief characteristic of neuritis due solely to sinus inflammation, however, is its unilateral character, for although both nerves may be affected in the optic canal by inflammation of both sphenoidal sinuses, such cases are very rare.

Tumors of the sphenoidal and ethmoid, unless they break through the walls of the sinus and involve the tissue of the nerve directly, do not, as a rule, cause disturbances of vision. As proof of this assertion, may be mentioned the cases of Baratoux, Hajek, Foucher and others, in which large sequestra of the sphenoid were exfoliated and passed through the nose, without giving rise to any defect in vision. In the cases, however, in which vision is affected by such neoplasms, Bull's statement may be accepted as authoritative, that "if an orbital tumor rapidly causes blindness and the latter starts from the temporal side of the field and leaves the region of the macula lutea unaffected to the last, and if at the same time a growth appears in the nose, it is probable that the tumor began in the sphenoidal antrum."

In addition to the various forms of implication of the optic nerve which have just been mentioned, vision may also be impaired by the mechanical obstacle offered to the proper passage of rays of light into the eye, either by reason of swollen lids, or of mucus retained in the conjunctival cul-de-sac as a consequence of lachrymal obstruction. Haze of the vitreous from uveitis may also disturb it, and, finally, imperfect focusing of the eyes, the result of interference with the function of one or more of the extraocular muscles may occasion diplopia. While there is evidence that in a very few cases of nasal and sinus disease vision may be affected, and may, for a time, be absolutely suspended, purely by reflex irritation, without anatomic cause, the clinician should be slow to attribute the blindness in such cases to a reflex, and should first carefully exclude hysteria and the possibility of the existence of retrobulbar involvement of the nerve without ophthalmoscopic signs.

---

[1] Paper read before the Baltimore Ophthalmological Society; Journal of Eye, Ear and Throat Diseases, March-April, 1905.

2. *Changes in the Orbit.*—It is now generally recognized that inflammation of the orbit of endogenic metastatic origin is rare, and that most diseases of this cavity are ectogenic, being occasioned by an inflammation of one or more of the accessory sinuses of the nose. The character of the symptoms and the form of inflammation which the disease of the sinus excites in the orbit, depends first on the particular sinus or group of sinuses affected, and secondly on the nature of the inflammation in the sinus. Thus, for example, a chronic distention of the walls of a sinus (hydrops) may occasion dislocation of the globe, with the necessary attendant of more or less functional derangement of the ocular muscles, giving rise to asthenopia or actual diplopia; or the refraction of the eye may be altered by pressure, causing changes in the axis and amount of astigmatism. and, finally, disturbance in the proper canalization of tears may result from a displacement of the puncta lachrymalia, or by a lesion in Horner's muscle in the lid. In chronic cases, vision is but rarely affected, for even when there is exophthalmus, the sigmoid flexure in the optic nerve permits it to elongate and escape injury from the traction to which the displacement of the globe subjects it; in acute inflammatory processes of the orbit, on the other hand, vision is apt to be more or less involved, either from the very pronounced displacement of the globe which occurs in this class of cases, or from a direct implication of the nerve itself in the inflammatory process.

One of the earliest signs of involvement of the orbit is a change in the contour of the orbital ring. Usually this is occasioned by a distinct projection into the orbit cells, but at times the rim may be simply raised and roughened, either wholly or in part, by periostitis. In some cases of sinusitis an acute cellulitis of the orbit may develop without premonitory signs, and lead to the formation of an abscess which may point and discharge itself either externally through the skin of the lid, or in rarer cases into the antrum, nose or tear sac. In other cases, the sinusitis causes a circumscribed swelling to appear in various parts of the orbit, which may be either as hard and unyielding as bone, or may convey to the finger the impression of containing fluid.

Although it is frequently impossible by means of the ocular symptoms alone. to make a differential diagnosis of the particular sinus involved, in many cases the character of the displacement of the eyeball is of significance. Thus, disease of the frontal sinus, which is the most frequent form of sinusitis to occasion dislocation of the globe, by reason of the extreme thinness of the bone which separates its cavity from the orbit, causes the eyeball to be displaced down and out. Mucoceles formed from the ethmoid cells are circumscribed, and do not as a rule, occasion any considerable diminution in the size of the orbital cavity; when displacement of the globe does occur, however, it is usually up and out. Dislocation from a mucocele of the sphenoid cells is uncommon, as in the rare cases in which mucoceles develop in these sinuses, the anterior wall, being the thinnest. is the first to give way and the orbital cavity escapes compression. The orbit enjoys a similar immunity in hydrops of the antrum, for the inner wall of these cells is the thinnest and is the first to yield, and the nasal cavity is encroached on. Proptosis always indicates pressure from behind the globe.

The location of the pointing of the abscess may also be of value, as indicating the particular sinus which is affected, abscesses of the frontal sinus tending to perforate at the middle of the upper lid, or at the superior internal angle of the orbit, those due to ethmoiditis at its lower, inner angle. A general orbital cellulitis may be occasioned by an acute perforation of any sinus. Disease of the frontal sinus may frequently be diagnosed by redness and swelling of the skin over the sinus, and by the pain which may be elicited by pressing on the roof of the orbit in the neighborhood of the pulley of the superior oblique muscle; indeed, it is often possible to outline the area of the sinus by noting the extent of the tenderness.

Disease of the sphenoid, as a rule, manifests itself by an early involvement of the optic nerve, either by perineuritis or by pressure on the fibers of the nerve, as it passes through the optic foramen, or along the outer wall of the sinus itself. In affections of this sinus, involvement of the ocular muscles is not uncommon, and cranial symptoms of more or less severity may arise, by reason of the connection which the sphenoid has with the floor of the middle cranial fossa. These latter symptoms may also be occasioned by perforation of the posterior wall of the frontal sinus, though this accident is of rare occurrence.

Ethmoidal disease chiefly manifests itself in the intraocular and conjunctival circulatory disturbances and in the production of asthenopia by interference with the extraocular muscles.

Inflammation of the antrum of Highmore is attended by orbital symptoms less often than that of the other cavities, but it may give rise to osteo-periostitis of the roof of the cavity and cause upward dislocation of the globe, and retrobulbar optic neuritis may result from infection through the lymphatics.

While this special symptomatology may hold good in many cases, it often fails, on account of the frequent variations in the anatomy of sinuses, for, as shown by Holmes, Cryer, Onodi, Turner and others, the relationship which the sinuses bear to one another and to the orbit is not by any means constant, and, while in most cases the cavities are separate, they may communicate. Thus, Onodi has demonstrated, by means of frozen sections, that the posterior ethmoidal cells frequently aid in the formation of the optic canal, and has noted that when this anatomic relationship is present, the layer which separates the sinus from the nerve is as thin as paper and is often perforated with dehiscences. It has been found, also, not rarely, that the frontal sinus forms the inner wall of the orbit, and that abscesses of its cavity may point in the neighborhood of the lachrymal sac.

As points of practical interest in connection with the diagnosis and treatment of orbital abscess, it should be remembered that the degree of the exophthalmus often varies in sinusitis, and that it may at times disappear entirely, being dependent on the patulency of the orifices of the sinus, the amount of protrusion of the eye being naturally more marked when the size of the cavity is increased by retained secretion. This tendency for the degree of the exophthalmus to vary should be recognized, and should not lead to its being confused with the rare cases of intermittent exophthalmus which are dependent on a dilatation of the veins of the orbit. Finally, it may be remarked that even slight transient acute sinus affections may cause actual suppuration in either the periosteal or fatty tissues of the orbit; and that infection of the orbit may occur without an actual perforation of its walls, this being true not only of the very thin walls of the ethmoid cells, but also of the much thicker ones of the frontal sinus, the infection, in such cases, being carried not by way of the necrosed bone, but through the diploe, or along any one of the fine emissaries, either vascular, lymphatic or nervous.

3. Affections of the Lachrymal Apparatus.—Sinusitis may indirectly, by way of the nasal mucous membrane, be a frequent cause of disease of the lachrymal apparatus, but is the direct agent only in those rare cases where an empyema of one of the sinuses discharges itself into the sac, or, what happens more frequently, into the neighborhood of the sac, giving rise to phlegmonous inflammation of the tissues around the sac.

These prelachrymal abscesses may result from an empyema of the frontal sinus, as a consequence of an anomalous distribution of the cells, or, finally, from an abscess of the deeper parts of the orbit, the purulent matter gravitating into the region of the sac by the peculiarity of the insertion of the fascia. The differential diagnosis between these cases and true instances of lachrymal disease is often difficult, this being especially true of the class of cases described by Peters,[2] in which there are all the signs of abscess, and the sac itself appears dilated, but where the Bowman incision and the passage of probes into the nose does not release the pus, the purulent matter escaping only after the probe is withdrawn and passed horizontally into the cells forming the inner orbital wall. Peters points out that there is actually an ectasia of the sac in these cases, which is occasioned by a stoppage of the orifices of the sac by the pressure exerted externally by pus, which comes either from an empyema of the frontal or ethmoidal cells, from the maxillary antrum, or from a maxillary periostosis excited by a carious tooth.

4. Affections of the Lids.—Edema of the lids is one of the most significant symptoms of disease of the accessory sinuses, and may often be the means of calling attention to the existence of an inflammation in these cavities, the extreme thinness of the skin of the lids, and its loose attachment to the sublying parts, causing even a comparatively slight sinusitis to give rise to this condition. The puffiness is usually most marked in the upper lid and particularly on the nasal side, though the entire lid may be swollen. This edema is to be distinguished from the inflammatory swelling and thickness of the lid which results from cellulitis, as it is entirely non-inflammatory in origin, as well as in appearance, and also from the ptosis which is at times present as a result of a palsy of the levator of the lid. The swelling is usually most marked in the mornings and disappears during the day, but it is also apt to be brought on by bending the head forward. Like all other ocular symptoms of sinusitis, the edema may disappear for a time, with the discharge of secretion from the sinus, but reappears when the fluid reaccumulates and the congestion of the mucous membrane becomes greater.

A persistent blepharitis is not uncommon in association with the chronic inflammation of the conjunctiva which sinusitis sometimes excites, and yields to treatment only after the cause has been removed.

5. Affections of the Extraocular Muscles.—By reason of the juxtaposition of some of the eye muscles with the walls of the orbit, and the very close association of the nerves which supply them with the sphenoid cavity, as they pass along the outer wall of this sinus, paresis, and even paralysis of one or more of the eye muscles, may occur as a consequence of sinusitis. While complete paralysis demands an inflammatory process of considerable intensity, and is usually occasioned by a cellulitis of the apex of the orbit secondary to either an active sphenoiditis or ethmoiditis, or more rarely to antral disease, paretic conditions of the muscles may complicate comparatively mild cases of sinusitis, and may occur when the rhinological examination reveals only a congestion of the mucous membrane lining the cavity.

Chronic empyematous conditions of the sinuses rarely occasion marked muscular insufficiencies unless signs of active inflammation arise, for the distention of the walls of the sinus under such conditions is gradual and the displacement of the globe which follows is so slow that the muscles have an opportunity to adjust themselves to the changed conditions of the visual axes under which they are forced to operate. In acute cases, the paresis is occasioned either by direct inflammatory infiltration of the long, broad, flat belly of the muscles themselves, as they lie in association with the walls of the sinus, or by an involvement of the nerves supplying them as they enter the orbit. As in many of these cases the function of the muscle is but slightly interfered with, diplopia is but rarely complained of, and can be detected only by careful search in the periphery of the field by the aid of a colored glass. Under such circumstances, the diagnosis may often be facilitated by requesting the patient to indicate in which direction movement of the eyes is especially painful, as considerable distress is often excited when the eyes are rotated into the position in which fullest demand is made on the affected muscle.

As a consequence of this paretic condition of the muscles, vision is often blurred, and while, as just stated, many of the palsies are not sufficiently marked to induce diplopia, when the eyes make their ordinary excursions, the imbalance created is sufficient to confuse vision, to cause vertigo, to excite reflex gastric symptoms and to render the near use of the eyes difficult. By reason of their anatomic relationships, paralysis of the levator, of the superior rectus and superior oblique muscles, serves to indicate a probable involvement of the frontal cells; paralysis of the internal rectus, an involvement of the ethmoidal; and paralysis of the inferior rectus or inferior oblique muscles, an inflammation of the antral cells. As sphenoiditis may, however, implicate any or all of the nerves supplying these muscles, the value of differentiating the precise muscle affected, as a localizing symptom indicating the involvement of any particular sinus, is not great. Diplopia in the periphery of the field does not always indicate that a muscle has been paralyzed, for it may be induced by a slight displacement of the globe, either by exudation or by the distended wall of a sinus.

Ptosis from paralysis must not be mistaken for dropping of the lid from edema. This differentiation is not always easy, for, as in all other signs and symptoms of sinusitis, both the edema and the palsy may be transient and may disappear, only to reappear after several hours or days, or even much longer intervals. It is by reason of this transient character that palsies of extraocular muscles due to sinusitis have been confused with the palsies which occur in connection with the rare affection known as "migraine ophthalmoplegic," or recurrent oculomotor palsy. In this condition, paralysis of one or more of the eye muscles supplied by the third nerve—though muscles supplied by other nerves may be affected—occurs in connection with an attack of migraine. The attacks come on in periodical crises and recur at irregular intervals. I recently had under my care a case of transient palsy of a part of the right third nerve, which appeared in association with great pain in the eye and temple, and the occurrence of a spectrum, where the symptoms were undoubtedly induced by an acute inflammation of the ethmoidal and sphenoidal cells. Although a careful analysis of a majority of the recorded cases of migraine ophthalmoplegic indicates a probable sinus origin in the number, I do not believe that such cases are true instances of this rare form of disease, as I consider that, while the pathology of the affection is in doubt, the strongest evidence points to its being of central origin.

---

[2] Zeitschrift für Augenheilkunde, 1892, ii, 2.

I am of the opinion that if many of the cases of palsy of extraocular muscles attributed to rheumatism were analyzed that an affection of a sinus would be found to be the underlying cause in many instances. Such palsies may appear after "catching cold," and are associated with more or less pain on moving the eye, and possess other characteristics which suggest the presence of an acute sinusitis.

6. *Affections of the Conjunctiva.*—In chronic disease of the sinuses, the mucous membrane of the nose is not infrequently affected, and the thickening and congestion which exist there are often transmitted to the mucous membrane which lines the lids and covers the eyeball, not only by direct continuity of structure, by way of the tear passages, but also as a consequence of the general venous and lymphatic congestion of all the parts about the eye, occasioned by the disease of the sinus. In acute cases the conjunctiva is not rarely inflamed, probably by direct infection from the mucous membrane lining the sinuses, and presents the appearance of a typical attack of catarrhal conjunctivitis. In many of the chronic cases, the follicles of the conjunctiva become enlarged, and it is the involvement of these bodies, together with the turgescence of the conjunctiva, which occasions the feeling of heaviness of the lids and aggravates the asthenopia which is so frequent a symptom of sinus disease.

7. *Affections of the Cornea.*—Disease of the accessory sinuses rarely gives rise to keratitis except indirectly, as a consequence of the exposure to which the cornea is at times subjected in extreme degrees of displacement of the globe by a distention of the walls from empyema or by cellulitis, or as a part of a panophthalmitis which may be excited by the cellulitis. Occasionally, however, herpetic-like blisters may form on the cornea, as in cases recently reported by Ellinger[3] and myself,[4] as a consequence of implication of the fifth nerve as it passes along the outer wall of the sphenoid sinus.

8. *Pupillary Changes.*—A slightly dilated pupil may at times direct the attention of the clinician to the existence of an inflammation in the posterior ethmoidal or sphenoidal sinuses, being occasioned by the optic neuritis and the consequent diminution in vision and the reduction in the light sense which accompanies the inflammation of the nerve. This dilatation increases disproportionately when the illumination is diminished and is unattended by any restriction in the play of the iris to direct or indirect light stimulus. In cases of active inflammation at the back of the orbit, the pupil may be widely dilated and fixed, from serious involvement of the third nerve.

9. *Affections of the Uveal Tract.*—When the enormous extent of mucous membrane which is spread over the nose and its sinuses is taken into consideration, and account made of its large venous and lymphatic channels and the very close and intimate association which these vessels have with the blood vessels and lymphatics of the eye, it seems extraordinary that the eye should not be the seat of active inflammatory processes in all cases of sinusitis, and that the uveal tract, especially, should not be frequently involved. And yet it would appear, despite the claims of Zeim and others, that involvement of the interior of the eyeball, either by emboli or direct infection, is very rare. The thought occurs that, in order to obviate this, there is some controlling mechanism, some peculiar arrangement, perhaps, of the vessels, of which we are as yet unaware, which protects the eye from participating in these inflammatory conditions, just as there is some subtle mechanism which controls and regulates the intraocular circulation and makes it more or less independent of that of the general system.

Zeim, Fromaget, Fish and others have recorded a number of cases of uveitis due to sinusitis, and attribute the inflammation to the general impediment in the circulation and to the irritation of the maxillary branch of the fifth nerve, occasioned by the empyema of the sinus. These authors claim to have seen marked improvement in cases of this nature follow treatment of the sinus. As yet, however, cases of uveitis from sinusitis have been recorded by but a few, and further observations are necessary before the correctness of these views can be established.

10. *Cataracts.*—Equally problematical is the claim of Zeim that cataracts may be occasioned by disease of the sinuses. This author asserts that he found chronic suppuration in the nose in many cases of opacity of the lens, and adds that in a number of cases of unripe cataract he improved vision by treating the sinuses. Kuhnt partially supports this statement, as he states that he frequently saw spoke-like opacities of the posterior cortical in antral disease, especially in young individuals, with no other changes visible in the fundus or general system. The same author has seen vitreous opacities clear up after treatment of the sinuses. He attributed both the change in the lens and vitreous to an interference with the nutrition of the ciliary body, which he considered to be of a circulatory nature. An observation of Eversbusch which is especially interesting may be cited in this connection, of a swelling of the middle turbinated body preceding a so-called sympathetic inflammation of the other eye. As a consequence of this experience, he makes it a rule to examine the nose in cases where there is any ground to suspect sympathetic trouble, enucleation of the affected eye being advised as soon as nasal symptoms arise.

[4] Journal of Eye, Ear and Throat Diseases, March-April, 1905.

not able to see an electric light before the eye, but after opening the sphenoid his sight was completely restored.

Dr. E. J. Brown, Minneapolis, fifteen years ago reported the case of a boy about ten years of age who had suffered from diminution of vision and very contracted fields. The boy had very large adenoids and Dr. Brown ascribed the trouble largely to that. On removal of the adenoids the fields were immediately restored to normal. The patient remained under observation for many years and is still under his care. Dr. Brown found later that the boy had sphenoid disease and the optic atrophy which resulted from that condition has persisted. Dr. Brown had a patient who came to him complaining of slight tenderness at the inner canthus, over the root of the nose and having a slight amount of astigmatism to which his trouble was at first ascribed. Correction of that, however, gave no relief. He came back, and on entering a small probe into the frontal sinus Dr. Brown caused the exudation of a small amount of pus. Removal of the head of the middle turbinate on that side gave relief to all his symptoms. Another case of similar character was relieved in that way within a few weeks.

Dr. W. H. Snyder, Toledo, called attention to the fact that a number of prepared sections show perfectly the relation of the mucous membrane after the bone has been removed and there seems to be no normal shape and size of the sinuses. In a number he prepared last spring there was no opening into the sinus. Simple probing through the nasal cavity would not bring pus in such cases.

Dr. F. W. Hilscher, Spokane, declared that he has seen a great many patients in whom symptoms of this character have been going on for a great while with more or less destruction of vision and that have been through the hands of men otherwise competent. He has had cases in which he did not discover pus at all in the sinuses but in which there was pressure between the turbinates and septum that gave rise to the same symptoms. He thinks, therefore, that we need not always expect to find pus to account for these symptoms. Just contact of the surfaces will produce them. He mentioned the case of a middle aged lady with a hypermetropic error who declared that whenever she took the glasses off she had a great deal of tinnitus.

Dr. S. D. Risley, Philadelphia, said that his attention once having been called to the important relation between certain obscure affections of the eye and the diseases of the sinuses contiguous to the orbit he was surprised to find how frequently they occur and rather reproached himself for not having observed the fact before. This condition need not cause surprise, however, when it is remembered that these sinuses all drain into the nasal cavities and the numerous circumstances in life which lead to the blocking up of the ducts and the close anatomic relationship which exists between the sinuses and the orbit are taken into consideration. Dr. Risley was struck with the statement with regard to the absence of choroidal disease in the cases observed by Dr. Posey. Dr. Risley published a group of cases some time ago in which defective vision was associated with disease of the sinuses and in all there was marked choroidal disease. He thinks, therefore, from personal observation, that choroidal disease should not be excluded as one of the associations with this form of trouble. He recently had a patient with exophthalmus, and optic neuritis of obscure origin, in whom it was only after probing the frontal sinus on that side that the diagnosis was cleared up. On opening this Dr. Risley found a large collection of pus which had escaped into the orbit and collected back of the eyeball. In another case of exophthalmus, transillumination showed the trouble to be in the maxillary antrum on that side. These conditions are varied and, therefore, in obscure cases of eye disease the study of the case should never be considered complete until we have observed, by transillumination and other means open to investigation, the condition of the accessory sinuses.

Dr. Leartus Connor, Detroit, said that it has been a habit of his for many years when any case of eye trouble was not satisfactorily disposed of within a reasonable time to investigate the sinuses. He has sometimes been reproached by his colleagues for calling attention to these matters. The expert management of these conditions in their gravest form calls for manipulation that not all ophthalmologists desire to enter into.

Dr. Edward Jackson, Denver, declared that one point of Dr. Posey's paper needs to be reiterated, and that is the allusion to the difficulty of recognizing sinus disease. Dr. Jackson has so frequently referred patients when he felt that sinus disease was the cause of the eye trouble, to expert rhinologists and had them come back with the report that there was nothing the matter. He now feels more confidence in a certain clinical association of symptoms than in the ordinary rhinologic examination and in some cases certainly the examination must go as far as the removal of considerable tissue and very careful examination before a negative reply can be accepted. A few months ago Dr. Patterson, of Colorado Springs, published a paper on the connection of sinus disease with vitreous opacities. Dr. Jackson is inclined to think this a rather common cause of uveal trouble; sometimes producing vitreous opacities and sometimes not.

Dr. J. A. Donovan, Butte, Mont., said that those who have watched adenoid children must have noticed the effect of that trouble on vision, especially on accommodative power. A diagnosis in these cases is a very important matter and he is convinced that often the symptoms are due to pressure and are much the same as those of ordinary rhinitis. The history is often the same as in rhinitis. It is almost impossible to make a diagnosis in these cases at one examination and it is not absolutely necessary, for the first treatment is not directed to the sinuses. Relieving the pressure of the anterior end of the middle turbinate often relieves the patients at least for some time.

Dr. J. A. L. Bradfield, La Crosse, Wis., said that four months ago a woman, aged 32, was referred to him as a case of glaucoma. The fields for color were contracted. Vision was 20/100 and there was history of right hemicrania. Examination of the nose showed the middle turbinate to be large and cystic and on its removal recovery was rapid. Within a week vision was almost normal.

Dr. H. Stillson, Seattle, Wash., stated that last year he published a paper on the relation between diseases of the nose and diseases of the eye. In that paper he reviewed the literature on the subject and published statistics from his own practice. The subject is a very old one, there having existed considerable literature fifty years ago, but it is a subject that has been forgotten until recently and it is only just now that the extreme importance and the extreme frequency of the diseases of the eye and brain in their relation to diseases of the nose has been realized. Ideas of the symptomatology of the diseases of the accessory cavities of the nose are still extremely hazy.

Dr. William C. Posey said, in reply to Dr. Bradfield, that the diminution in vision in the case he cited might have been due to edematous infiltration of the optic nerve. Sometimes if the vision be tested in cases of this kind it will be found to be normal, but on lowering the light the vision will be found to fall much lower than would be the case in the fellow eye, showing an interference in the conducting power of the fibers of the optic nerve. Dr. Posey agreed with Dr. Jackson that the great difficulty is in diagnosis in these cases. It is true that it is not necessary to find pus to account for these symptoms; simple congestion of the sinuses may produce them.

Malaria in British Central Africa.—Dr. H. Hearsey, principal medical officer British Central Africa, states, in the *Journal of Tropical Medicine*, that there are two forms of malarial fever in that country—the tertiary and the æstivo-autumnal. The tertian variety is by far the more common, and it frequently takes the type of a double infection. Multiple infection by tertian parasites is met with, causing the so-called irregular fever, and is the only variety of the fever which is generally resistant to quinin. Dr. Hearsey is inclined to regard hemoglobinuric fever as a "pernicious" form of the æstivo-autumnal, the absence of the parasites in the peripheral circulation being probably due to their having left the peripheral circulation for the spleen and bone marrow.

11. Refraction.—Diseases of the sinus may occasion change in the refraction directly by the pressure exerted on the globe by the wall of a dilated sinus, and it is not unlikely that in early childhood disease of the nose may indirectly alter the refractive condition. Thus, it is well known that the form of the orbit determines, in large measure, the shape of the human eyeball. As a further step, Zeim has proved by experiments on dogs and rabbits that blockage and purulent inflammation of a nares will occasion marked inflammation in the skull and side of the face, and Kuhnt has deduced that the same facial asymmetry may result in human subjects from a deviation of the septum which is consecutive to a chronic swelling of the nasal mucous membrane. Batten and Fish consider sinusitis to be an etiological factor in myopia, as a consequence of congestion and spasm of the ciliary muscle, thereby retarding its natural contraction and relaxation and reducing accommodation.

12. Asthenopia.—Asthenopia is not rare in sinusitis, and the failure of proper lenses to relieve such symptoms is explained by the fact that they originated, not in an error of refraction, but in an inflammation of a sinus. In many of the cases the asthenopia may be attributed to the conjunctivitis which sinusitis excites, but in others it is traceable to an interference with the ciliary muscle, and actual testing will show a diminution in the range of accommodation. Hoople, who has contributed an interesting article on this subject, thinks that a moderate amount of pressure or mechanical irritation of the middle turbinate and adjacent septum will temporarily impair the function not only of the ciliary muscle, but, to a more or less variable extent, that of the internal rectus muscle as well, thereby aggravating the asthenopic symptoms still more. De Schweinitz, also, has called attention to asthenopia as a consequence of intranasal disease, and thought these cases particularly interesting, because in each instance the refraction error and the faulty muscle balance were of such a character that the symptoms of which the patients complained would naturally be ascribed to these anomalies, and because the patients were, to a great extent, unaware of, or at least indifferent to, any serious or decided lesions in the naso-pharyngeal region. In an analysis of a large number of cases of asthenopia, Gradle found chronic catarrhal rhinitis, with secondary hypertrophy, or with stenosis due to deviations of or excrescences on the septum, in about 3 per cent.

13. Headache and Neuralgia.—Headache and neuralgia are rather constant symptoms of sinusitis, and, though they frequently possess no features which serve to differentiate them from similar pain due to other causes, at other times they present characteristics which are significant of sinusitis, and it is very essential that ophthalmologists should be conversant with these qualities, since the laity, who are ignorant as yet that headaches may have a nasal origin, and impute all forms of head pain to eyestrain, seek them first for relief.

The headaches of sinusitis occur usually in the morning and are characterized by continuous pain with severe exacerbations, which radiate around the orbit and within the zone of distribution of the fifth nerve; or they may take the form of a general head pain, of a facial neuralgia, or of a toothache, and may be constant or recur in severe paroxysms. Injection of the conjunctiva, lachrymation and photophobia are often present. The location of the pain is significant, for, while it may be reflected to a part of the head remote from the affected sinus, and may even be felt in the opposite side, yet its localization is generally characteristic and may enable the clinician to differentiate the particular sinus affected. Thus, neuralgia of the supraorbital nerve is very significant of frontal disease, and dental neuralgia will frequently indicate the existence of antral disease. Frontal headache is suggestive of ethmoidal and frontal disease, while occipital pain is usually caused by sphenoiditis, though disease of the frontal sinus may evidence itself in pain in that locality also. Pain in the vertex and at the back of the eyes is usually caused by sphenoiditis, though, on account of the close proximity of the fifth nerve to the lateral wall of the sinus and the nearness of the sphenopalatine ganglia, reflex pain to any part of the head may be occasioned by disease of that cavity. A distressing pain across the bridge of the nose is peculiar to ethmoid disease.

The headache of sinusitis may take the form of hemicrania, and may simulate migraine, or even the rare condition known as "migraine ophthalmoplegic." Pain is almost always present in acute affection of the sinuses and may attain great severity, while in chronic cases all suffering may be absent; in some cases, however, where secretion has been long retained and where there is a hyperostosis of the walls of the sinus as a consequence of repeated attacks of sinusitis, the suffering may be prolonged and severe. A symptom of very great value in the diagnosis of sinusitis is the sensation which is evoked by palpation of the affected areas. Thus, in frontal sinusitis exquisite pain is occasioned by palpating the forehead and the roof of the orbit at its upper, inner angle, and the same is true of the region over the antrum when that cavity is the seat of an acute inflammation.

In addition to head pain, there may be other symptoms of a general character, such as fever, evidences of cerebral irritation and congestion, neurasthenia and gastric disturbances. The increased temperature is due to absorption of pus and is generally irregular. Gastric symptoms are occasioned by swallowing some of the fetid discharge of the sinuses, and loss of appetite or a true gastritis may result. Such cerebral symptoms as malaise, inability to concentrate the mind, and actual depression, verging almost on melancholia, are observant more frequently in chronic cases. Delirium and mania betoken a state of actual involvement of the cerebral activity. When cerebral symptoms arise in sinusitis, they indicate either an involvement of the meninges without perforation of the wall of a sinus, or more usually an actual perforation, in which latter event abscess of the brain rapidly follows. Abscesses of the orbit not rarely give rise to cerebral complications, and meningitis, abscess of the brain and thrombosis of the cavernous sinus may follow.

DISCUSSION.

Dr. C. R. Holmes, Cincinnati, said that a large field is still unexplored in the relation between the accessory cavities and the eye. He has taken many fields of vision in these cases but has not found that many patients exhibited contraction. He has found that in many chronic cases there is a rise of temperature, sometimes of one or two degrees daily. He thinks this a chronic septic condition. Dr. Holmes said that in sphenoidal cases the pain is generally referred to the temple. He passed around a section from such a case, showing how easy it is for a disease in the sphenoidal cavity to invade the optic nerve and the eye. He said that this is the first case on record in which there was total blindness following trouble with the sphenoid on one side. The patient was not able to see an electric light before the eye, but after opening the sphenoid his sight was completely restored.

Dr. E. J. Brown, Minneapolis, fifteen years ago reported the case of a boy about ten years of age who had suffered from diminution of vision and very contracted fields. The boy had very large adenoids and Dr. Brown ascribed the trouble largely to that. On removal of the adenoids the fields were immediately restored to normal. The patient remained under observation for many years and is still under his care. Dr. Brown found later that the boy had sphenoid disease and the optic atrophy which resulted from that condition has persisted. Dr. Brown had a patient who came to him complaining of slight tenderness at the inner canthus, over the root of the nose and having a slight amount of astigmatism to which his trouble was at first ascribed. Correction of that, however, gave no relief. He came back, and on entering a small probe into the frontal sinus Dr. Brown caused the exudation of a small amount of pus. Removal of the head of the middle turbinate on that side gave relief to all his symptoms. Another case of similar character was relieved in that way within a few weeks.

Dr. W. H. Snyder, Toledo, called attention to the fact that a number of prepared sections show perfectly the relation of the mucous membrane after the bone has been removed and there seems to be no normal shape and size of the sinuses. In a number he prepared last spring there was no opening into the sinus. Simple probing through the nasal cavity would not bring pus in such cases.

Dr. F. W. Hilscher, Spokane, declared that he has seen a great many patients in whom symptoms of this character have been going on for a great while with more or less destruction of vision and that have been through the hands of men otherwise competent. He has had cases in which he did not discover pus at all in the sinuses but in which there was pressure between the turbinates and septum that gave rise to the same symptoms. He thinks, therefore, that we need not always expect to find pus to account for these symptoms. Just contact of the surfaces will produce them. He mentioned the case of a middle aged lady with a hypermetropic error who declared that whenever she took the glasses off she had a great deal of tinnitus.

Dr. S. D. Risley, Philadelphia, said that his attention once having been called to the important relation between certain obscure affections of the eye and the diseases of the sinuses contiguous to the orbit he was surprised to find how frequently they occur and rather reproached himself for not having observed the fact before. This condition need not cause surprise, however, when it is remembered that these sinuses all drain into the nasal cavities and the numerous circumstances in life which lead to the blocking up of the ducts and the close anatomic relationship which exists between the sinuses and the orbit are taken into consideration. Dr. Risley was struck with the statement with regard to the absence of choroidal disease in the cases observed by Dr. Posey. Dr. Risley published a group of cases some time ago in which defective vision was associated with disease of the sinuses and in all there was marked choroidal disease. He thinks, therefore, from personal observation, that choroidal disease should not be excluded as one of the associations with this form of trouble. He recently had a patient with exophthalmus, and optic neuritis of obscure origin, in whom it was only after probing the frontal sinus on that side that the diagnosis was cleared up. On opening this Dr. Risley found a large collection of pus which had escaped into the orbit and collected back of the eyeball. In another case of exophthalmus, transillumination showed the trouble to be in the maxillary antrum on that side. These conditions are varied and, therefore, in obscure cases of eye disease the study of the case should never be considered complete until we have observed, by transillumination and other means open to investigation, the condition of the accessory sinuses.

Dr. Leartus Connor, Detroit, said that it has been a habit of his for many years when any case of eye trouble was not satisfactorily disposed of within a reasonable time to investigate the sinuses. He has sometimes been reproached by his colleagues for calling attention to these matters. The expert management of these conditions in their gravest form calls for manipulation that not all ophthalmologists desire to enter into.

Dr. Edward Jackson, Denver, declared that one point of Dr. Posey's paper needs to be reiterated, and that is the allusion to the difficulty of recognizing sinus disease. Dr. Jackson has so frequently referred patients when he felt that sinus disease was the cause of the eye trouble, to expert rhinologists and had them come back with the report that there was nothing the matter. He now feels more confidence in a certain clinical association of symptoms than in the ordinary rhinologic examination and in some cases certainly the examination must go as far as the removal of considerable tissue and very careful examination before a negative reply can be accepted. A few months ago Dr. Patterson, of Colorado Springs, published a paper on the connection of sinus disease with vitreous opacities. Dr. Jackson is inclined to think this a rather common cause of uveal trouble; sometimes producing vitreous opacities and sometimes not.

Dr. J. A. Donovan, Butte, Mont., said that those who have watched adenoid children must have noticed the effect of that trouble on vision, especially on accommodative power. A diagnosis in these cases is a very important matter and he is convinced that often the symptoms are due to pressure and are much the same as those of ordinary rhinitis. The history is often the same as in rhinitis. It is almost impossible to make a diagnosis in these cases at one examination and it is not absolutely necessary, for the first treatment is not directed to the sinuses. Relieving the pressure of the anterior end of the middle turbinate often relieves the patients at least for some time.

Dr. J. A. L. Bradfield, La Crosse, Wis., said that four months ago a woman, aged 32, was referred to him as a case of glaucoma. The fields for color were contracted. Vision was 20/100 and there was history of right hemicrania. Examination of the nose showed the middle turbinate to be large and cystic and on its removal recovery was rapid. Within a week vision was almost normal.

Dr. H. Stillson, Seattle, Wash., stated that last year he published a paper on the relation between diseases of the nose and diseases of the eye. In that paper he reviewed the literature on the subject and published statistics from his own practice. The subject is a very old one, there having existed considerable literature fifty years ago, but it is a subject that has been forgotten until recently and it is only just now that the extreme importance and the extreme frequency of the diseases of the eye and brain in their relation to diseases of the nose has been realized. Ideas of the symptomatology of the diseases of the accessory cavities of the nose are still extremely hazy.

Dr. William C. Posey said, in reply to Dr. Bradfield, that the diminution in vision in the case he cited might have been due to edematous infiltration of the optic nerve. Sometimes if the vision be tested in cases of this kind it will be found to be normal, but on lowering the light the vision will be found to fall much lower than would be the case in the fellow eye, showing an interference in the conducting power of the fibers of the optic nerve. Dr. Posey agreed with Dr. Jackson that the great difficulty is in diagnosis in these cases. It is true that it is not necessary to find pus to account for these symptoms; simple congestion of the sinuses may produce them.

Malaria in British Central Africa.—Dr. H. Hearsey, principal medical officer British Central Africa, states, in the *Journal of Tropical Medicine*, that there are two forms of malarial fever in that country—the tertiary and the æstivo-autumnal. The tertian variety is by far the more common, and it frequently takes the type of a double infection. Multiple infection by tertian parasites is met with, causing the so-called irregular fever, and is the only variety of the fever which is generally resistant to quinin. Dr. Hearsey is inclined to regard hemoglobinuric fever as a "pernicious" form of the æstivo-autumnal, the absence of the parasites in the peripheral circulation being probably due to their having left the peripheral circulation for the spleen and bone marrow.

ACID INTOXICATION, AND LATE POISONOUS EFFECTS OF ANESTHETICS.

HEPATIC TOXEMIA. ACUTE FATTY DEGENERATION OF THE LIVER FOLLOWING CHLOROFORM AND ETHER ANESTHESIA.*

ARTHUR DEAN BEVAN, M.D.
AND
HENRY BAIRD FAVILL, M.D.
CHICAGO.

(*Concluded from page 696.*)

Stocker,[5] in 1895, reports an operation for strangulation of pedicle of ovarian cyst. A gangrenous pedicle was found and cyst and pedicle were removed. Stocker makes no mention of the anesthetic, but in Cohn's article referred to later he mentions chloroform as the anesthetic used. Probably this statement was made to Cohn personally. Shortly after the operation icterus was noted, the patient became restless, finally became comatose and died. An acute yellow atrophy of the liver was found at autopsy. Stocker believes that the atrophy resulted from the absorption of toxins from the strangulated and gangrenous pedicle. He does not lay much stress on the anesthetic used.

Victor Bandler,[14] in 1896, reports a case of late chloroform poisoning from Wölfler's clinic.

Patient.—Male, 42 years old; glass blower by occupation; apparently in good health, but a heavy beer drinker, often taking as many as 101 daily, was operated on at noon, July 18, 1895, for an incarcerated inguinal hernia. Omentum was found in hernial sac and was resected. The operation lasted about one hour. Anesthesia was easily produced and about 80 grams of chloroform were used. The morning following the operation icterus was noted. On the second day the icterus had increased and bile pigment was found in the urine. Patient was quiet, no pain in abdomen or wound; tongue moist; some headache and a striking apathy. Temperature 38.2 C., pulse 92. On the third day icterus was marked; urine brownish color; some blood in stool; urine rich in bile pigment; albumin, and in the sediment yellowish, granular and hyaline casts. There was some pain in the liver region, but the liver apparently was not enlarged. During the day icterus increased and little urine was passed. During the evening the patient suddenly became delirious, attempted to get out of bed and was restless.

On the following morning the patient was unconscious: there were hemorrhages into the abdominal wall, but the wound was clean. Leucin and tyrosin were found in the urine, and a diagnosis of acute yellow atrophy was made. The patient became comatose. There were petechiæ in the skin. Terminal rise of temperature to 40 C. Death occurred four days after operation.

Anatomic Diagnosis.—Acute yellow atrophy of the liver; icterus; multiple hemorrhages; fatty degeneration of the heart; chronic Bright's disease.

Erlach,[17] in 1896, in a personal communication to Bandler,[14] reports the death of a patient from acute yellow atrophy of the liver, following the use of Billroth's mixture; total extirpation of the uterus was done for fibroids. The predisposing cause was probably gastritis and catarrhal icterus. At the autopsy acute yellow and red atrophy of the liver was found.

Marthen,[18] in 1896, reports the following clinical history:

Patient.—Woman, 34, insane. The roots of fourteen carious teeth were removed under chloroform anesthesia. Anesthesia lasted about forty minutes, and about 70 c.c. of chloroform were used. Patient vomited frequently after anesthetic. The day following operation some icterus of the face and back was noted. Vomiting continued, and on the third day the patient became restless, uttered piercing cries and attempted to leave bed. There was convulsive tic of face and upper extremities. Pupils, maximum dilatation. Cheyne-Stokes respiration. Death.

Anatomic Diagnosis.—Fatty degeneration of heart muscle and kidneys. Acute fatty degeneration of liver.

W. Mintz,[19] in 1900, reports the following case:

Patient.—Male, 40 years old, heavy drinker, always well previous to present trouble. Operation, opening of appendiceal abscess and removal of gangrenous appendix. During evening of second day patient vomited three times; the vomitus contained blood. Vomiting persisted on the third day, accompanied by singultus. Slight jaundice, which increased in intensity. Death occurred seven days after operation, eighteen days after beginning of disease.

Anatomic Findings.—Erosions in duodenum and along lesser curvature, corresponding to which were numerous obliterated *arterial lumina.*

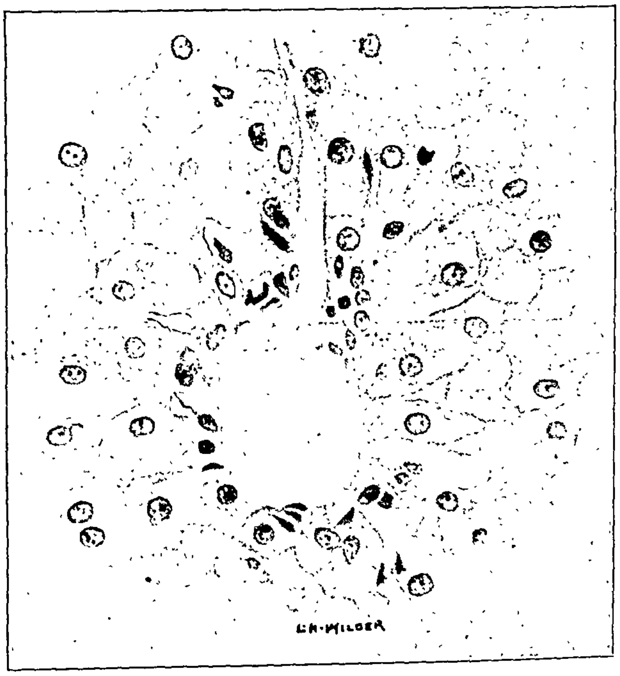

Fig. 1.—Section of liver of healthy rabbit, showing nuclear and cytoplasmic characteristics. Stained with hematoxylin and eosin.

Anesthetic is not mentioned. The author speaks of direct relation to epityphilitis.

Cohn,[4] in 1902, reports a case of protracted chloroform action resulting fatally.

Patient.—A woman, aged 21, with no apparent predisposing cause, was operated on Jan. 3, 1902, for the removal of diseased uterine adnexa. The patient took cloroform well, about 175 grams being used. During the day the patient was excited and restless, and gained complete consciousness only once. There was slight vomiting after anesthesia.

January 4: She had a sleepless night, tossed about in bed, and finally was restrained by nurse. The evening temperature, 38 C.

January 5: Patient slept a great deal, talked with nurse at times, and was conscious.

January 6: Jaundice was noted. At half-past 8 the patient suddenly became very restless and delirious. She tossed about

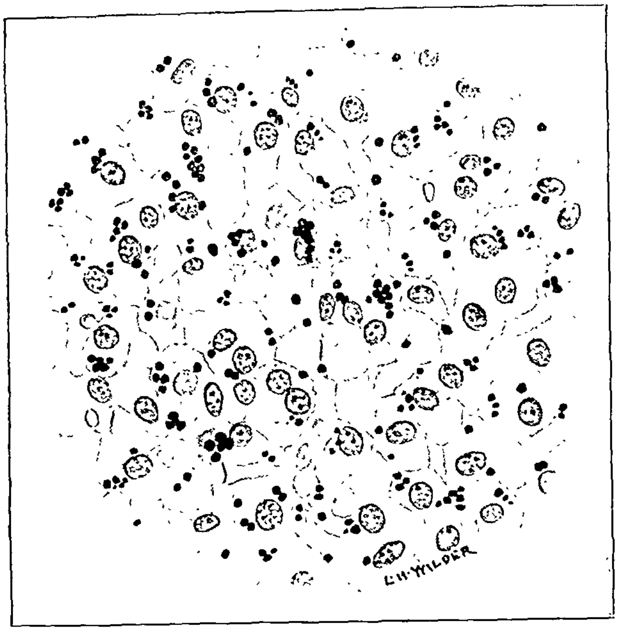

Fig. 2.—Section of liver of healthy rabbit, showing the amount and distribution of fat in the liver cells. Fat globules are represented by the heavy black. Drawing made from a frozen section, stained with Sudan III and Delafield's hematoxylin.

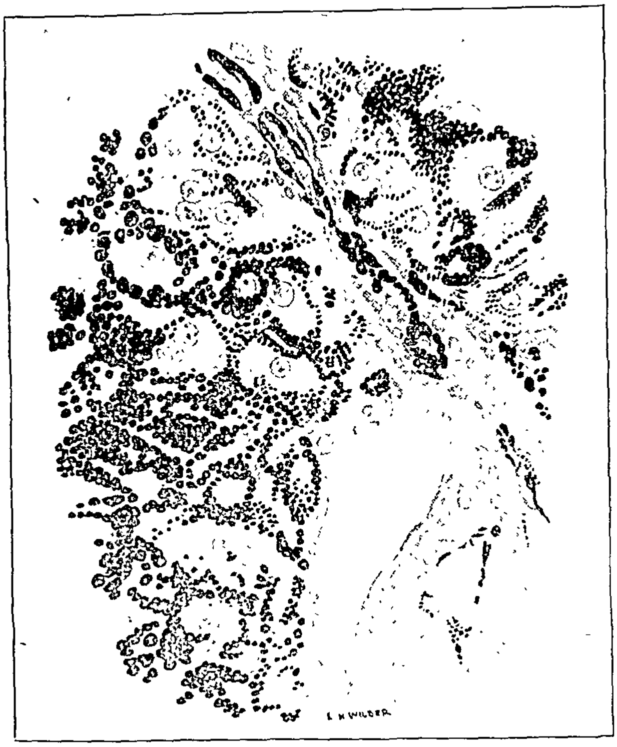

Fig. 3.—Section of liver of a rabbit, which had been chloroformed for two hours and killed forty-eight hours later. The rabbit became drowsy about twenty-four hours after the anesthetic, refused food and was partially paralyzed in the forelegs. The liver presented the typical appearance of fatty degeneration. Drawing made from a frozen section stained with Sudan III and Delafield's hematoxylin. Fat is represented by the heavy black. Fatty degeneration of the liver cells is marked; the fat droplets are grouped about the periphery of the liver cell and are separated from the nucleus by a clear, unstainable, degenerating cytoplasm. The fatty changes are found throughout the lobule, and are not confined to any particular zone.

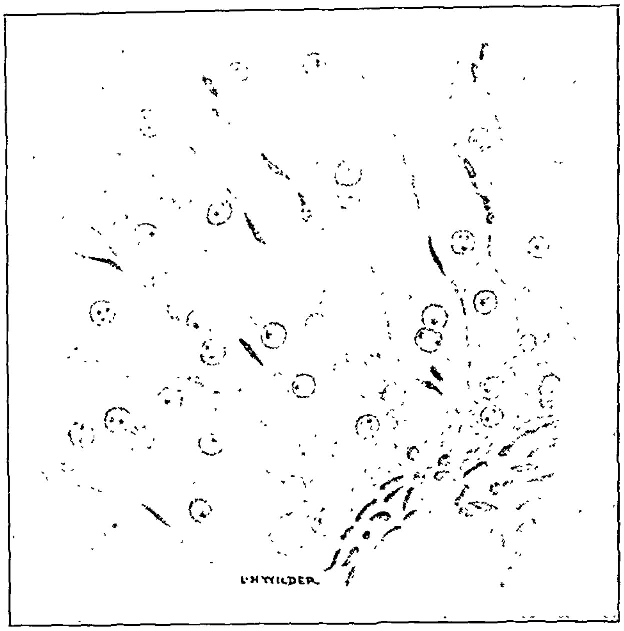

Fig. 4.—Section from liver of rabbit, which had been chloroformed for two hours and killed forty-eight hours later, stained with hematoxylin and eosin. The liver cells are swollen and vacuolated, the fat droplets having been dissolved out during the process of embedding. The nuclei stain poorly, the chromatin network having been partially destroyed. In some cells karyorrhexis is well advanced.

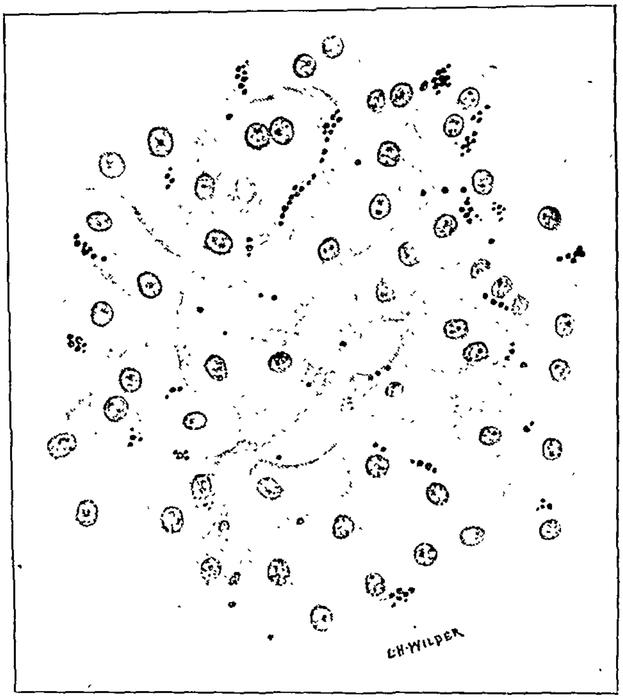

Fig. 5.—Section of liver from a rabbit, which had been etherized for two hours and killed seventy-two hours later. The animal was not sick after the anesthetic. The liver was macroscopically normal. The fat does not exceed in amount the fat found normally in the liver. It should be noted, however, that the greater part of the fat is intercellular, whereas in the normal liver it is intracellular.

ACID INTOXICATION, AND LATE POISONOUS EFFECTS OF ANESTHETICS.

HEPATIC TOXEMIA. ACUTE FATTY DEGENERATION OF THE LIVER FOLLOWING CHLOROFORM AND ETHER ANESTHESIA.*

ARTHUR DEAN BEVAN, M.D.
AND
HENRY BAIRD FAVILL, M.D.
CHICAGO.

(*Concluded from page 696.*)

Stocker,[5] in 1895, reports an operation for strangulation of pedicle of ovarian cyst. A gangrenous pedicle was found and cyst and pedicle were removed. Stocker makes no mention of the anesthetic, but in Cohn's article referred to later he mentions chloroform as the anesthetic used. Probably this statement was made to Cohn personally. Shortly after the operation icterus was noted, the patient became restless, finally became comatose and died. An acute yellow atrophy of the liver was found at autopsy. Stocker believes that the atrophy resulted from the absorption of toxins from the strangulated and gangrenous pedicle. He does not lay much stress on the anesthetic used.

Victor Bandler,[14] in 1896, reports a case of late chloroform poisoning from Wölfler's clinic.

Patient.—Male, 42 years old; glass blower by occupation; apparently in good health, but a heavy beer drinker, often taking as many as 101 daily, was operated on at noon, July 18, 1895, for an incarcerated inguinal hernia. Omentum was found in hernial sac and was resected. The operation lasted about one hour. Anesthesia was easily produced and about 80 grams of chloroform were used. The morning following the operation icterus was noted. On the second day the icterus had increased and bile pigment was found in the urine. Patient was quiet, no pain in abdomen or wound; tongue moist; some headache and a striking apathy. Temperature 38.2 C., pulse 92. On the third day icterus was marked; urine brownish color; some blood in stool; urine rich in bile pigment; albumin, and in the sediment yellowish, granular and hyaline casts. There was some pain in the liver region, but the liver apparently was not enlarged. During the day icterus increased and little urine was passed. During the evening the patient suddenly became delirious, attempted to get out of bed and was restless.

On the following morning the patient was unconscious: there were hemorrhages into the abdominal wall, but the wound was clean. Leucin and tyrosin were found in the urine, and a diagnosis of acute yellow atrophy was made. The patient became comatose. There were petechiæ in the skin. Terminal rise of temperature to 40 C. Death occurred four days after operation.

Anatomic Diagnosis.—Acute yellow atrophy of the liver; icterus; multiple hemorrhages; fatty degeneration of the heart; chronic Bright's disease.

Erlach,[17] in 1896, in a personal communication to Bandler,[14] reports the death of a patient from acute yellow atrophy of the liver, following the use of Billroth's mixture; total extirpation of the uterus was done for fibroids. SUPPLEMENT TO
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

ILLUSTRATING ARTICLE BY DRS. BEVAN AND FAVILL.

in bed and cried with fright, and had to be forcibly restrained. Sleep was induced by chloral and morphin.

January 7: The patient became deeply comatose. Face reddish, cyanosis, conjunctivæ icteric; pulse small and frequent, 150. Death occurred at 8:30 p. m.

Anatomic Diagnosis.—Cloudy swelling of heart, liver and kidneys. Icteric nutmeg liver.

G. E. Brewer,[2] in 1902, reports the following case:

Patient.—S. S., schoolboy, aged 12, was admitted to Roosevelt Hospital, April 29, 1901. Two days previously he had been seized with acute abdominal pain, accompanied by nausea and vomiting. There was slight elevation of temperature and increased pulse rate. Previous health was good.

Operation.—April 29, 1901: A perforated gangrenous appendix was found in a small abscess and removed. Anesthesia produced by chloroform lasted about twenty-five minutes. The second night after the operation was a comfortable one, and the following morning temperature was normal, pulse 76. During the day the temperature remained normal and pulse did not rise above 80.

Postoperative History.—The following night (third) he slept well until shortly after midnight, when he awakened suddenly without apparent cause and uttered an agonizing, piercing shriek expressive of terror. He failed to recognize people about him; he soon fell asleep, and rested quietly until morning. He was somnolent on the following morning. When aroused he would cry out and appear much frightened. Temperature 98.5, pulse 74. He was seen by Dr. Brewer at about 11 o'clock, and when awakened he screamed so loudly that he could be heard over the whole building and was the picture of abject terror. The paroxysms lasted from a few seconds to two or three minutes. There were no symptoms on part of nervous system. Consultation was held. Peculiar sweetish odor of breath was noted. At 6 p. m. temperature was normal; pulse during day was 80. Acetone and diacetic acid were found in the urine.

At 8 p. m., 400 centimeters of blood were withdrawn from median basilic vein, and 1,000 c.cm. of normal salt solution, to which were added 15 grams of chemically pure sodium bicarbonate were injected. The paroxysms of screaming became shorter and occurred less frequently. Circulation in extremities was slower; face became slightly cyanotic and eyes expressionless. Between 4 and 5 a. m. the condition began to grow worse. Respirations became shallow and rapid. The pulse was weaker; temperature rose rapidly to 103 F., and deep and progressive coma developed. Death occurred at 11 a. m. No autopsy.

Ballin,[20] 1905: Dec. 9, 1901: Appendectomy was done on a young man, aged 20 years; lead poisoning was a possible predisposing cause, under chloroform anesthesia. A small amount of chloroform was used.

Dec. 10, 1901, 9 a. m.: Temperature normal, pulse 100, patient restless and nauseated. Urine was drawn by catheter.

December 11: There was slight jaundice of skin and conjunctiva and slight vomiting several times. He was somewhat restless in the afternoon. Temperature 97.6 F., pulse 88. The jaundice increased; patient was restless and slightly delirious in the evening. There was vomiting of greenish fluid at 5 p. m.

December 13, 8 a. m.: Temperature 98 F., pulse 86; patient was delirious all night and was noisy; he slept at short intervals; he was apparently in deep coma at these times. He threw his arms and legs about wildly and was violent. By this time he presented the classical symptoms of acute yellow atrophy.

December 14: Temperature 100.4, pulse 108. Delirium and coma seemed to increase. Gradually there was subsidence of symptoms; patient was discharged from hospital on February 11.

Ballin discusses in this paper the possible relation to chloroform anesthesia and to toxins from diseased appendix.

Guthrie,[21] in 1903, reported the following cases:

CASE 1.—Woman, aged 41, was admitted to Glasgow Royal Infirmary on October 29, 1897. She had a tuberculous knee, from which she had suffered for the past twenty-seven years. During the past four years she had had occasional attacks of gallstone colic. Otherwise her health was good. The limb was put in carbolic acid dressings preparatory to operation. After twenty-four hours the patient vomited bile-stained matter; urine was greenish, becoming darker on standing. The dressings were immediately removed, but the patient remained seriously ill for eight days. After subsidence of vomiting, she remained well for nearly three weeks; urine was free from albumin and casts.

November 24: The knee was excised under chloroform. During the night, vomiting commenced and increased; nothing would stop it. Afternoon of November 26 patient was drowsy. At night she could not be aroused to answer questions. Urine was passed in small quantities and contained casts. She died comatose, November 27, three days after operation.

Autopsy.—Liver was markedly fatty. Heart was small, but musculature healthy. Kidneys were fatty, with some interstitial nephritis. Spleen was normal.

CASE 2.—Boy, aged 3, admitted under care of Mr. Burghard, for webbed fingers and toes, April 6, 1903. Patient was healthy looking and well nourished. Described as "dyspeptic," subject to "bilious attacks," "night terrors," and very passionate.

Operation.—April 7, at 3 p. m., webs between second and third fingers of each hand were divided under chloroform. Operation lasted twenty minutes. Chloroform was taken well.

Postoperative History.—On April 9 patient was slightly sick, drowsy and apathetic. On the afternoon of the same day, he became slightly, but distinctly, jaundiced. In the evening, he began to scream loudly, the screaming occurring in fits and paroxysms; he was seemingly semi-conscious. There was possible slight tenderness in liver region. Liver was slightly enlarged. Urine was passed involuntarily. Screams of shrill meningitic type continued until after 3 a. m., when they ceased after administration of chloral and bromids.

April 10: He lay in a practically unconscious state. Jaundice was about the same as on previous day. Liver could be felt two fingers' breadth below the ribs. Leucin and tyrosin were not found in urine. Toward night he became comatose. The conjunctival reflexes were lost. There was slight lateral nystagmus, especially in the left eye, with a tendency in both eyes to turn upward. Respirations were loud, quick, but not typical Cheyne-Stokes. Death occurred at 2:45 a. m. on April 11; 84 hours after the operation. Temperature was between 97 and normal throughout.

Autopsy.—Liver weighed 1 pound 12 ounces; pale and fawn-colored.

Microscopic Examination.—Osmic acid preparations showed a ring of fatty cells, occupying the outer zone of each lobule; intermediate zone, a few fatty cells; none in inner zone. Cloudy swelling and fatty degeneration. Small petechiæ were found in pleuræ. Brain, meninges, kidneys, suprarenal capsules, spleen and intestines were normal.

CASE 3.—Healthy-looking female child, aged 1 year and 10 months, was admitted to the Children's Hospital, Paddington-Green, under care of Mr. Burghard, February 24, 1898. Partial removal of nevus had been made in June of previous year. At 10 a. m., February 25, Mr. Burghard removed remaining portion of nevus under chloroform. The operation lasted twenty minutes. Carbolic acid was used only in strong mixture to purify skin at beginning of operation. Wound was dressed with cyanid gauze.

Postoperative History.—At 4:30 p. m. the child was slightly nauseated. Temperature, 9 p. m., 102. Child slept well during night; at 5 a. m. she awoke, restless and nauseated; at 7:15 a. m. she was restless, somewhat cyanosed, conscious, Pulse was feeble and rose to 136 and 160. At 11 a. m. the child vomited dark colored matter. At noon she became unconscious, though still restless and thirsty. At 2 p. m. there was a slight general convulsion. Saline injection was given. Death occurred twenty-eight hours after operation. Pulse was 160, temperature 106 at time of death.

---

[20] Ballin, Max: "Acute Yellow Atrophy of the Liver as a Sequela to Appendectomy." Ann. of Surg., 1903, xxxvii, p. 362.

[21] Guthrie, L. G.: "Some Fatal Effects of Chloroform on Children Suffering from a Peculiar Fatty Condition of the Liver." Lancet, 1903, II, p. 10.

Autopsy.—Liver weighed 13 ounces. Slight increase of fibrous tissue along portal canals. It was preserved in alcohol, preventing good demonstration of fat, but is reported as "undoubtedly fatty in places."

Case 4.—Girl, aged 3. Dr. Lack opened postpharyngeal abscess from behind sternomastoid. Chloroform was taken well. The operation lasted from ten to fifteen minutes. Twenty-four hours later the child appeared well, but was often nauseated. Temperature was 102 F. At 8 p. m., thirty-three hours after operation, the child had a "cold fit;" there was some shivering and extremities were blue and cold. Temperature rose to 107. Death occurred one-half hour later. Carbolic acid was used at operation, but no carboluria had developed. No autopsy was permitted.

E. G. Brackett,[3] in 1904, J. S. Stone and H. C. Low reported the following:

Case 1.—M. J. B., girl, aged 8, entered Children's Hospital October 6, 1903. There was extensive infantile paralysis involving most of the muscles of both lower extremities. During preceding year frequent attacks of severe and persistent vomiting, accompanied by marked prostration and rapid pulse, closely resembling condition existing first day of fatal one, may have been predisposing causes.

Operation and Postoperative History.—Oct. 10, 1903: The child was etherized and three tendons were transplanted. She took ether badly, was cyanotic and had rapid pulse. During recovery from ether the child vomited and then seemed comfortable and in good condition for twelve hours. She suddenly began to vomit; the pulse became rapid; rose to 190, and temperature to 106. Vomiting lasted about thirty hours. The child passed from restlessness into a delirious stupor, and died forty-two hours after operation, thirty hours after vomiting began. No test was made for acetone and diacetic acid in this case, but it was later recalled that the breath had a peculiar sweetish odor.

Autopsy.—Liver weighed 510 grams. Surface was smooth and irregularly mottled with yellowish areas from 3 to 5 cm. in diameter, scattered over a reddish-brown surface. Cross-section, yellowish-brown in color. Microscopically, sections of liver, spleen, kidneys and lung were negative.

Case 2.—Girl, aged 5½ years, entered Children's Hospital, November 16, 1903. Infantile paralysis, four years before, and contracted fasciæ, causing permanent flexion of the thighs. A slight trace of diacetic acid was present in urine.

November 17, 1903: Fasciæ at upper and outer part of each thigh were divided, open method. Operation was short, little ether being used.

Postoperative History.—At 11 p. m., thirteen hours after operation, she vomited a small amount of dark brown thin fluid; during the next ten hours she vomited several times. She slept in all three hours. When awake she was very restless and noisy. Twenty-four hours after operation the condition of patient was very poor. Extremities were cold; pulse weak and rapid; expression anxious; sweet odor of breath noticeable during morning. Twenty-six hours after operation 5 ounces of urine were passed, containing large traces of acetone and diacetic acid. Thirty hours after operation the child became delirious. Pulse was very weak. Thirty-six hours after operation, 12 ounces of 2 per cent. bicarbonate solution were given intravenously; also under each breast. On second morning following operation, child became dull and apathetic; she gradually lost consciousness and coma supervened. Odor of breath became more pronounced. Cyanosis was marked during last few hours. Temperature after operation remained at about 102.

Autopsy.—Liver surface smooth, and pale yellow; in places reddish color. Cut surface, pale yellow; oily and homogeneous. Fresh examination showed marked fatty infiltration. Kidneys, fatty infiltration.

Case 3.—Girl, aged 4, entered Children's Hospital, February 15, 1904, with double congenital dislocation of both hips. Right hip had been reduced five months previously under ether. Urine was acid, free from sugar and albumin. Three days after entrance to hospital patient was etherized, and in manipulating both femurs were broken.

Postoperative History.—Child was under ether between one-half and three-quarters of an hour. She recovered from the ether as usual. In the evening, pulse was weak and rose to 150. Twenty hours after operation, pulse became suddenly weak and rapid; the color was poor. The child seemed dull; no vomiting. Breath was sweet. Acetone and diacetic acid present in urine. During the day, the child grew rapidly worse and sank into restless coma; lips blue in spite of oxygen; drawn expression of face; eyes became sunken. At 6 p. m. salt solution was injected under both pectorals, followed by marked improvement in pulse and color. Temperature was 104; at 9:30 p. m. the child was able to recognize her mother. At midnight the condition grew rapidly worse. Temperature rose to 106 at 3 a. m. Coma returned. Child died at 5:30 a. m., twenty-three hours after first collapse, forty-three hours after operation.

Autopsy.—Liver large, pale yellow, with a pink color in places. Cut surface pale yellow; lobules indistinctly marked. Knife edge scraped up fatty material. Tissue broke easily on pressure. Kidney, considerable fat in epithelium of convoluted tubules.

Kelly,[22] in 1905, reported the following case:

Patient.—Schoolboy, aged 9. Service of Dr. H. W. Cushing. Operation, May 16, 1904, for appendicitis. Ether anesthesia. The condition of the appendix did not account for the patient's serious condition, so the abdomen was explored and nothing found. A sterile gauze wick was inserted into pelvis and to stump of appendix, and abdominal wound was closed. An area about 1 centimeter in diameter of slight edema and redness was found about 2 cm. from the tip of the appendix. The appendix contained a grape seed. The patient's general condition so grave that 250 c.c. (1-50,000) adrenalin salt solution were given. He was restless after operation. Urine was negative before operation.

Postoperative History.—May 18: Sweetish odor of breath continues. Patient mildly delirious and drowsy. Urine contains acetone and diacetic acid. Vomiting continues.

May 22: General condition markedly improved. Still occasional vomiting. Acetone and diacetic acid present in urine. No delirium, but patient is drowsy and resists daily dressing.

May 26: Occasional vomiting. Expression dull. Patient sleeps most of time; refuses everything by mouth. Acetone and diacetic acid in urine. Patient slowly failed, and in spite of active stimulation died at 11:05 p. m.

No autopsy. Examination of liver during operation was negative.

REVIEW OF SYMPTOMS.

The symptoms appear in from 10 to 150 hours after the anesthesia. The average of Guthrie's first series of ten cases being 37½ hours.

In Brewer's case, a boy of 12, following an operation for appendicitis lasting twenty-five minutes under chloroform, nothing unusual was noted immediately after. The second night following the operation was a comfortable one. He slept six hours; the next day his pulse was 76, and temperature normal. He was cheerful, happy, had no pain, and was hungry.

The following night, he slept quietly until shortly after midnight, when he suddenly awakened and without any apparent cause uttered a piercing shriek, which alarmed his nurse and mother. He continued to scream for several minutes, looked wildly about him, and apparently failed to recognize those around him. A few moments later he fell asleep and rested quietly until morning. The following morning he was distinctly somnolent, when aroused would cry out and appear frightened, but could easily be soothed by his mother.

---

[22] Kelly, Jas. A.: "Acid Intoxication: Its Significance in Surgical Conditions," 1905, xii, p. 161.

At 11 in the morning he awoke and again uttered an agonized cry. He continued to scream, so that he could be heard all over the building. Delirium was followed by coma. The face seemed slightly cyanosed; acetone and diacetic acid were found in the urine and blood. Death. No autopsy.

Brewer discusses the case and comes to the conclusion that it was an autointoxication, and considers ptomain poisoning, uremia and acetonemia, and concludes that acetonemia was the cause of death.

Brewer describes the three characteristic symptoms, as sweetish odor of the breath, delirium and rapidly fatal coma. Another symptom is that of air hunger, described by Kussmaul, evidenced by deep breathing and a bright red color of the mucous membranes (this was noted in our case), Cheyne-Stokes respiration and cold extremities.

Brackett, Stone and Low describe the following symptoms: Vomiting associated with collapse; a very weak and rapid pulse; an absence of fever until just before death; cyanosis in the fatal cases, causing extreme dyspnea; apathy and stupor alternating with periods of restlessness, at first, but in the fatal cases gradually deepening into coma and death; and the presence of acetone in the breath and urine.

Stocker describes the symptoms in his case as follows: The morning of the second day after the operation the patient, who had been doing well, became very restless, threw herself about in the bed, but mind was at first clear. The next day coma and death.

Guthrie says of symptoms:

> After recovery from the immediate effects of the chloroform there was usually an interval of a few hours at the end of which the child would begin to utter piercing cries at short intervals, disturbing the whole building by its shrieks, grinding its teeth, tossing, struggling and requiring constant attention lest dressings be torn off or fractured bones displaced. The pupils were often dilated, sometimes unequally, the face being flushed or pale, with a look of wild terror and anxiety. Consciousness was sometimes lost early and never regained; sometimes there were intervals in which the child would be dull and apathetic, but would answer rationally when addressed, and usually deny being in pain. Vomiting was a marked feature in all but one case. It was copious, frequent, persistent and the vomited matter sooner or later almost exactly resembled the dregs of beef tea.

In eight out of ten cases, the symptoms of a marked cerebral type were present, resembling maniacal delirium.

Temperature (10 cases): In 1 case it rose to 103 four hours after operation, and remained there throughout. In 2 cases it rose to 103.2, and 104.6, just before death. In 1 case it remained between 98 and 99. In 6 cases it varied from 99 to 102.

Two cases suggested meningitis, running unusually acute and rapid courses; except for absence of jaundice and hemorrhage, they might have been diagnosed as "acute yellow atrophy."

In Kelly's cases there was apathy, alternating with restlessness, vomiting occurring without apparent cause, following immediately on taking anything into the stomach, coma and death. The pulse was increased in rapidity, of decreased tension, and in some cases became very weak. Fever was absent except in severe cases, when the temperature would rise to 102 or 103. The face alternately pale or flushed, was at times expressive of great anxiety.

PREDISPOSING CAUSES.

Age, 1 to 10 years, 17 cases; 11 to 20 years, 3 cases; 21 to 30 years, 1 case; 31 to 40 years, 2 cases; 41 to 50 years, 2 cases. Age not mentioned in 5 cases.

Sex: Male, 9 cases; female, 18 case. Sex not mentioned in Bastianelli's three cases.

Possible predisposing or accessory causes are, alcohol, lead, carbolic acid, mercurial and iodoform intoxication. Other causes are homesickness, fright, change of food (Brackett, Stone and Low), intestinal fermentation and putrefaction; extensive fatty changes associated with infantile paralysis; starvation; sepsis. In pregnancy, in the presence of a dead fetus; the existence of a gangrenous mass, diabetes, carcinoma, anemic states from any cause and hemorrhage are also to be considered.

POSTMORTEM FINDINGS.

Liver: Fatty degeneration or infiltration occurred in 16 cases; acute yellow atrophy in 3 cases; icteric nutmeg liver in 1 case; no distinct liver changes mentioned in 4 cases; recoveries in 2 cases; no autopsy in 4 cases; total, 30 cases.

CHANGES IN OTHER ORGANS.

The following changes were noted in other parts of the body: Fatty degeneration of heart; different grades of nephritis; fatty degeneration of muscles of lower limbs; considerable venous congestion of brain; pyelitis; tuberculosis of bronchial lymph nodes and vertebræ.

CONCLUSIONS.

From the analysis of clinical and laboratory reports bearing on this subject, we believe that we are warranted in the following conclusions:

1. Anesthetics, especially chloroform (ether to a very limited degree), can produce a destructive effect on the cells of the liver and kidneys and on the muscle cells of the heart and other muscles, resulting in fatty degeneration and necrosis, very similar to the effects produced in phosphorus poisoning.
2. The constant and most important injury done is that to the liver.
3. This injury to the liver cells is in direct proportion to the amount of the anesthetic employed, and the length of the anesthesia.
4. Certain individuals exhibit an idiosyncrasy or a susceptibility to this form of poisoning which it is difficult to explain.
5. There are certain predisposing causes which favor this destructive effect of chloroform, among which are, (a) age—the younger, the more susceptible; (b) causes which lower the general vitality of the individual and probably the vitality of the liver cells, such as diabetes, previous recent anesthesias, infections from pus germs, diphtheria, intoxications from a dead fetus in the uterus, a gangrenous mass in the abdominal cavity, etc.; (c) exhaustion due to hemorrhage; (d) exhaustion due to starvation; (e) exhaustion due to wasting diseases, such as carcinoma; (f) lesions which have resulted in extensive fatty degenerations, such as occur in the limbs in infantile paralysis; (g) chronic diseases involving both liver and kidney, such as cirrhosis and nephritis.
6. As a result of this fatty degeneration and necrosis of the liver cells, toxins are produced either from the liver cells themselves or as a result of the failure of these cells to eliminate substances which, under normal conditions, they eliminate, but which under these abnormal conditions they fail to do, and these substances, therefore, may accumulate and produce toxic effects.

child vomited dark colored matter. At noon she became unconscious, though still restless and thirsty. At 2 p. m. there was a slight general convulsion. Saline injection was given. Death occurred twenty-eight hours after operation. Pulse was 160, temperature 106 at time of death.

Autopsy.—Liver weighed 13 ounces. Slight increase of fibrous tissue along portal canals. It was preserved in alcohol, preventing good demonstration of fat, but is reported as "undoubtedly fatty in places."

CASE 4.—Girl, aged 3. Dr. Lack opened postpharyngeal abscess from behind sternomastoid. Chloroform was taken well. The operation lasted from ten to fifteen minutes. Twenty-four hours later the child appeared well, but was often nauseated. Temperature was 102 F. At 8 p. m., thirty-three hours after operation, the child had a "cold fit;" there was some shivering and extremities were blue and cold. Temperature rose to 107. Death occurred one-half hour later. Carbolic acid was used at operation, but no carboluria had developed. No autopsy was permitted.

E. G. Brackett,[3] in 1904, J. S. Stone and H. C. Low reported the following:

CASE 1.—M. J. B., girl, aged 8, entered Children's Hospital October 6, 1903. There was extensive infantile paralysis involving most of the muscles of both lower extremities. During preceding year frequent attacks of severe and persistent vomiting, accompanied by marked prostration and rapid pulse, closely resembling condition existing first day of fatal one, may have been predisposing causes.

Operation and Postoperative History.—Oct. 10, 1903: The child was etherized and three tendons were transplanted. She took ether badly, was cyanotic and had rapid pulse. During recovery from ether the child vomited and then seemed comfortable and in good condition for twelve hours. She suddenly began to vomit; the pulse became rapid; rose to 190, and temperature to 106. Vomiting lasted about thirty hours. The child passed from restlessness into a delirious stupor, and died forty-two hours after operation, thirty hours after vomiting began. No test was made for acetone and diacetic acid in this case, but it was later recalled that the breath had a peculiar sweetish odor.

Autopsy.—Liver weighed 510 grams. Surface was smooth and irregularly mottled with yellowish areas from 3 to 5 cm. in diameter, scattered over a reddish-brown surface. Cross-section, yellowish-brown in color. Microscopically, sections of liver, spleen, kidneys and lung were negative.

CASE 2.—Girl, aged 5½ years, entered Children's Hospital, November 16, 1903. Infantile paralysis, four years before, and contracted fasciæ, causing permanent flexion of the thighs. A slight trace of diacetic acid was present in urine.

November 17, 1903: Fasciæ at upper and outer part of each thigh were divided, open method. Operation was short, little ether being used.

Postoperative History.—At 11 p. m., thirteen hours after operation, she vomited a small amount of dark brown thin fluid; during the next ten hours she vomited several times. She slept in all three hours. When awake she was very restless and noisy. Twenty-four hours after operation the condition of patient was very poor. Extremities were cold; pulse weak and rapid; expression anxious; sweet odor of breath noticeable during morning. Twenty-six hours after operation 5 ounces of urine were passed, containing large traces of acetone and diacetic acid. Thirty hours after operation the child became delirious. Pulse was very weak. Thirty-six hours after operation, 12 ounces of 2 per cent. bicarbonate solution were given intravenously; also under each breast. On second morning following operation, child became dull and apathetic; she gradually lost consciousness and coma supervened. Odor of breath became more pronounced. Cyanosis was marked during last few hours. Temperature after operation remained at about 102.

Autopsy.—Liver surface smooth, and pale yellow; in places reddish color. Cut surface, pale yellow; oily and homogeneous. Fresh examination showed marked fatty infiltration. Kidneys, fatty infiltration.

CASE 3.—Girl, aged 4, entered Children's Hospital, February 15, 1904, with double congenital dislocation of both hips. Right hip had been reduced five months previously under ether. Urine was acid, free from sugar and albumin. Three days after entrance to hospital patient was etherized, and in manipulating both femurs were broken.

Postoperative History.—Child was under ether between one-half and three-quarters of an hour. She recovered from the ether as usual. In the evening, pulse was weak and rose to 150. Twenty hours after operation, pulse became suddenly weak and rapid; the color was poor. The child seemed dull; no vomiting. Breath was sweet. Acetone and diacetic acid present in urine. During the day, the child grew rapidly worse and sank into restless coma; lips blue in spite of oxygen; drawn expression of face; eyes became sunken. At 6 p. m. salt solution was injected under both pectorals, followed by marked improvement in pulse and color. Temperature was 104; at 9:30 p. m. the child was able to recognize her mother. At midnight the condition grew rapidly worse. Temperature rose to 106 at 3 a. m. Coma returned. Child died at 5:30 a. m., twenty-three hours after first collapse, forty-three hours after operation.

Autopsy.—Liver large, pale yellow, with a pink color in places. Cut surface pale yellow; lobules indistinctly marked. Knife edge scraped up fatty material. Tissue broke easily on pressure. Kidney, considerable fat in epithelium of convoluted tubules.

Kelly,[22] in 1905, reported the following case:

Patient.—Schoolboy, aged 9. Service of Dr. H. W. Cushing. Operation, May 16, 1904, for appendicitis. Ether anesthesia. The condition of the appendix did not account for the patient's serious condition, so the abdomen was explored and nothing found. A sterile gauze wick was inserted into pelvis and to stump of appendix, and abdominal wound was closed. An area about 1 centimeter in diameter of slight edema and redness was found about 2 cm. from the tip of the appendix. The appendix contained a grape seed. The patient's general condition so grave that 250 c.c. (1-50,000) adrenalin salt solution were given. He was restless after operation. Urine was negative before operation.

Postoperative History.—May 18: Sweetish odor of breath continues. Patient mildly delirious and drowsy. Urine contains acetone and diacetic acid. Vomiting continues.

May 22: General condition markedly improved. Still occasional vomiting. Acetone and diacetic acid present in urine. No delirium, but patient is drowsy and resists daily dressing.

May 26: Occasional vomiting. Expression dull. Patient sleeps most of time; refuses everything by mouth. Acetone and diacetic acid in urine. Patient slowly failed, and in spite of active stimulation died at 11:05 p. m.

No autopsy. Examination of liver during operation was negative.

REVIEW OF SYMPTOMS.

The symptoms appear in from 10 to 150 hours after the anesthesia. The average of Guthrie's first series of ten cases being 37½ hours.

In Brewer's case, a boy of 12, following an operation for appendicitis lasting twenty-five minutes under chloroform, nothing unusual was noted immediately after. The second night following the operation was a comfortable one. He slept six hours; the next day his pulse was 76, and temperature normal. He was cheerful, happy, had no pain, and was hungry.

The following night, he slept quietly until shortly after midnight, when he suddenly awakened and without any apparent cause uttered a piercing shriek, which alarmed his nurse and mother. He continued to scream for several minutes, looked wildly about him, and apparently failed to recognize those around him. A few moments later he fell asleep and rested quietly until morning. The following morning he was distinctly somnolent, when aroused would cry out and appear frightened, but could easily be soothed by his mother.

---

[22] Kelly, Jas. A.: "Acid Intoxication: Its Significance in Surgical Conditions," 1905, xli, p. 161.

At 11 in the morning he awoke and again uttered an agonized cry. He continued to scream, so that he could be heard all over the building. Delirium was followed by coma. The face seemed slightly cyanosed; acetone and diacetic acid were found in the urine and blood. Death. No autopsy.

Brewer discusses the case and comes to the conclusion that it was an autointoxication, and considers ptomain poisoning, uremia and acetonemia, and concludes that acetonemia was the cause of death.

Brewer describes the three characteristic symptoms, as sweetish odor of the breath, delirium and rapidly fatal coma. Another symptom is that of air hunger, described by Kussmaul, evidenced by deep breathing and a bright red color of the mucous membranes (this was noted in our case), Cheyne-Stokes respiration and cold extremities.

Brackett, Stone and Low describe the following symptoms: Vomiting associated with collapse; a very weak and rapid pulse; an absence of fever until just before death; cyanosis in the fatal cases, causing extreme dyspnea; apathy and stupor alternating with periods of restlessness, at first, but in the fatal cases gradually deepening into coma and death; and the presence of acetone in the breath and urine.

Stocker describes the symptoms in his case as follows: The morning of the second day after the operation the patient, who had been doing well, became very restless, threw herself about in the bed, but mind was at first clear. The next day coma and death.

Guthrie says of symptoms:

> After recovery from the immediate effects of the chloroform there was usually an interval of a few hours at the end of which the child would begin to utter piercing cries at short intervals, disturbing the whole building by its shrieks, grinding its teeth, tossing, struggling and requiring constant attention lest dressings be torn off or fractured bones displaced. The pupils were often dilated, sometimes unequally, the face being flushed or pale, with a look of wild terror and anxiety. Consciousness was sometimes lost early and never regained; sometimes there were intervals in which the child would be dull and apathetic, but would answer rationally when addressed, and usually deny being in pain. Vomiting was a marked feature in all but one case. It was copious, frequent, persistent and the vomited matter sooner or later almost exactly resembled the dregs of beef tea.

In eight out of ten cases, the symptoms of a marked cerebral type were present, resembling maniacal delirium.

Temperature (10 cases): In 1 case it rose to 103 four hours after operation, and remained there throughout. In 2 cases it rose to 103.2, and 104.6, just before death. In 1 case it remained between 98 and 99. In 6 cases it varied from 99 to 102.

Two cases suggested meningitis, running unusually acute and rapid courses; except for absence of jaundice and hemorrhage, they might have been diagnosed as "acute yellow atrophy."

In Kelly's cases there was apathy, alternating with restlessness, vomiting occurring without apparent cause, following immediately on taking anything into the stomach, coma and death. The pulse was increased in rapidity, of decreased tension, and in some cases became very weak. Fever was absent except in severe cases, when the temperature would rise to 102 or 103. The face alternately pale or flushed, was at times expressive of great anxiety.

PREDISPOSING CAUSES.

Age, 1 to 10 years, 17 cases; 11 to 20 years, 3 cases; 21 to 30 years, 1 case; 31 to 40 years, 2 cases; 41 to 50 years, 2 cases. Age not mentioned in 5 cases.

Sex: Male, 9 cases; female, 18 case. Sex not mentioned in Bastianelli's three cases.

Possible predisposing or accessory causes are, alcohol, lead, carbolic acid, mercurial and iodoform intoxication. Other causes are homesickness, fright, change of food (Brackett, Stone and Low), intestinal fermentation and putrefaction; extensive fatty changes associated with infantile paralysis; starvation; sepsis. In pregnancy, in the presence of a dead fetus; the existence of a gangrenous mass, diabetes, carcinoma, anemic states from any cause and hemorrhage are also to be considered.

POSTMORTEM FINDINGS.

Liver: Fatty degeneration or infiltration occurred in 16 cases; acute yellow atrophy in 3 cases; icteric nutmeg liver in 1 case; no distinct liver changes mentioned in 4 cases; recoveries in 2 cases: no autopsy in 4 cases; total, 30 cases.

CHANGES IN OTHER ORGANS.

The [illegible] ere noted in other parts of the body: [illegible] of heart; different grades of nephritis; fatty degeneration of muscles of lower limbs; considerable venous congestion of brain; pyelitis; tuberculosis of bronchial lymph nodes and vertebræ.

CONCLUSIONS.

From the analysis of clinical and laboratory reports bearing on this subject, we believe that we are warranted in the following conclusions:

1. Anesthetics, especially chloroform (ether to a very limited degree), can produce a destructive effect on the cells of the liver and kidneys and on the muscle cells of the heart and other muscles, resulting in fatty degeneration and necrosis, very similar to the effects produced in phosphorus poisoning.
2. The constant and most important injury done is that to the liver.
3. This injury to the liver cells is in direct proportion to the amount of the anesthetic employed, and the length of the anesthesia.
4. Certain individuals exhibit an idiosyncrasy or a susceptibility to this form of poisoning which it is difficult to explain.
5. There are certain predisposing causes which favor this destructive effect of chloroform, among which are, (a) age—the younger, the more susceptible; (b) causes which lower the general vitality of the individual and probably the vitality of the liver cells, such as diabetes, previous recent anesthesias, infections from pus germs, diphtheria, intoxications from a dead fetus in the uterus, a gangrenous mass in the abdominal cavity, etc.; (c) exhaustion due to hemorrhage; (d) exhaustion due to starvation; (e) exhaustion due to wasting diseases, such as carcinoma; (f) lesions which have resulted in extensive fatty degenerations, such as occur in the limbs in infantile paralysis; (g) chronic diseases involving both liver and kidney, such as cirrhosis and nephritis.
6. As a result of this fatty degeneration and necrosis of the liver cells, toxins are produced either from the liver cells themselves or as a result of the failure of these cells to eliminate substances which, under normal conditions, they eliminate, but which under these abnormal conditions they fail to do, and these substances, therefore, may accumulate and produce toxic effects.

In conclusion, we believe that the dangers of late chloroform poisoning must be more generally recognized and understood; that the lessons from this study are the dangers of long chloroform anesthesias and chloroform anesthesias in patients suffering from the conditions which we cited favored its development; and, we must recognize the susceptibility of children to this form of poisoning. The problem of how to prevent these deaths confronts us unsolved. We have taken the first step in its solution, for we now recognize the cause of these deaths. We must work and find some way to prevent the occurrence of these serious and fatal accidents.

DISCUSSION.

Dr. Herbert C. Moffitt, San Francisco, stated that during the last three years he has seen in consultation six cases similar to the one reported. In each instance there had been some previous affection that might render the liver insufficient. One man had gummata of the liver, with gallstones. A woman had gallstones with frequent attacks of cholecystitis. A child had an attack of catarrhal jaundice some months before an operation under chloroform for mastoid disease. A young woman had had malaria for years, with enlarged liver and spleen, before she was operated on for acute appendicitis. Another young woman had had catarrhal jaundice some weeks before an exploratory laparotomy was done under chloroform. In four of the cases there was the clinical picture described by Dr. Bevan. It has been Dr. Moffit's rule of late, in view of such experience, to forbid the use of chloroform in any condition of suspected hepatic insufficiency.

Dr. Harry M. Sherman, San Francisco, said that Dr. Bevan has possibly explained something that puzzled him in a patient some time ago. A girl after an operation suffered from persistent vomiting and some jaundice with almost suppression of urine. One day the urine would contain casts with no albumin, and the next day albumin but no casts. Naturally Dr. Sherman thought there was some postoperative nephritis. To stimulate the kidney function he used salt solution under the skin, and the symptoms, including the vomiting, stopped and the patient began to take food, but the urine was not increased in quantity. Evidently it was not a case of nephritis and may not unlikely have been one that would fall into the class described by Dr. Bevan.

Dr. Woods Hutchinson, Portland, Ore., declared that the greater frequency of the occurrence of this condition in children is probably due to the fact that physicians have always thought it perfectly safe to use chloroform in children. It also probably explains the unexpectedly bad results that sometimes follow operations for gallstones, the liver being already disabled and unable to resist the attack of the anesthetic. The liver, Dr. Hutchinson said, is a poison filter and reduces toxins in the blood both from the portal and general systems. These toxins are changed into the harmless excretion, bile. The liver certainly is the organ which first fails in puerperal eclampsia, probably in most cases of Bright's disease, and is beginning to attract suspicion even in acute infections like pneumonia. In chronic poisoning by alcohol, arsenic or phosphorous the liver acts as chief protector of the system and first shows the result of the attack in cloudy swelling and cirrhosis. No matter what the disease, our patients die with one familiar group of symptoms—headache, convulsions, blindness, coma, Cheyne-Stokes respiration, which is called "uremia"—because urea is precisely the one substance which the liver is unable to form and hence is present in the blood in less amounts than usual. Uremia is the syndrome of liver failure. Just as long as the liver can destroy the toxins just so long the system will be able to resist.

Dr. Otto S. Binswanger, Portland, Ore., agreed with Dr. Bevan that death in chloroform poisoning is due to degeneration or death of the liver cells. Dr. Binswanger said that considering the part played in diabetic coma by oxybutyric and diacetic acids, he is inclined to believe that these acids may be responsible to some extent for the fatal results in these cases. In diabetes, he said, these acids cause an acidosis or a reduction in the alkalinity of the blood. They neutralize to some extent the carbonate of potassium or sodium. The carbonates are the chief agents for the removal of carbon dioxid. They are converted into bicarbonates, which in turn are broken up in the lungs into normal carbonates again and carbon dioxid, which latter substance is exhaled. If the quantity of carbonate of potash is reduced by the presence of oxybutyric and diacetic acid, naturally its functions as a carbon dioxid carrier will be reduced. The carbon dioxid will accumulate in the blood and give rise to carbon dioxid poisoning; exactly what happens is diabetic coma.

Dr. D. A. K. Steele, Chicago, reported one additional case of this comparatively rare condition. Two years ago he was called to see a girl aged 12, who was suffering from an acute attack of appendicitis. She had suffered an acident two weeks before by falling down stairs and fracturing both bones of her left forearm. The fracture was reduced under chloroform anesthesia. Dr. Steele had her removed to the Chicago Hospital and operated on her on the third day of her attack of appendicitis, finding an intensely inflamed and adherent appendix buried in a mass of lymph exudate, but not perforated. Chloroform was the anesthetic used during the operation. Everything went along normally for three days, when she began to be restless, delirious, and developed the classical symptoms referred to by Dr. Bevan. At the time of her death Dr. Steele attributed it to actonemia, but now he is convinced that it was a case precisely similar to the one described by Dr. Bevan.

Dr. A. D. Bevan said that Dr. Binswanger is quite correct in attributing certain results to acidosis. The primary cause is the destruction of the liver cells with the liberation in some way of a toxin which produces this symptom complex. Acetone and diacetic acid are to be regarded not as the essential cause, but as by-products in the pathologic process.

THE PRINCIPLE OF LIFE.*

MARSHALL LANGTON PRICE, M.D.

BALTIMORE.

> "The days of our age are three score years and ten; and though men be so strong that they come to four score years, yet is their strength then but labor and sorrow, so soon it passeth away and we are gone."

To many of us who travel along the level, but somewhat narrow pathway of scientific research, there doubtless comes the desire, to leave its beaten surface and to stray in these, border[illegible] where fact and fancy are so [illegible]; where the skies are always blue, the sunshine bright, and the flowers fresh and blooming; where substance appears as shadow and shadow substance and our pet hobbies, viewed with our indulgent paternal eyes, seem beautiful and spirited thoroughbreds. In this land, we can appropriately ask, in the words of the cynical Roman Governor of Judea (freed from the rigid limitations which science imposes), "What is truth?"

An excursion into these fields is not without benefit, even to the hard-headed man of science, and we have a precedent for invading the territory usually considered the exclusive possession of the poet, the artist, and the musician, from the highest possible source. M. Metchnikoff has recently made an excursion into this fascinating country and among the pebbles which he has gathered on its shores are a number of precious stones, which can not fail to add lustre to the crown of a man already a ruler in the field of scientific research.

I have chosen to-day (rather than to attempt the dif-

---

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

7. These toxins produce a definite symptom-complex which makes its appearance from 10 to 150 hours after the anesthesia. This symptom-complex consists of vomiting, restlessness, delirium, convulsions, coma, Cheyne-Stokes respiration, *cyanosis, icterus in varying* degree, and usually terminates in death.

8. It is probable that milder degrees of this poisoning are recovered from, and that the transient icterus noticed after chloroform anesthesia without other evident cause is due to such poisoning, and many cases which exhibit restlessness, fright, mild delirium, drowsiness, etc., after anesthesia may be due to the same cause.

9. This disease is an hepatic toxemia; the toxins producing it hepatic toxins; and possibly the previous condition making its development easily possible should be described as liver insufficiency. Just as we have for a long time recognized a condition, uremia, in which we find arising from a variety of noxious agents, anesthetics, poisons, infections, pregnancy, etc., affecting the secreting cells of the kidney and preventing their normal function, a pathologic condition, accompanied with a certain definite symptom-complex; so we must now, we believe, recognize a condition involving the liver in which we find from a variety of noxious agents (anesthetics, poisons, infections, pregnancy, etc.), affecting the secreting cells of the liver and preventing their normal function, a pathologic condition which we must describe as hepatic toxemia, accompanied with a certain symptom-complex, and showing certain changes postmortem.

We believe that the condition of acute fatty degeneration of the liver with resulting hepatic toxemia is as definite a pathologic entity as is acute pancreatitis with fat necrosis.

10. As by-products in this toxemia, but not as the essential poisons, are found acetone, diacetic acid and betaoxybutyric acid in the blood and urine.

11. Postmortem reveals fatty degeneration of the liver, fatty degeneration and mild degree of inflammation of the kidneys, and, in extreme cases, fatty degeneration of heart and other muscles. The lesion of the liver, we believe, to be the overshadowing and important one, and the one which is responsible for the symptoms and fatal result. The injury to the liver, in some cases, is so great as to result in practically a total destruction of the organ.

12. Somewhat similar hepatic toxemias resulting from fatty degeneration of the liver cells occur in other conditions, and are accompanied with very similar symptoms. In such conditions as phosphorus poisoning, diabetes, puerperal eclampsia, acute yellow atrophy of the liver.

13. This fatty degeneration of the liver with hep
toxemia following anesthesia is almost invariably
chloroform in the fatal cases. Ether is seldom
of a death of this kind.

14. This serious and even fatal late eff
form which has heretofore not been gene
must still further limit the use of th
dangerous agent.

15. The possibility of the develo
emia makes chloroform distinct
those cases in which there exi
seem to favor its develop
starvation, hemorrhage; th
from dead material; the p
as already cited, after inf
the liver. The suscepti

toxemia must be recognized. That chloroform is capable of producing these serious late poisonous effects is a strong argument against its employment, and an argument in favor of the more general use of ether; and yet *we are confronted at times with the Charybdis* of ether pneumonia, on the one hand, and the Scylla of chloroform hepatic toxemia, on the other.

16. The recognition of this danger of hepatic toxemia is a strong argument against the employment of chloroform for long anesthesia, as it can be shown that a two-hour chloroform anesthesia is almost invariably fatal to rabbits and guinea-pigs, from fatty degeneration and necrosis of the liver cells; and a two-hour chloroform anesthesia in man is an exceedingly dangerous thing.

17. These facts in regard to the late poisonous effects of anesthetics and the fact that the dangers increase with the amount of the drug employed, and with the length of the anesthesia form a strong argument in favor of rapid operating and in favor of limiting in every way possible the length of the anesthesia and the dose of the anesthetic. For example, time-consuming preparations of the patient should be made before, not after, anesthesia. In the light of this present knowledge, no surgeon can claim, as some have in the past, that after the patient is once asleep, that it makes no difference whether it requires one hour or two hours for the doing of an operation. In the light of this knowledge, for instance, three-hour breast amputations with the unnecessary ligation of fifty vessels, becomes bad surgery.

18. This problem seems to us a very important one, and worthy of the most careful study and research. At present, we are practically limited to chloroform and ether as general anesthetics. Each has its danger; each has its special field in which one is safer than the other. We have, as a rule, heretofore, employed chloroform in cases in which there was a previous lung or kidney lesion, and in children, with the idea that it was less likely to produce nephritis and pneumonia, and have used ether in the bulk of our work and felt that it was specially to be selected in heart lesions. We must now add new limitations, and
attempt to determ previous examination whether
there igh sufficiency, the

At the time of her death Dr. Steele attributed it to actonemia, but now he is convinced that it was a case precisely similar to the one described by Dr. Bevan.

Dr. A. D. Bevan said that Dr. Binswanger is quite correct in attributing certain results to acidosis. The primary cause is the destruction of the liver cells with the liberation in some way of a toxin which produces this symptom complex. Acetone and diacetic acid are to be regarded not as the essential cause, but as by-products in the pathologic process.

THE PRINCIPLE OF LIFE.*

MARSHALL LANGTON PRICE, M.D.

BALTIMORE.

> "The days of our age are three score years and ten; and though men be so strong that they come to four score years, yet is their strength then but labor and sorrow, so soon it passeth away and we are gone."

To many of us who travel along the level, but somewhat narrow pathway of scientific research, there doubtless comes the desire, to leave its beaten surface and to stray in those bordering fields where fact and fancy are so delightfully intermingled; where the skies are always blue, the sunshine bright, and the flowers fresh and blooming; where substance appears as shadow and shadow substance and our pet hobbies, viewed with our indulgent paternal eyes, seem beautiful and spirited thoroughbreds. In this land, we can appropriately ask, in the words of the cynical Roman Governor of Judea (freed from the rigid limitations which science imposes), "What is truth?"

An excursion into these fields is not without benefit, even to the hard-headed man of science, and we have a precedent for invading the territory usually considered the exclusive possession of the poet, the artist, and the musician, from the highest possible source. M. Metchnikoff has recently made an excursion into this fascinating country and among the pebbles which he has gathered on its shores are a number of precious stones, which can not fail to add lustre to the crown of a man already a ruler in the field of scientific research.

I have chosen to-day (rather than to attempt the dif-

---

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

7. These toxins produce a definite symptom-complex which makes its appearance from 10 to 150 hours after the anesthesia. This symptom-complex consists of vomiting, restlessness, delirium, convulsions, coma, Cheyne-Stokes respiration, cyanosis, icterus in varying degree, and usually terminates in death.

8. It is probable that milder degrees of this poisoning are recovered from, and that the transient icterus noticed after chloroform anesthesia without other evident cause is due to such poisoning, and many cases which exhibit restlessness, fright, mild delirium, drowsiness, etc., after anesthesia may be due to the same cause.

9. This disease is an hepatic toxemia; the toxins producing it hepatic toxins; and possibly the previous condition making its development easily possible should be described as liver insufficiency. Just as we have for a long time recognized a condition, uremia, in which we find arising from a variety of noxious agents, anesthetics, poisons, infections, pregnancy, etc., affecting the secreting cells of the kidney and preventing their normal function, a pathologic condition, accompanied with a certain definite symptom-complex; so we must now, we believe, recognize a condition involving the liver in which we find from a variety of noxious agents (anesthetics, poisons, infections, pregnancy, etc.), affecting the secreting cells of the liver and preventing their normal function, a pathologic condition which we must describe as hepatic toxemia, accompanied with a certain symptom-complex, and showing certain changes postmortem.

We believe that the condition of acute fatty degeneration of the liver with resulting hepatic toxemia is as definite a pathologic entity as is acute pancreatitis with fat necrosis.

10. As by-products in this toxemia, but not as the essential poisons, are found acetone, diacetic acid and betaoxybutyric acid in the blood and urine.

11. Postmortem reveals fatty degeneration of the liver, fatty degeneration and mild degree of inflammation of the kidneys, and, in extreme cases, fatty degeneration of heart and other muscles. The lesion of the liver, we believe, to be the overshadowing and important one, and the one which is responsible for the symptoms and fatal result. The injury to the liver, in some cases, is so great as to result in practically a total destruction of the organ.

12. Somewhat similar hepatic toxemias resulting from fatty degeneration of the liver cells occur in other conditions, and are accompanied with very similar symptoms. In such conditions as phosphorus poisoning, diabetes, puerperal eclampsia, acute yellow atrophy of the liver.

13. This fatty degeneration of the liver with hepatic toxemia following anesthesia is almost invariably due to chloroform in the fatal cases. Ether is seldom the cause of a death of this kind.

14. This serious and even fatal late effect of chloroform which has heretofore not been generally recognized must still further limit the use of this powerful and dangerous agent.

15. The possibility of the development of hepatic toxemia makes chloroform distinctly contraindicated in those cases in which there exist the conditions which seem to favor its development, i. e., diabetes, sepsis, starvation, hemorrhage; the presence of intoxication from dead material; the presence of fatty degenerations, as already cited, after infantile paralysis, and lesions of the liver. The susceptibility of children to this hepatic toxemia must be recognized. That chloroform is capable of producing these serious late poisonous effects is a strong argument against its employment, and an argument in favor of the more general use of ether; and yet we are confronted at times with the Charybdis of ether pneumonia, on the one hand, and the Scylla of chloroform hepatic toxemia, on the other.

16. The recognition of this danger of hepatic toxemia is a strong argument against the employment of chloroform for long anesthesia, as it can be shown that a two-hour chloroform anesthesia is almost invariably fatal to rabbits and guinea-pigs, from fatty degeneration and necrosis of the liver cells; and a two-hour chloroform anesthesia in man is an exceedingly dangerous thing.

17. These facts in regard to the late poisonous effects of anesthetics and the fact that the dangers increase with the amount of the drug employed, and with the length of the anesthesia form a strong argument in favor of rapid operating and in favor of limiting in every way possible the length of the anesthesia and the dose of the anesthetic. For example, time-consuming preparations of the patient should be made before, not after, anesthesia. In the light of this present knowledge, no surgeon can claim, as some have in the past, that after the patient is once asleep, that it makes no difference whether it requires one hour or two hours for the doing of an operation. In the light of this knowledge, for instance, three-hour breast amputations with the unnecessary ligation of fifty vessels, becomes bad surgery.

18. This problem seems to us a very important one, and worthy of the most careful study and research. At present, we are practically limited to chloroform and ether as general anesthetics. Each has its danger; each has its special field in which one is safer than the other. We have, as a rule, heretofore, employed chloroform in cases in which there was a previous lung or kidney lesion, and in children, with the idea that it was less likely to produce nephritis and pneumonia, and have used ether in the bulk of our work and felt that it was specially to be selected in heart lesions. We must now add new limitations, and attempt to determine by previous examination whether there is what might be called hepatic insufficiency, the conditions present which favor the development of the late poisonous effect of chloroform on the liver. Another way of solving this problem would be the discovery of new anesthetic agents, which do not carry with them these poisonous effects, or the employment of the present anesthetic in such a way as to avoid these dangers.

For instance, it has been suggested that chloroform and oxygen combined would prevent the poisonous effects of chloroform alone, and there is some evidence to support this view. This should be determined by special research.

Again, nitrous oxid and oxygen combined can be employed for long anesthesias, and experience may show that this mixture may prove to be very much safer than chloroform and ether. Although at present there is not enough evidence on which to base such a claim, in this connection I would cite the fact that the anesthetist in Dr. Bevan's surgical clinic, Dr. F. B. Moorhead, has found that after prolonged anesthesia with gas there is a marked decrease in the amount of hemoglobin, apparently a rather serious destructive effect on the blood, which may limit the use if this mixture.

In conclusion, we believe that the dangers of late chloroform poisoning must be more generally recognized and understood; that the lessons from this study are the dangers of long chloroform anesthesias and chloroform anesthesias in patients suffering from the conditions which we cited favored its development; and, we must recognize the susceptibility of children to this form of poisoning. The problem of how to prevent these deaths confronts us unsolved. We have taken the first step in its solution, for we now recognize the cause of these deaths. We must work and find some way to prevent the occurrence of these serious and fatal accidents.

DISCUSSION.

Dr. Herbert C. Moffitt, San Francisco, stated that during the last three years he has seen in consultation six cases similar to the one reported. In each instance there had been some previous affection that might render the liver insufficient. One man had gummata of the liver, with gallstones. A woman had gallstones with frequent attacks of cholecystitis. A child had an attack of catarrhal jaundice some months before an operation under chloroform for mastoid disease. A young woman had had malaria for years, with enlarged liver and spleen, before she was operated on for acute appendicitis. Another young woman had had catarrhal jaundice some weeks before an exploratory laparotomy was done under chloroform. In four of the cases there was the clinical picture described by Dr. Bevan. It has been Dr. Moffit's rule of late, in view of such experience, to forbid the use of chloroform in any condition of suspected hepatic insufficiency.

Dr. Harry M. Sherman, San Francisco, said that Dr. Bevan has possibly explained something that puzzled him in a patient some time ago. A girl after an operation suffered from persistent vomiting and some jaundice with almost suppression of urine. One day the urine would contain casts with no albumin, and the next day albumin but no casts. Naturally Dr. Sherman thought there was some postoperative nephritis. To stimulate the kidney function he used salt solution under the skin, and the symptoms, including the vomiting, stopped and the patient began to take food, but the urine was not increased in quantity. Evidently it was not a case of nephritis and may not unlikely have been one that would fall into the class described by Dr. Bevan.

Dr. Woods Hutchinson, Portland, Ore., declared that the greater frequency of the occurrence of this condition in children is probably due to the fact that physicians have always thought it perfectly safe to use chloroform in children. It also probably explains the unexpectedly bad results that sometimes follow operations for gallstones, the liver being already disabled and unable to resist the attack of the anesthetic. The liver, Dr. Hutchinson said, is a poison filter and reduces toxins in the blood both from the portal and general systems. These toxins are changed into the harmless excretion, bile. The liver certainly is the organ which first fails in puerperal eclampsia, probably in most cases of Bright's disease, and is beginning to attract suspicion even in acute infections like pneumonia. In chronic poisoning by alcohol, arsenic or phosphorous the liver acts as chief protector of the system and first shows the result of the attack in cloudy swelling and cirrhosis. No matter what the disease, our patients die with one familiar group of symptoms—headache, convulsions, blindness, coma, Cheyne-Stokes respiration, which is called "uremia"—because urea is precisely the one substance which the liver is unable to form and hence is present in the blood in less amounts than usual. Uremia is the syndrome of liver failure. Just as long as the liver can destroy the toxins just so long the system will be able to resist.

Dr. Otto S. Binswanger, Portland, Ore., agreed with Dr. Bevan that death in chloroform poisoning is due to degeneration or death of the liver cells. Dr. Binswanger said that considering the part played in diabetic coma by oxybutyric and diacetic acids, he is inclined to believe that these acids may be responsible to some extent for the fatal results in these cases. In diabetes, he said, these acids cause an acidosis or a reduction in the alkalinity of the blood. They neutralize to some extent the carbonate of potassium or sodium. The carbonates are the chief agents for the removal of carbon dioxid. They are converted into bicarbonates, which in turn are broken up in the lungs into normal carbonates again and carbon dioxid, which latter substance is exhaled. If the quantity of carbonate of potash is reduced by the presence of oxybutyric and diacetic acid, naturally its functions as a carbon dioxid carrier will be reduced. The carbon dioxid will accumulate in the blood and give rise to carbon dioxid poisoning; exactly what happens is diabetic coma.

Dr. D. A. K. Steele, Chicago, reported one additional case of this comparatively rare condition. Two years ago he was called to see a girl aged 12, who was suffering from an acute attack of appendicitis. She had suffered an acident two weeks before by falling down stairs and fracturing both bones of her left forearm. The fracture was reduced under chloroform anesthesia. Dr. Steele had her removed to the Chicago Hospital and operated on her on the third day of her attack of appendicitis, finding an intensely inflamed and adherent appendix buried in a mass of lymph exudate, but not perforated. Chloroform was the anesthetic used during the operation. Everything went along normally for three days, when she began to be restless, delirious, and developed the classical symptoms referred to by Dr. Bevan. At the time of her death Dr. Steele attributed it to actonemia, but now he is convinced that it was a case precisely similar to the one described by Dr. Bevan.

Dr. A. D. Bevan said that Dr. Binswanger is quite correct in attributing certain results to acidosis. The primary cause is the destruction of the liver cells with the liberation in some way of a toxin which produces this symptom complex. Acetone and diacetic acid are to be regarded not as the essential cause, but as by-products in the pathologic process.

THE PRINCIPLE OF LIFE.[*]

MARSHALL LANGTON PRICE, M.D.

BALTIMORE.

> "The days of our age are three score years and ten; and though men be so strong that they come to four score years, yet is their strength then but labor and sorrow, so soon it passeth away and we are gone."

To many of us who travel along the level, but somewhat narrow pathway of scientific research, there doubtless comes the desire, to leave its beaten surface and to stray in those bordering fields where fact and fancy are so delightfully intermingled; where the skies are always blue, the sunshine bright, and the flowers fresh and blooming; where substance appears as shadow and shadow substance and our pet hobbies, viewed with our indulgent paternal eyes, seem beautiful and spirited thoroughbreds. In this land, we can appropriately ask, in the words of the cynical Roman Governor of Judea (freed from the rigid limitations which science imposes), "What is truth?"

An excursion into these fields is not without benefit, even to the hard-headed man of science, and we have a precedent for invading the territory usually considered the exclusive possession of the poet, the artist, and the musician, from the highest possible source. M. Metchnikoff has recently made an excursion into this fascinating country and among the pebbles which he has gathered on its shores are a number of precious stones, which can not fail to add lustre to the crown of a man already a ruler in the field of scientific research.

I have chosen to-day (rather than to attempt the difficult, if not impossible task of adding to this session on water, which has already been so fully and ably discussed) to consider some of those elementary principles affecting human life; always so near to us as hygienists; as a sort of *confession fidei,* if I may be allowed to make such for this congregation.

---

[*] Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

As the faithful in the three Catholic religions never part company without the confession of faith contained in the Nicene or Apostolic creed, so it seems to me proper that we should not separate in our annual meetings without reiterating some of those elementary principles which underlie our endeavors. (A practice which I commend to the consideration of our future officers.)

The primary objects on which our complicated sanitary procedures are built are, after all, the preservation and lengthening of human life; or, the problem of hygiene stated in biologic form, is the preservation, conservation and increase of those metabolic functions of the cell, the resultant of whose sum total we recognize as the phenomenon of life. We can properly leave in other hands the equally important objects of human usefulness and happiness.

I have endeavored to-day to analyze some of these elementary principles connected with a problem, obscure, but of vital interest, and in their consideration to attempt to open a door which has remained closed for over 8,000 years of human history. This problem concerning which are probably the most important and interesting of Metchnikoff's recent investigations, is that of "age," perhaps the most mysterious and insoluble of the problems with which human philosophers have attempted to deal. The question, Why should a man die? is only secondary in importance to the centuries old question of Job, "If a man die shall he live again?"

M. Metchnikoff may be credited with being the first scientist who has directly investigated this problem and who has given us anything bearing on its causation. The discordance of even the tentative theory which he pronounces will appear in the further analysis of the biologic principles connected with senility.

In the investigation of this problem, Metschnikoff has made examination of the tissues and cells of numerous men and animals who have died at advanced years. He ascribes the failure of function which we recognize as age to the inability of the highly differentiated cells to resist the action of the phagocytes which he has found, particularly in the nervous tissues, to attack the former and to destroy them by the usual digestive activities. It will be noted that this deficiency of the aged cell which M. Metschnikoff has observed—though of the utmost importance in the fate of the organism—is merely one of the defects, of which there are probably many, inherent in the senile cell, and its presence there does not explain the important problem of why the aged cell should be deficient at all; and it is difficult, indeed, to conceive, why the one-thousandth or ten-thousandth descendant of a cell should be less able properly to perform its function than the one-hundredth or five-hundredth descendant.

From our present knowledge, we can only advance three theories that would properly account for the condition known as senility in an animal organism:

First, that the failure of the cells is due to successive and repeated inflammations, and that as a result of this action of pathogenic organisms and toxins the specific cells are destroyed and are replaced by connective tissue cells, with the formation of fibrous or scar tissue, which, of course, is unable to perform the functions of the cells which it replaces.

Second, that the failure of the cell is a nutritive one, the cell becoming unable with the advance of time, to maintain and to continue those metabolic processes which are required of it in the performance of its special functions.

Third, that the failure of the cell is due to the loss of the properties which enable it to resist and to overcome the constant activities of pathogenic organisms and toxins.

If we accept the first hypothesis we must believe, other things being equal, that the functioning power of the organism is to be measured wholly by the number of cells which it contains capable of performing their specific metabolic functions, that the physiologic age of the organism will depend in turn on the number and extent of the inflammatory and toxic processes to which it has been subjected. That this substitution of functionating cells by connective tissue cells in the form of a fibrous reticulum or scar is a decided factor in the "age" of the organism there can be no doubt, but the hypothesis that it is the only condition connected with what we know as old age, is open to numerous objections.

In the first place, we would expect to find those organisms which had undergone repeated general inflammations always more advanced in the period of physiologic age than other organisms of the same years, not subjected to the results of inflammations or toxemias—a supposition not in accord with the general clinical experience of the present generation.

Second, we find the changes incident to age in certain organs and tissues which, so far as we can ascertain, have undergone neither inflammations nor toxemias. For example, in the skin of the old man we find an atrophy, a loss of elasticity, and a tendency to malignant and other morbid proliferations which are evidently independent of inflammatory or toxic influences; nor do the commonly recognized inflammations of the skin seem to have any influence in producing these degenerative changes.

The third and most forcible objection to accepting this hypothesis (and probably the most characteristic deficiency of the senile cells) is the loss of the power of reproduction and regeneration. This regenerative deficiency can not have any relation to local or general inflammation, and the general rule seems definite for all organisms of the same species: *The regenerative power of the cells composing an organism are inversely proportional to the age of the organism.* Aside from this most striking deficiency in function, we might ascribe many of the tissue degenerations to another condition practically always associated with age, viz., to a diminished blood supply dependent on arteriosclerosis. We see these degenerations frequently, however, in tissues possesed of an abundant blood supply, and in which arteriosclerosis is absent. On the other hand, involution degenerations do not occur in the tissues of the young, even when a local arteriosclerosis is present or when the vascularity of the part is diminished by reason of other conditions.

Arteriosclerosis does not in itself constitute age, although it is probably the best measure which we possess of senility in the general cellular system. We probably have in the vessels, preceding and causing their eventual sclerosis, both diminished resistance to bacteria and toxins and loss of regenerative powers of the endothelium, all acting to produce the substitution of the endothelial cells by fibrous tissue. The production of fibrous tissue is itself, no doubt, directly associated with the loss of the power of regeneration on the part of the ectodermic or endodermic cells which it usually replaces.

We are then compelled to fall back on one of the two remaining hypotheses—either the senile condition of the cell (of which loss of the regenerative function is the prominent sign) is due to failure of the metabolic activities connected with nutrition, or it is due to lack of power to neutralize and to oppose the action of pathogenic organisms, or of toxic substances.

On closer analysis, we perceive both these former deficiencies to be present and inherent in the senile cell, in common with the loss in the power of regeneration, though the latter deficiency is most evident.

Whether we regard the depreciation of the cell as metabolic or bacteriolytic the failure must be primarily nutritive, as Metchnikoff has clearly shown that the antitoxic properties of a cell are closely connected with its nutrition and growth and are probably only specific modifications of the function of nutrition to adapt the cell to the special necessities of the organism. There must be some common source from which the cell derives its metabolic, bacteriolytic and antitoxic functions. As these functions diminish with advancing years, it is natural to suppose that the source from which they are derived diminishes in like manner; our first step in the investigation of this source, therefore, would be the comparative investigation of the senile and juvenile cells. The comparative analysis of the young and old cell does not as yet show any perceptible difference in their chemical composition, nor can we detect with the microscope any structural divergence; it is in their biologic functions and properties alone that we detect their dissimilarity. That the deficiency of the senile cell is a chemical one we have reason to believe by analogy with other functionating cells. When we speak of a cell being worn out or exhausted we infer that some substance which the cell previously contained has become deficient during the performance of its functions.

We judge from the constant chemical composition of specific cells of all ages that such substance, if existant, must be present in minute quantity.

It is on the theory of the existence of this substance that I have formulated my hypothesis:

1. *That every living cell, human or animal, contains a specific substance necessary to its functions.*

2. *That this substance becomes progressively exhausted during the life of the organism, to a certain stage, beyond which the metabolic activities of the cell are brought to a close.*

3. *That this substance alone, of all the materials entering into the composition of the cell, is not renewed after a certain early stage of the life of the organism.*

4. *That the age and duration of the activities of the cell are dependent on the amount of this substance with which it is primarily endowed.*

5. *That the primary endowment of the cell occurs at a very early period of its growth.*

This substance I have called bioplasmine.

We may illustrate the relation of a bioplasmine to the organism as follows: The individual may be compared to a lifeboat cast adrift from a sinking ocean liner (the parent organism), the members of the crew representing the individual cells, and a cask of water the supply of bioplasmine from the ship's stores. This supply may be exhausted quickly or slowly, according to the demands made on it, but it will never be renewed. The water, it will be further noted, is not equally apportioned among the members of the crew.

As all the materials of the cell, except this specific cell substance, are constantly renewed, the bioplasmine molecule occupies a place apart in the cell substance.

That this molecule is independent of the composition and activities of the cell substance proper we can infer from the apparently identical composition of the juvenile and senile cells. The specific chemical composition of the cell remains the same, according to our present means of chemical analysis, whatever its age, and it is mainly by the loss of power of reproduction and regeneration and the bacteriolytic functions that we can perceive its gradual decline and final dissolution.

As regards the nature of bioplasmine, it can only be said that it remains very much the same substance during life, except that its activities become progressively lessened. This would lead us to believe that we have to deal with a comparatively large proteid molecule which has the power of splitting off some body essential for the metabolic changes concerned with nutrition. This substance may be called metaboline or nutrescine. The bioplasmine molecule may be represented by the following graphic formula (Fig. 1):[*]

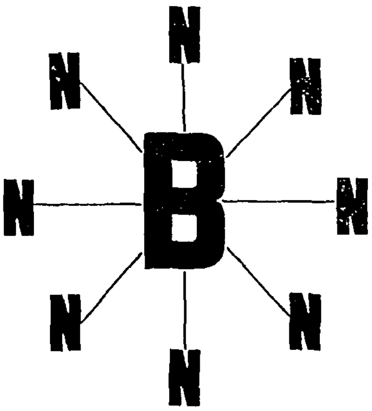

Fig. 1.—Bioplasmine.

It is not likely that this substance is formed by a single process of combination, but rather that it is the result of a series of anabolic changes.

For its origin I believe that we must look to the very earliest of the processes leading to the formation of the embryo, preceding the time when the activities of formation and growth become macroscopically manifest.

Judging by analogy, we would suppose that the substance called bioplasmine, like other substances concerned with metabolism (such as the enzymes), had a preliminary body or zymogen from which it is generated. This substance may be called *bioplasminogen*. The transformation of bioplasminogen into bioplasmine taking place in the cells during the act of absorption. We have first to consider, then, the formation of bioplasminogen.

Some of the reasons have already been briefly mentioned for placing the time of the formation of bioplasminogen in the early history of the embryo, and there are further reasons for supposing that this formation takes place at the beginning of the life of the organism as a separate entity, viz., during the act of conception. The strong physical attraction between the male and female sexual elements would indicate a basis in a strong chemical affinity, and it is during this act that a substance enters the composition of the cell that can not be renewed during its later life.

---

[*] In all the figures B represents the central radicle proteid or binding group; and N the "side-chain" group spoken of as metaboline or putrescine.

The action of the male on the female cell would appear primarily to be one of ionization, and it is possible that we may find in the nutrescine molecule a substance peculiarly capable of ionic dissociation. The nutrescine molecule need not necessarily be of proteid composition, but may consist of various mineral elements or salts combined in such a manner as to produce the degree of ionization necessary in proteid anabolism.

Loeb believes that the primary action of the male on the female cell, leading to the formation of the morula mass, to be one of ionization. As is well known, he has been able to produce the early stages of the processes following impregnation, leading even as far as the formation of imperfect embryos, by the action of dilute solutions of various salts, particularly potassium cyanid, on the unimpregnated ovum. It is interesting to note that by the action of this salt an extreme prolongation of life in certain low animal forms has been possible. It is possible that cyanogen or a similar radicle may enter into the composition of the nutrescine molecule of the bioplasmine body.

We may conceive of three, out of many intermediary stages, in the formation of bioplasmine. The specific elements leading to its production are doubtless to be found in the elementary male and female cells. These cells we may consider to contain substances possessed of strong mutual affinities which may be named spermatoplasmon and ovoplasmon, respectively (Fig. 2). By their interaction, ovoplasmon and spermatoplasmon give rise to bioplasminogen; this body is then taken up by the cells, probably during their active segmentation, and by them further transformed during absorption into bioplasmine. There would be no reason to suppose that the cells retain this power of transforming the bioplasminogen molecule and of absorbing it indefinitely, and it is probable that this function is at an end after the embryonic cells have ceased their active segmentation, i. e., after the formation of the morula mass.

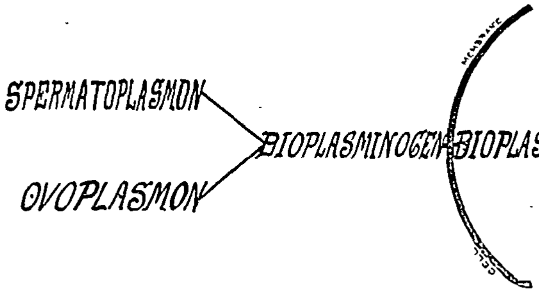

Fig. 2.—Formation of Bioplasmine.

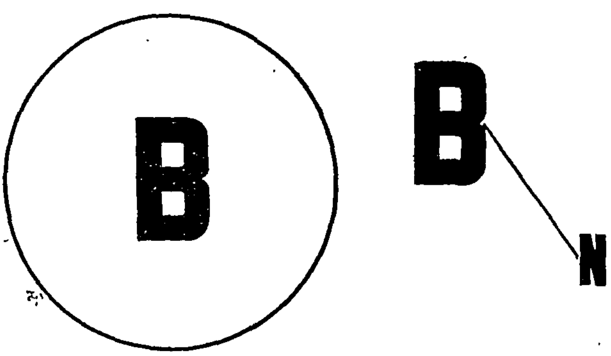
The bioplasmine molecule is apparently quite stable, though it is capable of disassociation with great readiness under the proper stimulus.

Starting with the graphic formula (Fig. 1), bioplasmine undergoes progressive decomposition by the loss of successive nutrescine molecules, the completed reduction only occurring theoretically with the loss of all the N/ molecules (Fig. 3). More probably, however, a complete reduction would not be possible through the forces of vital chemistry; the end-product would be better represented theoretically by the graphic formula in Fig. 4. The power of parting with the N/ molecule which the bioplasmine body possesses when subjected to the action of certain stimuli depends on a sort of instability which makes it readily capable of decomposition under physiological influences. It becomes progressively more stable as the number of N/ molecules diminish until it reaches a stage where the physiologic stimuli are no longer capable of causing dissociation, so that practically the metabolic activities of a cell never survive to a stage where the whole molecule would correspond to the graphic formula shown in Fig. 3 or 4, but would cease when the number of N molecules was still relatively large.



Figs. 3 and 4.—Reduction of Bioplasmine.

We may use these formulæ as a graphic means of representing the physiologic age of the cell according to the state of the bioplasmine molecule which it contains. Dividing the age of the cell into three periods, we can represent the youthful, middle-aged, and senile cells as is shown in Fig. 5.

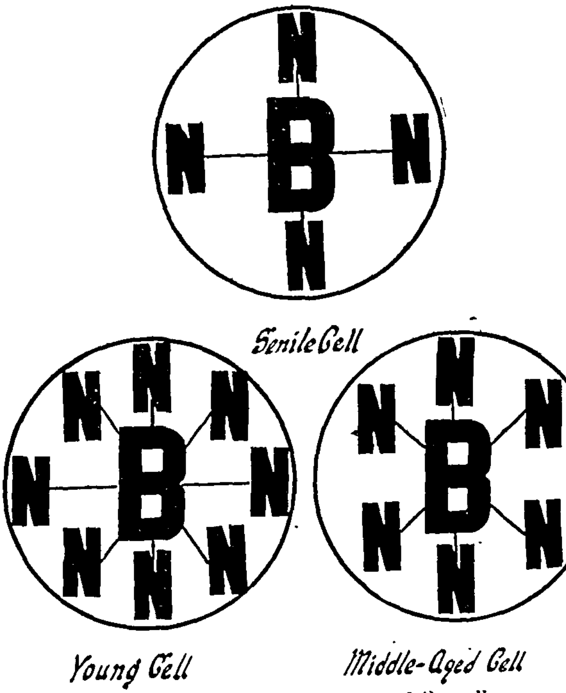


Fig. 5.—Three periods in age of the cell.

The molecule N probably represents the essential body both in metabolic processes and in the formation of antitoxins and bacteriolysins, so as the cell becomes older not only do its metabolic functions become diminished, but it is increasingly less able to cope with pathogenic organisms and toxins.

When the bioplasmine molecule reaches a certain degree of stability, the cell becomes eliminated either by the action of parasites or by the substitution of cells endowed more liberally with the essential metabolic molecule.

The supply of bioplasmine does not seem to be equally distributed among the various cells, the connective tissue cells seem to be most liberally endowed and the more highly differentiated cells appear to become deficient long before there is any marked diminution in the capabilities of the cells of the mesoderm. If we take the regenerative powers of the cell as a measure of the amount of bioplasmine with which it was originally endowed, we find a marked difference in the stage at which senility becomes evident in cells possessed of different functions. The nerve cells have been considered to have no power of reproduction after the time when they have taken on their special function, but it has recently been shown that even nervous cells have a power of regeneration during the earlier periods of the life of the animal.

The chemical properties of bioplasmine must be considered more or less unique. It seems under ordinary conditions to possess a certain stability, yet when the proper stimulus is applied it appears to part with one or more of its nutrescine molecules with great facility. Its action is different from most of those substances which cause chemical or physiologic combination by their presence in minute quantity, inasmuch as the N/ molecules do not undergo decomposition and recomposition as do bodies having the so-called catalytic action (such as the ferments), but they enter into direct combination with the nutritive bodies formed and are thus permanently lost with the cellular katabolisis. Bioplasmine is the one substance of the materials composing the cell which is not renewed during nutritive processes. It thus has a place apart from the cellular chemical changes which it influences indirectly by parting with its nutrescine molecules.

In order to arrive at some suggestive conclusion as to the nature and mode of action of this body whose existence I have assumed, I have further taken up the study of regeneration and reproduction on the basis of this theory, as these functions best mark, as already stated, the difference between the young and old cell. From this theory I have endeavored to formulate rules under which reproduction not only may occur, but to determine the conditions under which it necessarily must occur if these conditions are present in the cell and its surrounding medium. These rules may be presented in the following form:

In the young cell a certain stimulus arises from the surrounding medium for the production of N bodies, which production occurs in excess, a certain number combining to form preliminary substances which are to undergo further anabolic changes, finally to convert them into the proximate principles of the cell, the remainder being left free and uncombined within the cell. As the stimulus arises from the surrounding medium, the production of N/ bodies is most marked at the poles of the cell (which are most exposed to the medium). This overproduction soon reaches such a stage that the plasma elements can not enter the cell in sufficient amount to combine with the N bodies without an increase in the area presented by the cell to the surrounding medium. This increase is then accomplished by division of the cell, which is a necessity in order to adapt it to the changed conditions. Mitosis is favored by molecular tension resulting from the accumulation of N bodies at the poles of the cell, where the influence of the surrounding medium is most marked. This process is the basis of the chemical and vital forces of mitosis, with the physical evidences of which we already are familiar. The basis of mitosis thus is purely chemical and is determined by a stimulus derived from the plasma.

The action may not be wholly one of principles in solution in the plasma; certain cells, particularly the leucocytes, seem to have the power of exciting cell proliferation. The chemical basis of mitosis is represented graphically in Fig. 6.

The influences leading to cell regeneration are not wholly to be found in the plasma, but also depend on the number of cells among which the stimulus must be divided. The cell deficiency which occurs from traumatism is no doubt a potent influence in determining regeneration, but equal importance is to be ascribed to the effusion of lymph and to the presence of leucocytes which always collect in numbers where there is any considerable destruction of fixed cells.

It is possible that different chemical compounds act as stimuli in reproduction, on the one hand, and in regeneration, on the other. We can not consider, for example, the formation of scar tissue as the result simply of reproduction of the connective tissue cells; a special stimulus seems to be necessary to cause the connective tissue cells to form a scar. This stimulus may be derived from the mononuclear leucocytes also, as scar tissue forms in the infectious granulomata, in which the polymorphonuclear leucocytes are largely absent. There are doubtless many intermediary bodies capable of combining with the bioplasmine radicle, of which the leucocytic stimulant may be one.

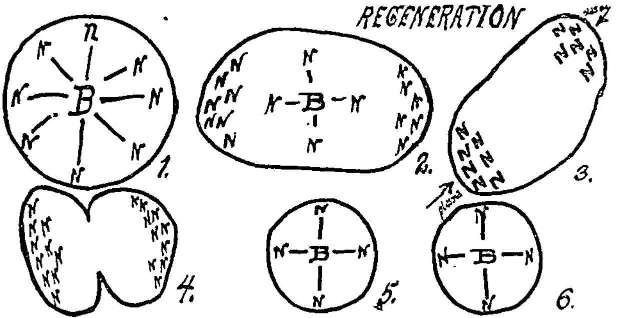

Fig. 6.—Regeneration.

The question of abnormal regeneration may be briefly touched on. Morbid proliferations play an important, if not essential, part in benign and malignant neoplasms. The bioplasmine molecule must be concerned in these processes, though not necessarily directly. The influence of the bioplasmine molecule may occur in one of two ways—either the bioplasmine molecule becomes disorganized and parts with a number of nutrescine molecules far in excess of the physiologic needs of the organism, or the same result is produced under the action of a pathologic stimulus derived from the plasma. In producing the fatal result we have both the directly injurious action of the morbid growth or growths and the exhaustion of the essential nutritive principle. It is the latter factor which is most active in producing the general organic nutritive deficiency spoken of as cachexia.

Regeneration and growth, both normal and pathologic, take their character from heredity, using the term in its largest significance, and the subject of heredity is itself capable of further analysis along these lines. The principle on which heredity depends can not be limited to the individual, family or race, but must be extended to species as well. That the properties of a cell should persist through several generations points to the conclusion that the persistence depends on persistent chemical and physical composition of the cell. Or using the term in the sense of qualities persisting in the descendant cells, heredity may be defined as the persistence of the chemical composition of a cell through several generations of descendants.

The problem becomes more complex when we deal with the higher organisms, because among these are specifically differentiated cells, possessed of varying properties and capabilities. While these properties and capabilities are derived from the ancestor, the problem is much complicated by the necessary inter-relations of the component cells forming the organism. Further, the individual functions and capabilities of the cell are more numerous. The character of the individual depends on his nutrition, the term nutrition signifying in general the chemical and physical composition of the cell in relation to its medium. In the persistence of the chemical cellular endowment in the ancestors we have the cause of the similarity of individuals forming the family, race or species.

Very generally stated, the characteristics of an individual depend on two factors: 1. The individual nutritive capabilities of the component cells. 2. The harmonious action of the various classes of cells. Since the nutrition of a cell is dependent on the bioplasmine molecule, this body must play an essential, if not the only, part in determining heredity.

Concerning the influence of bioplasmine in heredity, we have to consider in the individual the following factors:

As regards the individual cells: 1. The amount of bioplasmine with which the original cells are endowed. 2. The character of the bioplasmine molecule, particularly its facility of dissociation under appropriate stimuli; as regards the organism as a whole, the harmony or lack of harmony of nutritive energy between the variously differentiated cells.

The latter factor determines whether the resultant will be large or small.

Generally, we will look for a maximum resultant in certain functions and a minimum in others. We look for a certain similarity in the successive similar functions in the individual, and these similarities we can group under the head of characteristics.

It may be permissible to speculate on the practical results that might accrue from the isolation of a specific metabolic body from the cell. If, for instance, we could isolate and determine the properties of bioplasmine, we might consider that we had made a step toward the almost indefinite prolongation of life. The problem which would present itself would be the renewal of the tissue supply of bioplasmine whenever the original supply gave evidences of becoming exhausted. There are many difficulties in the way of renewing this material in the body, even if we had successfully isolated and manufactured it. It is probable that bioplasmine, as such, is not absorbed by the proliferating cell, but must be absorbed as the preliminary body which has been spoken of as bioplasminogen; moreover, it would not be reasonable to expect a matured cell to take up bioplasminogen if it could be injected into the blood of the organism, as it is probable, as already suggested, that the cell only possesses the function of absorbing bioplasminogen during a very early period of its embryonic life. The function may cease as early as the formation of the morula mass. It may be possible that we could extract from the embryonic cell some substance that would enable the matured cell to absorb bioplasminogen and to convert it to its uses.

I would consider, however, that the first advance to be made in prolonging life would be by the use of substances capable of stimulating the bioplasmine to yield a further quantity of its nutrescine molecules when this could no longer be accomplished by the physiologic stimulus. It is not likely that the bioplasmine molecule is ever so far reduced during life that there does not remain a considerable number of N/ molecules in combination.

It is to the physiologic chemist that we must turn for the elucidation of these and of most other obscure problems of the medicine of the future, and we can expect them to respond with the same enthusiasm with which they have already surmounted so many obstacles. A careful differential analysis of the juvenile and senile organs will well repay the time spent, though it may be yet too early to hope for the isolation of a body so unstable and present in such small amounts as the one we have described.

It is not too much to expect of the scientists of the future that they may enable our descendants of 1,000 or 5,000 years hence to realize or to surpass the years of Noah, which are said to have been over 900, or even of Methuselah, of whom Moses says in Genesis, "And all the days of Methuselah were nine hundred and sixty and nine years, and he died."

DISCUSSION.

Dr. Denslow Lewis, Chicago, referred to the time when he was a medical student at the University of Michigan, some twenty-eight years ago, and congratulated the profession and the public on the advances that have been made in medical teaching since that time. The production of such a paper was impossible then; our knowledge had not advanced sufficiently to enable us to make these researches. Dr. Lewis said that all should feel very thankful that physiologic chemistry has taken such strides of late. We can look forward confidently to the future, in the hope that these technical studies will result in vast practical benefit.

DESCRIPTION OF AN ADVANCEMENT SUTURE.

WITH COLLECTIVE SUGGESTIONS REGARDING OPERATIONS ON THE OCULAR MUSCLES.*

MARK D. STEVENSON, M.D.
AKRON, OHIO.

I am a firm believer in conservative surgery and advocate careful operative interference only in suitable cases after all other means, e. g., *the use of proper* lenses, prism exercises, or fusion training, have failed to accomplish the desired results, to wit: cosmetic straightening of the eyes, parallelism of the optic axes, fixation, establishment of binocular single vision, and in phorias, obtaining the normal balance. I do not intend to discuss the many excellent non-operative methods of treating or aiding these cases, but in this paper I presuppose that all of these have failed, and turn in proper cases to operative procedures as a last resort.

I think that an advancement, alone or combined with a tenotomy, is practically always to be preferred to a tenotomy alone. An external ocular muscle is seldom too strong, the rotation of an eye rarely exceeds the normal, but in squint and heterophoria, defective rotation in one or more directions is usually found in one or both eyes. Weak and *not* too strong muscles are usually to be dealt with and an operation that will strengthen a weak muscle so that it can properly functionate is required. If in one of these cases, a certain muscle exceeds the normal in strength and its opponent is normal, a tenotomy alone on the over strong muscle is, of course, good practice, providing the degree of squint or tendency to such, is not of too high a degree. All operations should be modified or elaborated, depending on the results of the tests of the relative powers of the muscles.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

If the defect to be overcome is slight, as in low degrees of squint or heterophoria, an advancement alone may be all that is necessary, but very frequently I think it advisable to tenotomize, partially or completely, the opposing muscle of the same eye. The degree of this tenotomy must vary according to the needs; when only low degrees of squint or tendencies to such are to be overcome, a slight partial tenotomy which I have recommended, only in these cases, may be done, just sufficient to weaken temporarily the strong opposing muscle. This may be accomplished with but slight or no change in the ultimate attachment of the tendon so that the rotating function of the tenotomized muscle will not be interfered with, or at most, but very slightly. If the tendon is not completely severed, Tenon's capsule not opened too freely, and the check ligaments not tampered with, the muscle cannot change its point of attachment much. It will be in a temporarily weakened condition, however, and will not strongly oppose the advanced muscle, which will in the meantime soon become attached. Thus both muscles will heal at the same time and the function of each will be temporarily and partially suspended due to traumatism.

If tenotomy is not performed at the same time as the advancement, there is a high degree of tension of the ocular muscles which tends to loosen the sutures and fresh tendinous attachments and to force the eyeball back into the orbit. The results immediately after the operation may be correct and satisfactory, but before healing takes place, some slipping of the suture is apt to occur, due to the constant tension of the strong opposing muscle, and the final result is sometimes more or less unsatisfactory. When the opposing muscle has been but slightly tenotomized, no such strain is brought to bear on the suture, and the result, after the operation, is much more likely to be a permanent one. If it is necessary to overcorrect in advancement operations, as many authorities state, it simply demonstrates that the suture used or the attachment of the tendon slips; that the operation is not scientific, especially since it would not be possible to know the amount of probable slipping, and hence of overcorrection necessary. If the suture that will shortly be described is properly made, it will not be necessary to overcorrect and the first effect will be final. Under cocain anesthesia the immediate effect should be permanent and correct. Of course good results largely depend on the good judgment of the operator, as these operations cannot be reduced to mathematical accuracy.

Among other tests I always examine the field of rotation of each eye by Stevens' tropometer in order to determine the relative strength of the muscles. I sometimes find that the total or chief weakness in the muscles of the fixing eye, and if, in such cases, the vision of the squinting eye is good and especially if there is hope of binocular vision, I operate on the muscles of the fixing eye.

The suture material should be black braided silk, about No. 8 in size, which has been boiled, dried and then soaked in a warm sterile ointment composed of equal parts of white vaselin and white wax and 0.25 per cent. carbolic acid. After removal from this ointment the suture is stiff and slips readily. The needles should be sharpened and examined with the same care as cataract knives and always kept in a dry place. Except when in use they should be handled only by forceps, never with the fingers, which might cause them to corrode. It is well before the operation to examine the needles under a strong magnifying lens such as a powerful loupe or a +20 D.S. lens, for often the ends will be found bent or forked, which would prevent the needle from passing readily.

My advancement operation is a modified Worth's, the method of suturing, the most important part, being the only essential difference. It is usually done under local anesthesia, except in very small children and exceptionally nervous people. I have performed this operation on children 7 and 8 years old under local anesthesia. If it is to be done on one of the lateral muscles, for example, a long ½ inch curved incision is made vertically through the conjunctiva, the center nearly touching the cornea, the ends curving away from it. Tenon's capsule is next opened, but not so freely as the conjunctiva, the conjunctiva and capsule are pushed well back, the muscle, capsule and conjunctiva are clamped together by advancement forceps, the toothed blade being superficial to the conjunctiva, then the tendon is cut free from the sclera. However, it is easier sometimes to cut the tendon on a strabismus hook, as afterward it can always be seized and held by fixation forceps while the advancement forceps are being adjusted. It is frequently advisable to change the relative position of the conjunctiva, capsule and tendon in the grip of the advancement forceps, pushing the conjunctiva and capsule farther back on the tendon or vice versa. In paralytic and some other cases, it is best to clamp the conjunctiva, capsule and muscle together without changing their relative positions. I have never found any difficulty in recovering possession of the tendon in case it slipped from the advancement forceps. One of two sharp needles on a prepared suture, is next passed from without inward through the conjunctiva, capsule and junction of the upper and middle thirds of the tendon or muscle. The same needle is then passed outward through the upper margin of the tendon or muscle, through the capsule and conjunctiva, then back through all three just behind the first point of entrance, forming a complete loop. It is then carried subconjunctivally almost to the edge of the cornea and stitched deeply through the episcleral tissue into the sclera. The needle on the other end of the suture is similarly used, making a loop on the lower portion of the tendon, capsule and conjunctiva and also making an episcleral and scleral anchorage near the cornea and close to the other suture, then the two sutures are tied in the first part of a surgeon's knot. Sometimes it is sufficient to pass only one needle through the episcleral and scleral tissue, tying the sutures as before. All superfluous tissue should be removed—only sufficient being left to hold the sutures and close the gap when the sutures are tied. If thought advisable, next perform the proper degree of tenotomy on the opposing muscle of the same eye. The to species as well. That the properties of a cell should persist through several generations points to the conclusion that the persistence depends on persistent chemical and physical composition of the cell. Or using the term in the sense of qualities persisting in the descendant cells, heredity may be defined as the persistence of the chemical composition of a cell through several generations of descendants.

The problem becomes more complex when we deal with the higher organisms, because among these are specifically differentiated cells, possessed of varying properties and capabilities. While these properties and capabilities are derived from the ancestor, the problem is much complicated by the necessary inter-relations of the component cells forming the organism. Further, the individual functions and capabilities of the cell are more numerous. The character of the individual depends on his nutrition, the term nutrition signifying in general the chemical and physical composition of the cell in relation to its medium. In the persistence of the chemical cellular endowment in the ancestors we have the cause of the similarity of individuals forming the family, race or species.

Very generally stated, the characteristics of an individual depend on two factors: 1. The individual nutritive capabilities of the component cells. 2. The harmonious action of the various classes of cells. Since the nutrition of a cell is dependent on the bioplasmine molecule, this body must play an essential, if not the only, part in determining heredity.

Concerning the influence of bioplasmine in heredity, we have to consider in the individual the following factors:

As regards the individual cells: 1. The amount of bioplasmine with which the original cells are endowed. 2. The character of the bioplasmine molecule, particularly its facility of dissociation under appropriate stimuli; as regards the organism as a whole, the harmony or lack of harmony of nutritive energy between the variously differentiated cells.

The latter factor determines whether the resultant will be large or small.

Generally, we will look for a maximum resultant in certain functions and a minimum in others. We look for a certain similarity in the successive similar functions in the individual, and these similarities we can group under the head of characteristics.

DESCRIPTION OF AN ADVANCEMENT SUTURE.

WITH COLLECTIVE SUGGESTIONS REGARDING OPERATIONS ON THE OCULAR MUSCLES.*

MARK D. STEVENSON, M.D.
AKRON, OHIO.

I am a firm believer in conservative surgery and advocate careful operative interference only in suitable cases after all other means, e. g., the use of proper lenses, prism exercises, or fusion training, have failed to accomplish the desired results, to wit: cosmetic straightening of the eyes, parallelism of the optic axes, fixation, establishment of binocular single vision, and in phorias, obtaining the normal balance. I do not intend to discuss the many excellent non-operative methods of treating or aiding these cases, but in this paper I presuppose that all of these have failed, and turn in proper cases to operative procedures as a last resort.

I think that an advancement, alone or combined with a tenotomy, is practically always to be preferred to a tenotomy alone. An external ocular muscle is seldom too strong, the rotation of an eye rarely exceeds the normal, but in squint and heterophoria, defective rotation in one or more directions is usually found in one or both eyes. Weak and *not* too strong muscles are usually to be dealt with and an operation that will strengthen a weak muscle so that it can properly functionate is required. If in one of these cases, a certain muscle exceeds the normal in strength and its opponent is normal, a tenotomy alone on the over strong muscle is, of course, good practice, providing the degree of squint or tendency to such, is not of too high a degree. All operations should be modified or elaborated, depending on the results of the tests of the relative powers of the muscles.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

If the defect to be overcome is slight, as in low degrees of squint or heterophoria, an advancement alone may be all that is necessary, but very frequently I think it advisable to tenotomize, partially or completely, the opposing muscle of the same eye. The degree of this tenotomy must vary according to the needs; when only low degrees of squint or tendencies to such are to be overcome, a slight partial tenotomy which I have recommended only in these cases, may be done, just sufficient to weaken temporarily the strong opposing muscle. This may be accomplished with but slight or no change in the ultimate attachment of the tendon so that the rotating function of the tenotomized muscle will not be interfered with, or at most, but very slightly. If the tendon is not completely severed, Tenon's capsule not opened too freely, and the check ligaments not tampered with, the muscle cannot change its point of attachment much. It will be in a temporarily weakened condition, however, and will not strongly oppose the advanced muscle, which will in the meantime soon become attached. Thus both muscles will heal at the same time and the function of each will be temporarily and partially suspended due to traumatism.

If tenotomy is not performed at the same time as the advancement, there is a high degree of tension of the ocular muscles which tends to loosen the sutures and fresh tendinous attachments and to force the eyeball back into the orbit. The results immediately after the operation may be correct and satisfactory, but before healing takes place, some slipping of the suture is apt to occur, due to the constant tension of the strong opposing muscle, and the final result is sometimes more or less unsatisfactory. When the opposing muscle has been but slightly tenotomized, no such strain is brought to bear on the suture, and the result, after the operation, is much more likely to be a permanent one. If it is necessary to overcorrect in advancement operations, as many authorities state, it simply demonstrates that the suture used or the attachment of the tendon slips; that the operation is not scientific, especially since it would not be possible to know the amount of probable slipping, and hence of overcorrection necessary. If the suture that will shortly be described is properly made, it will not be necessary to overcorrect and the first effect will be final. Under cocain anesthesia the immediate effect should be permanent and correct. Of course good results largely depend on the good judgment of the operator, as these operations cannot be reduced to mathematical accuracy.

Among other tests I always examine the field of rotation of each eye by Stevens' tropometer in order to determine the relative strength of the muscles. I sometimes find that the total or chief weakness in the muscles of the fixing eye, and if, in such cases, the vision of the squinting eye is good and especially if there is hope of binocular vision, I operate on the muscles of the fixing eye.

The suture material should be black braided silk, about No. 8 in size, which has been boiled, dried and then soaked in a warm sterile ointment composed of equal parts of white vaselin and white wax and 0.25 per cent. carbolic acid. After removal from this ointment the suture is stiff and slips readily. The needles should be sharpened and examined with the same care as cataract knives and always kept in a dry place. Except when in use they should be handled only by forceps, never with the fingers, which might cause them to corrode. It is well before the operation to examine the needles under a strong magnifying lens such as a powerful loupe or a +20 D.S. lens, for often the ends will be found bent or forked, which would prevent the needle from passing readily.

My advancement operation is a modified Worth's, the method of suturing, the most important part, being the only essential difference. It is usually done under local anesthesia, except in very small children and exceptionally nervous people. I have performed this operation on children 7 and 8 years old under local anesthesia. If it is to be done on one of the lateral muscles, for example, a long ½ inch curved incision is made vertically through the conjunctiva, the center nearly touching the cornea, the ends curving away from it. Tenon's capsule is next opened, but not so freely as the conjunctiva, the conjunctiva and capsule are pushed well back, the muscle, capsule and conjunctiva are clamped together by advancement forceps, the toothed blade being superficial to the conjunctiva, then the tendon is cut free from the sclera. However, it is easier sometimes to cut the tendon on a strabismus hook, as afterward it can always be seized and held by fixation forceps while the advancement forceps are being adjusted. It is frequently advisable to change the relative position of the conjunctiva, capsule and tendon in the grip of the advancement forceps, pushing the conjunctiva and capsule farther back on the tendon or vice versa. In paralytic and some *other* cases, it is best to clamp the conjunctiva, capsule and muscle together without changing their relative positions. I have never found any difficulty in recovering possession of the tendon in case it slipped from the advancement forceps. One of two sharp needles on a prepared suture, is next passed from without inward through the conjunctiva, capsule and junction of the upper and middle thirds of the tendon or muscle. The same needle is then passed outward through the upper margin of the tendon or muscle, through the capsule and conjunctiva, then back through all three just behind the first point of entrance, forming a complete loop. It is then carried subconjunctivally almost to the edge of the cornea and stitched deeply through the episcleral tissue into the sclera. The needle on the other end of the suture is similarly used, making a loop on the lower portion of the tendon, capsule and conjunctiva and also making an episcleral and scleral anchorage near the cornea and close to the other suture, then the two sutures are tied in the first part of a surgeon's knot. Sometimes it is sufficient to pass only one needle through the episcleral and scleral tissue, tying the sutures as before. All superfluous tissue should be removed—only sufficient being left to hold the sutures and close the gap when the sutures are tied. If thought advisable, next perform the proper degree of tenotomy on the opposing muscle of the same eye. The patient is then requested to look steadily at some small distant object and the hand is passed alternately before each eye while the suture is tightened until the eyes cease to move, when the desired rotative effect is secured and the knot is completed. Under general anesthesia only an approximate correction can be expected. In such cases it is often preferable to tie the suture under local anesthesia after the patient has recovered consciousness and the cover test can be used. It is never necessary to suture the conjunctiva on the side of the advancement, but it is sometimes best to do so over the tenotomized muscle.

By this suture, the upper and lower portions of the tendon or muscle are securely held in separate loops, but not strangled, while the circulation in the middle portion is not interrupted although it is also supported by the cross piece of the suture. The more tension put on this suture, the more securely it will grasp the tendon or muscle. Only one knot is necessary, whereas four are required in Worth's operation. Furthermore, the suture can adjust itself as in the pulley operation and cartwheel motion can be influenced by the location of the anchorage into the sclera. It is simple, easier and takes less time to make than most other sutures, and it holds.

I believe that it will hold, not only in the tendon but also in the muscular tissue, especially when fortified by passing it through the conjunctiva and capsule as described. Different authorities estimate the tendon of the external rectus to be about 3.7 mm. long. I have repeatedly placed the suture farther from the insertion of the tendon than its estimated length, hence in the muscular tissue, with perfect results. If Tenon's capsule is pushed well back on the muscle or tendon, it can afford considerable support to the suture and, because of its great elasticity, it will not limit, ultimately, the rotation of the eye to the opposite side. Furthermore, a careful study of the Y shape of the muscle, tendon and check ligament will make clear why an advancement will increase rotation, and not diminish it as a tenotomy does, and also why advancement of capsule forward will not tend to limit the rotation of the eye to the opposite side. I have frequently tested the field of rotation in eyes thus operated on and found it to be as large or even larger than before the operation was performed. The only possible objection to this suture that I can think of, is that in case any portion of its mooring should slip, it would affect the whole suture. However, this accident has never occurred in my practice.

I soon learned that the greater part of the pain in an advancement is caused by the manipulation of the forceps during the insertion of the sutures. Advancement forceps have usually had their blades at an obtuse angle to the handle and this makes it difficult for the operator to tell how the end of the instrument is placed. He is inclined to move the handle in the middle line, thus strongly pulling one side of the muscle or tendon. The long heavy handle on most forceps, when not supported, also acts as a lever, the eyeball or lids serving as a fulcrum, and pulls themuscle, causing pain. My forceps are curved on the flat so that the end of the handle is always supported by the nose or temple, while the middle portion does not rest on the eyeball or lids. The blades are at right angles to the handle, therefore the forceps are easy to manipulate, causing much less pain than the others with which I am familiar.

Cold applications should be made at regular intervals the first day. A monocular bandage with gauze pad is required for about seven days, the eye being irrigated with some mild antiseptic and dressed each day. In the eye not operated on a drop of 1 per cent. atropin sulphate solution should be instilled and it should be covered with a shade for 24 or 48 hours which may be raised when necessary. The sutures are removed at the end of one week. The patient should be cautioned to look straight forward, turning the body and head instead of the eyes for the first few days. If lenses are to be worn, pieces of adhesive plaster may be placed on them so that a narrow vertical clear space may be left through which the patient can see except when the eyes move laterally. He had best remain in a semi-dark room for the first two days and not use the eyes for at least one week.

After the above consideration of this important subject, I decided to address a circular letter to ophthalmic surgeons throughout the United States in order to have their views regarding some of the difficult questions in ocular muscle operations. I wished to learn regarding only those cases where non-operative treatment had failed or was impracticable, fully realizing its importance in the majority of cases.

That this branch of ophthalmic science is not thoroughly understood is clearly demonstrated by the wide diversity of opinions among leading ophthalmologists, and while in some phases of this interesting subject no uniformity of opinions can be found, yet regarding others, it is possible to arrive at certain deductions. Unfortunately I neglected to place the name of the opthalmologists addressed on the question sheet, therefore I am unable to state the authority for many excellent answers, owing to the failure of the writers to sign their answers.

In what percentage of your ocular muscle operations do you prefer an advancement alone and in which cases?

In over eighty replies to this question but twenty seven stated percentages, the average of which was about 15 per cent. As to the cases in which advancement alone is preferred, many replies were received. Several excellent observers advocate its use in low degrees of exotropia and in exophoric cases, the general censensus of opinion being that it is of the greatest benefit in only a low degree of squint or in a tendency to the same. Some state that it is efficient when a simple tenotomy will not correct or has failed to do so or in case of previous overcorrection. Gifford of Omaha states that it should be used in divergent squint where binocular vision may be expected. Todd of Minneapolis advises its use in a large percentage of phorias and in some alternating tropias. Savage says he uses it only rarely and in cases where the stronger muscle is not intrinsically too strong. Among those who seldom, or never do an advancement alone, are Knapp, Thorington, Hubbell, Ellet, Bradfield, Lapsley, King, Roy, Melville Black, Lukens, Minor, Theobald, Snyder, Foster and Woods.

Do you think that a suture will hold in the muscular tissue or only when placed in, through, or against the tendon?

Reber, Posey, Ziegler, Greenwood, Melville Black, Carrow, Hills, and a few others state that a well placed suture should hold in the muscular tissue. Other observers think that it would conditionally. Among those who have the opinion that the suture would not hold in the muscular tissue, but only in the tendon, are Woods, Weeks, Rogers, Veasey, Wescott, Thorington, King, Vail and Holt. Many include either the capsule or conjunctiva or both, as Holmes, Risley, Knapp, Savage, Würdemann, Dodd and Gifford. Culver and Eaton believe it is best against the tendon. Todd and Howe state that there must be a loop, knot or ligation of the muscle or tendon in order that a suture may hold. I think there may be some slipping of the sutures where the capsule and conjunctiva are not included. It is well to remember that the tendon of the external rectus e. g. is but 3.7 mm. long, and since the sutures are often placed farther from the insertion of the tendon than its whole length, they must be in the muscular tissue.

Do you pass your suture through Tenon's capsule to get additional hold and, if the capsule has first been well pushed back on the tendon, do you think it subsequently affects the rotation of the eye to the opposite side?

Eighty-five per cent. of the replies state that the capsule of Tenon and conjunctiva are included with the muscle or tendon in the suture. Tenon's capsule and the conjunctiva are not included in the suture by 6 per cent. of those who answered. Eighty per cent. of these replies indicate that if the capsule is pushed well back on the tendon before introducing the suture, the rotation in the opposite direction will not be affected. Fifteen per cent. express a belief that the rotation will be affected. About 10 per cent. of the observers seem to think that the capsule should not be pushed back on the tendon.

Do you anchor the suture deeply in the sclera? Have any serious complications been caused by so doing? To what do you attribute it if the suture in the sclera gives way?

Sixty per cent. of the ophthalmic surgeons who replied pass the suture deeply in the sclera. About 15 per cent. pass the suture only superficially through the sclera, or even in only the episcleral tissue. Among the former are Reber, Nance, Connor, Culver, Savage, Holmes, Knapp, Greenwood, Donovan, Weeks, Melville Black, Stricker, Ellet, Gifford, Wescott, Vail, Dean and Würdemann. For every man who believes that deep sutures in the sclera cause serious complications, fifteen think they do not. Several did not answer this part of the question. The great majority of observers think that if the suture in the sclera gives way it is because of its not being placed deeply enough in the sclera or in not including enough of it. Suppuration, too small or too large a thread or needle, too much cutting by the needle, careless tying of the suture, too high tension and insufficient strength of the tissues are also mentioned as explanations.

In advancement do you believe in overcorrecting at the time of the operation? a. If a tenotomy has been performed on the opposing muscle of the same eye? b. If such tenotomy has not been performed? What tests, if any, do you make at the time of the operation to learn when the desired amount of effect is obtained?

About 50 per cent. of the observers believe in overcorrecting at the time of the operation; about 30 per cent. do not; the remaining 20 per cent. are conditional. Some would overcorrect in divergence, but not in convergence, particularly if the convergence be in children. About 60 per cent. consider overcorrecting unnecessary if a tenontomy of the opposing muscle has been performed; about 20 per cent. believe in overcorrection in case the opposing muscle has been tenotomized. Among those who believe that overcorrection is necessary if tenotomy has not been performed, and who usually think it is unnecessary to overcorrect if tenotomy has been performed, are Würdemann, Greenwood, Donovan, Weeks, Eaton, Callan, Griffin, Seabrook, Roy and Ayres.

In approximately what percentage of cases of advancement do you tenotomize the opposing muscle of the same eye, making a combined operation? Name your chief reasons for so doing.

Although some strongly advise against tenotomizing the opposing muscle of the same eye together with advancement, a much larger proportion prefer the combined operation, the average percentage being about 76. It is especially advised in cases where the eye is amblyopic and where there is squint of 15 degrees or more. It is said to increase the effect and to relieve the tension on the suture, so that it will not cut through so readily, and the final result will be more nearly like that at the time of the operation. Savage says the stronger muscle needs weakening and the weaker needs strengthening, especially in internal and external squint, and that he never cuts a tendon entirely across. Some of those who advise the combined operations under different conditions are Risley, Connor, Posey, Savage, Baker of Cleveland, Culver, Todd, Ziegler, Würdemann, Woods, Greenwood, Holmes, Weeks, Theobald, Eaton, Melville Black, Stuever, Veasey, Callan, Bradfield, Griffin, Seabrook, Hulen, White, Ellet, Wescott, Crane, Martin, Hubbell, Holt, King, Roy, Lukens, Hale, Starkey and Thorington.

In what percentage do you perform tenotomy alone and in which cases?

The average of the answers gives approximately 38 per cent. A very large number advise tenotomy in cases of heterophória, especially hyperphoria and esophoria, and in low degrees of heterotropia. Some never perform tenotomy, others do it in all cases. Several stated that if the deviation does not exceed 15 degrees, they do tenotomy alone. Several limit it to the above-mentioned cases, where the vision is good with the two eyes; some to cases where there is no hope of binocular vision, and a few where the squinting eye is amblyopic. Weeks prefers tenotomy in squint of low degree where the opposing muscle is of normal power. Ellet uses it in some cases in children where it seems nature, if helped, will cure. Savage recommends it in a very large percentage of heterophorias. De Schweinitz writes that he is more and more convinced that tenotomies are likely to be followed by excessive effects in after years, and that he inclines more to advancements in the place of tenotomies. Stevens and Risley call attention to the fact that the vertically acting muscles are sometimes at fault, when the defect is apparently in the lateral muscles.

What means, if any, do you employ to prevent sinking of the caruncle?

A majority of the answers showed that nothing was done to prevent sinking of the caruncle; several advise free dissection of the conjunctiva from the underlying tissues out under the caruncle and particularly recommend the avoidance of too free incision of the capsule, and also warn against any or too much interference with the check ligaments. Some recommend that the opening in Tenon's capsule and the conjunctiva be very small; others that the opening in the conjunctiva be large, but that it is subsequently sutured. Holt considers it important that the dissection be carried up under the caruncle in order to cut any fibers of muscle going to it.

Do you think a partial tenotomy has any appreciable permanent effect?

Seventy-five per cent. of the answers to this question are negative. Some have not tried the operation, many others believe the effect is but slight. Among those who answer in the affirmative are Savage, Connor, Ziegler, Weeks, Howe, Griffin, Minor, White and Holt. Several, especially Würdemann, Holmes, Risley, Baker of Michigan, Bradfield, Foster, Eaton, Martin, Porter of Chicago, Carrow, Crane and Grove are very emphatic in opposing it, particuarly in so-called true graduated tenotomy.

If any effect is obtained by a partial tenotomy, is it to be ascribed to interference with the check ligaments, stretching or to what?

Connor and Weeks attribute it to weakening of the muscle, Greenwood to a lessened action of the muscle fibers that have been cut, Ziegler to the elongation of the tendinous attachment, Holt to the setting back of the central fibers of the tendon, Ayres to stretching. With a very little experience, I do not believe that a slight graduated tenotomy, where only the central portion of the tendon is cut, has any permanent effect, as I have repeatedly found that even the slightest strands in the peripheral portion of the tendon, or even posterior to the insertion of the tendon, often prevent the eyeball from changing its position in regard to the muscle, before the reattachment of the tendon. Cicatrization plays an important part in the final effect, no doubt making the condition worse, although at first it may have been better. I think that if an effect is obtained it is probably due to stretching of the muscle or tendon, as may be done by a strabismus *hook, the complete severance* of the tendon, or interference with the check ligaments. Of course, the latter two should not be described as a partial tenotomy.

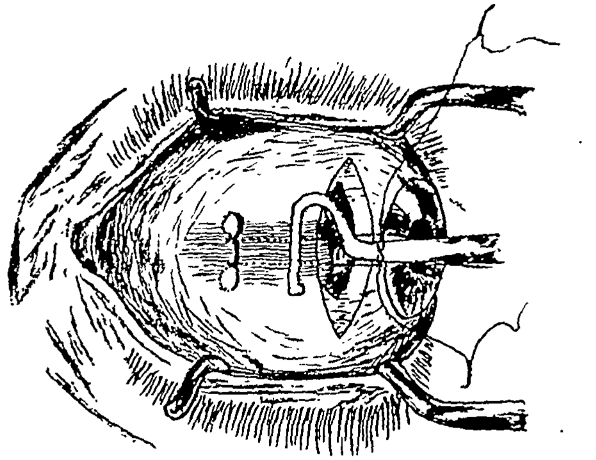

Fig. 1.—Opening in conjunctiva and capsule and position of advancement forceps, suture and knot.

Do you always operate on the squinting eye or are you guided by the degree of rotation of each eye, e. g., as measured by Stevens' tropometer?

A large majority operate only on the squinting eye. Todd, Ziegler, Weeks, Eaton and Hills depend largely on the degree of rotation of each eye. Several always operate on the squinting eye first, especially if it is amblyopic, and later on the other, if necessary.

In approximately what percentage of all your cases do you operate on the fixing eye only? a. If on both eyes separately, why? b. If on both eyes at the same time, why?

The replies show that only a small number operate on the fixing eye alone. Many operate on each eye separately to obtain the desired result, and are guided in the second operation by a knowledge gained of the patient by the first. But very few ever operate on both eyes at the same time, and then only in case the squint is of high degree, or where one eye is very amblyopic, as they fear overcorrection or accident. If the vision in the squinting eye is good and defective rotation is chiefly or wholly found in the fixing eye, and particularly, if binocular single vision is hoped for, I think that the operation should preferably be performed on the fixing eye.

Do you operate when the muscles are paretic or paralytic? What are your indications, choice of operation and results?

Nearly all answer the first part of this question in the affirmative, usually advising advancement combined with tenotomy of opposing muscle of the same eye. Some advised advancement alone. The majority claim good results, especially from a cosmetic standpoint, and several stated that the patient was relieved from the annoyance of turning the head to such a large degree. Many, among whom are Reber, Gifford, Griffin, Ball of Pennsylvania, and Hubbell, advise operative procedures where other means have failed to relieve in one or two years. Stricker of Cincinnati claims excellent results from the use of prisms. He also suggests that as other muscles may subsequently be involved, the cosmetic effect following operation may come to naught. As before stated, I think it advisable, in these cases, to pass the sutures through the muscle or tendon and also through the capsule of Tenon and conjunctiva, without changing their relation to each other.

If the wearing of proper lenses or exercises have corrected the squint and made an apparent cure, is it well ever to operate in an attempt to obtain a better result so that the eyes may be parallel without lenses?

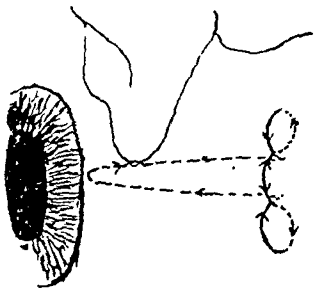

Fig. 2.—Method of inserting suture and location of knot if there is only one point of anchorage in the sclera.

Practically all answer this negatively. Some would operate for the remaining heterophoria present, especially if it is in high degree. Weeks operates where prisms are required, otherwise not.

What do you consider the best age for operation if a child from two to five years old develops squint and the proper lenses (if any are required) and exercises do not correct it? a. If a child has squinted since birth or within a few months of birth—so-called congenital strabismus? Is it a good plan in such cases to make an early approximate correction under general anesthesia?

Among those who consider operation advisable at as early a time as it is found that other means will fail are Holmes, Nance, Savage, Ziegler, Dean, King, Donovan, Dodd, Melville Black, Veasey, Bradfield, Seabrook, Carroll, Hills and Theobald. About 20 per cent. of the observers, among whom are Rogers, Hale, Roy, Baker, Culver, Snyder and Ellet, choose from 5 to 6 years as the best age for operation where good results may be expected. About another 20 per cent. prefer from 7 to 8 years. About 30 per cent. think from 10 to 12 years the best time. Knapp, Hood, Hill and Crane operate as early as the second and third years. A majority of the answers indicates that if the child has squinted since birth, or within a few months from that time, operation should be performed earlier than if the squint had developed later. Others advise waiting until various ages. A large majority of answers show that many do not believe in an approximate correction under general anesthesia, while some claim good results from this in certain cases, especially those of high degree, where other means have absolutely failed. When all means have failed, if the vision and field of rotation are good in each eye, especially if it is possible to develop fusion tendency by the amblyoscope, I think it advisable to obtain an early approximate correction under general anesthesia in order to assist the other factors in producing parallelism of the optic axes. It is well to be very careful not to overcorrect in cases of convergent squint.

In what percentage of your operative strabismic cases is binocular single vision obtained—extreme age limit, if any?

The percentages of success in obtaining binocular single vision vary greatly. Some claim to obtain it in scarcely any, others in a very large proportion of cases. The answers, as a whole, indicate that binocular single vision is often obtained. Several give an age limit from 8 to 10 to 15 years or older. Some cite instances where binocular single vision was obtained in adult life. Greenwood cites the case of a patient 20 years old; Würdemann one of 25; Wells one of 25; Hulen one of 39; Snyder one of 45, and Vail one of 50, each of whom recovered his binocular vision power. Several express the opinion that there is no age limit in these cases, and that binocular single vision might be obtained at any age. Many claimed that their recent increase of successes is the result of experience and the employment of better methods.

In what percentage of your cases do you use a general anesthetic?

A majority prefer the use of local anesthetics, except when advancements are to be performed on small or uncontrollable children or very nervous adults. Several use local anesthesia only when the child's age exceeds 6 to 8 years, as Weeks, Carrow and White. Others choose from 10 to 13 years as the usual age after which it is wise to use local anesthesia. Several never use general anesthetics for tenotomies, but always for advancements.

DISCUSSION.

DR. G. C. SAVAGE, Nashville, said that in treating simple heterophoria the only object is to equalize the tonicity of opposing muscles. In heterophoria of the recti, with cyclophoria, there are two objects in view in the operation; first, to equalize the tonicity of the muscles; second, to change the plane of the muscle. In orthophoria there is absolute rest of the muscles and basal centers, in distant vision, for the tonicity of the muscles is equal. In distant vision these eyes would cross except for the basal centers connected with the externi, and these are the right and left fourth basal centers. Whether the surgeon operates in one way or another, the object must be to equalize the tonicity, and to relieve basal centers. The tonicity may be altered by partial tenotomy, advancement, or shortening. By partial tenotomy of the stronger muscle its tonicity is diminished. By reducing the tonicity of this muscle Dr. Savage has put the fourth basal center at rest. If instead of tenotomizing the internus, it is decided to shorten the externus, its tonicity is thereby increased, making it equal to the stronger one, and thus relieving the fourth basal center. Complete tenotomy, however, should never be done. The LaGlieze operation is far beyond any other advancement operation that has thus far been devised. It is done without severing the tendon, the muscle being made to overlap its original site of attachment. If the knot should become untied the last state of the patient is not worse than the first. It is, too, an easy operation to perform.

DR. WILLIAM C. POSEY, Philadelphia, referred to De Wecker capsular advancement operation as particularly applicable to cases in which there is a divergence of not more than ten degrees. This operation causes not so much reaction as that which follows the advancement of the muscle itself, no such disfigurement and no limitation of rotation of the eye. He has employed it repeatedly, and believes that it is one of the best procedures for the correction of muscular anomalies. He thinks that the single stitch advancement operation, while technically most admirable, is not always to be depended on, as the muscle which demands advancement is so often thin and its tissues delicate, and he invariably employs the double stitch operation.

DR. JOHN E. WEEKS, New York, protested against the use of a stitch that contracts tendon and muscle and bunches them up into a cord; the single stitch does this. When the tendon and muscle are doubled up the reattachment is not a proper one; it takes place at a few points only, at and near the middle of the original insertion. The subsequent contraction of the muscle can not influence the movement of the eyeball as it should. One should select an operation that will spread the muscle out and permit of a broad linear reattachment.

DR. J. A. L. BRADFIELD, La Crosse, Wis., said that in cases of internal squint combined with hypertrophia, operation on the superior or inferior recti usually is of more importance than operation on the internal and external recti muscles.

DR. MARK D. STEVENSON said that the chief objection to the tucking operation advocated by Dr. Savage, lies in the unsightliness of the eye for a long time after the operation. These patients, often operated on for cosmetic purposes, are particularly sensitive just after an operation and do not like the lumpy appearance of the bunched muscle. There is no danger in cutting away the superfluous muscle tissue, which otherwise would take a long time to disappear, as at least an approximately good result may always be obtained. When the capsule and conjunctiva are included with the muscle in the loops of the suture, there can not possibly be much bunching of the muscle. This can be regulated somewhat by the distance between the two points of anchorage in the sclera. If the suture is left in one week, there is formed a broad, strong attachment of the muscle which need never occasion any fear of its slipping. Good scleral anchorage of the suture can nearly always be obtained, but the great difficulty has been to find a suture that would securely hold the tendon or muscle in place until it became reattached to the globe. Sutures that do not have a loop so as to securely grasp the muscle are very liable to cut their way between the fibers. Since there is no means of knowing how much the suture migh slip in such cases, it is impossible to know how much to over correct.

THE VALUE OF VARIOUS FORMS OF HEMOGLOBINOMETERS TO THE GENERAL PRACTITIONER*

M. HOWARD FUSSELL, M.D.,

AND

MARIUS B. MARCELLUS, M.D.,

PHILADELPHIA.

We have undertaken this study because the general practitioner as a rule looks on hemoglobin instruments in general as a sort of medical toy, to be used largely by the consultant, and because we believe that the use of these instruments is practicable and that it does not take more time, nor nearly as much time with some forms, as is wasted over every patient by each of us.

In 1899 one of us read a paper before the Pennsylvania Medical Society in which the following points were noted:

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

1. The necessity of blood instruments becoming part of the equipment of every practitioner.
2. The value of various blood examinations as pointing out the true diagnosis and treatment in many cases.
3. The fact that blood examinations done in a routine manner do not take more time than is constantly wasted in gossip with each patient.

We believe these points were well taken and that they are daily becoming better recognized. In order that we may have certain grounds for the choice of the particular instrument to be used we undertook the study of the Fleischel, the Dare and the Tallquist hemoglobin scale. The Oliver was not studied because the three instruments named above are the most widely used in this country and seem to be all-sufficient. The descriptions of each instrument and directions for their use can be found in all of the text-books on blood technic. and the reader is referred to them for information.

Comparison of Estimates by Different Instruments.

	F.	72	68	65	64

The studies were made mostly in the wards of St. Timothy's Hospital, Roxborough, Philadelphia. Fifty cases were studied with each instrument. Each case was studied at the same time with separate instruments. Recognizing that the personal element could play a part in the reading of any one of the instruments, because a given individual might more readily use one instrument than another, the observations were always made simultaneously by at least two individuals and frequently by three, and the results compared. Dr. Marcellus was used as the basis of comparison in all the cases and his observations are found in each estimate.

In the Tallquist readings the percentage is frequently estimated at 85, that is, between 80 and 90; or 75, between 70 and 80.

In order that an individual might not be prejudiced in the use of any given instrument, the reading was done in the following manner: First the blood was examined by the Fleischel, the scale being covered. Then the Dare instrument was used and the scale was not consulted. Finally, the Tallquist was used. This was done because the scale of the Tallquist is always before the observer. If a known percentage is present, one is very apt to deceive himself in the use of an instrument afterward in the same case. The reading of each instrument was then noted and the results compared.

Differences in the Reading of the Different Instruments When Used by a Single Individual.

Fleischel and Dare: 6 4 2 2 4 2 0 3 2 7 18
0 4 1 2 2 2=61 .... Average 3.3
Fleischel and Tallquist: 8 0 2 1 1 10 30 3 3
2 8 0 3 0 1 3 3=69.
Dare and Tallquist: 2 4 4 1 3 8 30 0 1 5
10 0 1 1 3 1 1=75.
Dare and Gower: 3 6 0 6 3 3 3 7 1 2 1 2
3 0 0 2=40.
Fleischel and Dare: 4 2 6 2 4 4 2 2 4 12 0
0 6 4 2 1 0 2 2=65.
Fleischel and Tallquist: 2 6 8 2 2 0 5 0 4 2
0 0 3 1 5 3 5 4=55................. Average dif.. 3.1
Dare and Tallquist: 2 2 2 2 4 3 2 0 6 0 0
3 3 3 2 5 1=46.
Dare and Gower: 5 2 8=15 .... Average dif.. 3.4
Fleischel and Dare: 4 7 5 3 2 5 1 3 1 1 2
2 6 1=39.
Fleischel and Tallquist: 2 2 0 0 0 0 1 3 2 4
3 1 1 8=27.
Dare and Tallquist: 2 9 3 3 2 5 0 0 1 3 1
3 5 7=44. .... Average dif., 3.3

In the fifty observations made by a single individual the variations seem to be very slight, indeed. If the reading is done with the Fleischel and Dare, the average difference in fifty cases was 3.3 per cent., with Fleischel and Tallquist 3.2 per cent., with Dare and Tallquist 3.3 per cent.

Personal Differences in Readings of Gower, Dare, Fleischel and Tallquist (Marcellus as Standard).

Tallquist: 5 0 0 0 0 5 0 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0 0 5 0 0 0 0 0 0
0 0 0 0 0 0 0 5 5=0.5.
Fleischel: 8 4 4 8 6 4 0 2 8 1 12 4 0 0
2 2 1 0 4 0 4 0 2 2 6 2 5 3 6 4
4 0 0 2 2 4 2 2 2 2 2 2 2 6 2 4
8 4 8 2 4 2 2 6 2 5 3 4 0 4 7 4
Dif. 2,9 per cent.
Dare: 2 2 2 0 2 0 5 2 1 15 0 0 2 2 0 1
2 2 2 6 1 6 1 3 2 0 2 0 2 2 2 0
2 2 2 4 4 2 0 2 2 1 1 1 2 2 0 0
0 0 1 2 2 4 4 0 1 0 2 0 0 0 2...
1.85 per cent.

The personal differences in the use of the different instruments is also seen to be extremely slight. With the Dare the difference was 1.85 per cent, with the Fleischel 2.9 per cent., with the Tallquist 1 per cent. It is fair to state that the Tallquist shows a less percentage of personal differences, because there is no opportunity to judge of less than 5 per cent. difference. The greatest personal differences were with Dare, 15 per cent.; with Tallquist, 10 per cent.; with Fleischel, 8 per cent. The readings of the Tallquist scale were the same in 78 per cent. of the cases, in Fleischel 0.5 per cent., in the Dare 22 per cent. It will therefore be seen that the readings by different individuals is least likely to be just the same with the Fleischel instrument, but, as shown above, the differences are so slight that this is not a fault which interferes with the practical use of the instrument.

It will, therefore, be seen that, so far as practical purposes are, any one of the three instruments is sufficient.

The Dare and the Fleischel allow of more accurate fractional reading because of the arrangement of the scale. All of the scales are accurate.

It appears to us that the advantages of the various instruments may be fairly stated as follows: Of the Tallquist scale, first, the cost is much less, $1.50; secondly, the bulk is less, it may be carried in the inside coat pocket at all times without inconvenience.

The first advantage of the Dare and of the Fleischel is that both can be used either by day or night. The Dare is less bulky than the Fleischel and does not need a particularly darkened room for its use.

The greatest disadvantage of the Tallquist is that one is forced to use it in daylight. The second disadvantage is that an accurate observation can not be made between the multiples of ten, and one therefore feels less sure of the result. The disadvantages of both the Dare and Fleischel are, first, the cost (about $20), and, second, the bulk, though the Dare is less bulky than the Fleischel. In conclusion, we may say:

1. Any one of the instruments studied by us is sufficiently accurate for practical purposes.
2. No practitioner should neglect to use one of these instruments. The Tallquist scale is cheap and convenient.
3. The Tallquist scale can be used for routine observations, and either of the other instruments for detailed and more accurate work.
4. The Dare instrument is just as accurate as the Fleischel, and takes much less time to manipulate.
5. For the general practitioner, the value of these instruments may be fairly arranged as Tallquist, Dare and Fleischel.

A STUDY OF THE METABOLISM OF ATROPHIC INFANTS AND CHILDREN.*

A. H. WENTWORTH, M.D.
Assistant Physician to the Children's Hospital; and to the Thomas Morgan Rotch, Jr., Memorial Hospital for Infants.
BOSTON.

METABOLISM OBSERVATIONS ON INFANTS.

Infant's and children's metabolism has not been thoroughly investigated. The importance of such work has long been recognized, but the difficulties have appeared to be almost insurmountable. Hauser[1] reviewed the work which had been done on this subject up to 1900. In this summary, he called attention to numerous errors in the work and to the incompleteness and inaccuracy of many of the results. Metabolism investigations have little or no value unless continued uninterruptedly for several days. It is essential that the diet should remain unchanged and that the feces and urine should be completely segregated and the entire quantity of each collected during this period.

SOURCES OF ERROR, AVOIDABLE AND UNAVOIDABLE.

The chief difficulty is to collect the entire quantity of feces and urine separately. In most of the reported investigations there was either a direct loss of feces or of urine, or some of the urine escaped into the feces. In some of the earlier investigations the feces were collected on the baby's napkin and afterwards scraped off; this method, of course, resulted in an appreciable loss. In some instances the observations were restricted to one or two days, too short a time to insure accurate results. It was a long time before a satisfactory method was discovered for separating the feces of the metabolism period from the feces which belonged to the periods preceding and following it. Some of the earlier methods for the determination of fat and nitrogen were inaccurate. In some cases the food was not analyzed by the investigator, but analyses were accepted which had been made by other observers. In other cases, the usual diet was quite different from that of the metabolism period and no time was allowed for the organism to become accustomed to the change. In some instances in which the child was on a varied diet, the diet was suddenly restricted in order to reduce the number of analyses; such changes are apt to diminish the appetite and otherwise to affect the metabolism. Sometimes a quantity of food sufficient to last through the observation was prepared and samples of this food selected for analysis. This reduced the number of analyses, but the patient had to eat stale food, which may have influenced metabolism.

In addition to these errors, there still remain some that are unavoidable to a great extent and which alter the results more or less. Of these the following are the most important:

1. The effects produced on the metabolism by restraint and unusual surroundings.
2. Errors due to defects in the methods used to segregate the feces and urine of the metabolism period.

One of the ill effects which has been attributed to restraint and unusual surroundings is, that often during the time in which the metabolism is studied the feces are more watery and are passed more frequently than usual. This effect was not apparent in any of the observations which I am about to describe. In the first case, that of a child four and one-half years old, there was no restraint. Her daily habits and surroundings were unchanged. She remained at home and carried on her accustomed occupations. For the most part she remained in bed because of her condition. A trained nurse who had attended her for more than a year, continued to have the entire charge of her during the observations. This nurse was one whom I had employed many times. She understood perfectly what was required of her and I felt perfect confidence in her reliability.

In the second case, an infant one year old, the effects of restraint were rarely apparent after the first few hours. He played with toys and was happy and contented most of the time. He was always eager for his food and there was no apparent change in the number or character of the dejections with the exception of those which contained the charcoal which was added to the food to segregate the feces. He had not been accustomed to much attention, so that the constant attendance of a nurse was a source of great pleasure to him. I should say that the restraint and changed surroundings produced in his case a minimum amount of disturbance. The nurse in charge of the infant was exceptionally well adapted to the task. She was intelligent, very patient and absolutely trustworthy. During a four days' observation she never left the room for more than a few minutes at a time and she was up many times each night to see that everything was in order. A circumstance of great importance was that both nurses were deeply interested in the work. It is not going too far to say that the success of the work depended on these two nurses.

---

* This work was awarded the Dalton Prize by the Massachusetts General Hospital.

[1] O. Hauser: (references to literature) Die Neueren Arbeiten über den *Stoffwechsel beim Kinde, Speziell beim Säugling* Zeits. f. Diatet. u. physikal. Therapie, vol. iii, 1899,-1900.

In my observations to distinguish the feces of the metabolism period, a weighed quantity of charcoal was added to the food at the beginning of each metabolism observation and to the first food which was given six hours after the close of each observation. Charcoal has a tendency to cause watery movements. To avoid this it should be finely powdered and given in the form of an emulsion and in not too large quantities. Sometimes only a portion of a dejection contains charcoal and the remaining portion looks as usual. It is not only difficult or perhaps impossible in such a case to separate, with absolute accuracy, the feces of the metabolism period from those immediately preceding or following it, but in some cases it is probable that the increased peristalsis, due to the charcoal, hurries a portion of the charcoal through the intestines in advance of the rest. This may become mixed with some of the feces which do not belong to the metabolism period; or if at the end of the period with feces that should be retained, but which in consequence of the presence of charcoal would be discarded. In this way, an error would be introduced that could not be rectified. Chocolate has been used by Bendix[2] and others in place of charcoal. This introduces an appreciable error, unless an equal quantity is reserved for analysis and the results included with the analysis of the food. This necessitates additional determinations of fat and nitrogen. I used chocolate at the beginning of one observation and charcoal at the end. The chocolate contained 0.1978 grm. of nitrogen and 2.6509 grm. of fat. This was equivalent to a little over 1 per cent. of the total nitrogen in the food and to about 2.5 per cent. of the total fat.

The method employed to segregate the urine in metabolism observations in adults can not be employed in similar observations in infants. In the case of adults, no food is taken for twelve or more hours preceding the observation. This is accomplished without inconvenience to the patients by beginning the observation in the early morning. This gives time for the products of metabolism which belong to the period preceding the metabolism observation to become excreted by the kidneys. The urine that is passed first in the morning is therefore discarded. The observation is concluded at the same time in the morning and the first urine passed is retained. Infants are necessarily fed at short intervals and prolonged fasting is therefore impracticable. This difficulty is probably obviated to a great extent by the fact that the infant takes the same quantity and kind of food at regular intervals. If, therefore, the infant's diet has remained unchanged for several days preceding the observation, it is probable that the products of metabolism which are excreted in the urine during a given twenty-four hours would approximate those of a corresponding twenty-four hours. The plan which I adopted was to omit one feeding before beginning the observation, and to begin to collect the urine about one hour after the first feeding was given. At the close of the observation the urine was collected for an hour after the last feeding.

In the case of the first child the diet was unchanged for at least two or three weeks before each observation was begun. In the first observation the diet was arranged primarily to conform to the digestion and appetite of the patient, rather than to furnish a certain number of calories, with a suitable proportion of proteids, fat and carbohydrates. It had been found by observation that certain things were digested better than others, and the diet consisted of these substances.

In the second observation, made a month later, the proteids and carbohydrates were increased and the fat was diminished. These changes were made more than two weeks before the second observation was begun, so that the organism had become accustomed to the changes. In the case of the infant the only change that was made was to increase the quantity of food during the second observation. This change was made at least a week before the second observation was begun.

To determine the quantity of nitrogen and fat that was actually ingested by the infant, the nursing bottle and nipple were rinsed with distilled water after each feeding and the rinsings were reserved for analysis. The nitrogen and fat were determined in the rinsings and the results were deducted from the total nitrogen and fat of the food.

Pepsin was used in the infant's food for both the first and second observations. An equal portion of pepsin was reserved for analysis in each observation. These two portions were mixed together and one set of fat determinations served for both observations. The nitrogen was determined as usual, that is, two determinations for each month. The results were added to those of the food.

A loss of urine or of feces is reported in every published observation on infant's metabolism with which I am familiar. I decided that if any such loss occurred during my investigations I would discard the results. A loss of urine occurred in three investigations not included in this paper, twice on the first day and once at the end of the fourth day. These observations were discarded. In the four metabolism investigations which are here reported there was absolutely no loss of urine or feces.

HISTORY OF CASE 1.

The first case was so interesting clinically that I give a brief account of it. I obtained the following history from the trained nurse who had attended the child for a year and a half previous to the time that I was asked to see her.

History.—Female, aged 4½ years, birth weight nine pounds, normal infant, breast fed until 7 months old. She gained well during this time. At 7 months, she was given barley water and milk, with one feeding of a proprietary food. Later this was increased to several feedings of the same food, with milk. The infant apparently did well and grew very fat. Up to the age of 22 months she had no illness, except influenza at 9 months. At 22 months she began to have indigestion. She was still taking the proprietary food, in addition to her other diet. A prominence of the abdomen was observed at this time. During the next six months she gained but little and her digestion was impaired. At this time, 2 years and 4 months old, she was seen by a specialist, who diagnosed the condition as intestinal indigestion. During the succeeding seven or eight months her weight remained about the same, and once in two or three months she had attacks of acute intestinal disturbance, consisting of fever, diarrhea and rapid loss of weight. During these attacks the food was reduced, and for some time afterward the diet was much restricted. When she was 3 years and 4 months old, she had such an attack, associated with bronchial catarrh. This attack appears to have been severer than any previous one. A slight edema of feet, hands and face was noted for the first time, and later the abdomen became enlarged and measured 25 inches. The quantity of urine in 24

---

2. B. Bendix: Beiträge zum Stoffwechsel des Säuglings, Jahr. f. Kinderheilkunde, vol. xliii, 1896. Weitere Beiträge zum Stoffwechsel des Säuglings. Jahr. f. Kinderheilkunde, vol. xlvi 1898.

hours did not exceed 20 ounces, and at one time was much less. The dejections were loose or watery, with a great deal of mucus in them, and had a very strong odor. This condition lasted for several weeks; then the edema subsided and her weight was found to be 25 pounds. She was at this time 3½ years old. The urine was examined during this attack and a few casts were found. The temperature during the attack was normal. The digestion gradually improved and the dejections became normal in appearance, except that the color was pale. The next attack occurred when she was 3 years and 10 months old. There had been an interval of about three months between these attacks. This attack was not accompanied by edema, it lasted about one week, and she lost 2½ pounds. Just before this attack her weight was 26 pounds, 12 ounces. Two months later (4 years old) she weighed 28 pounds, 4 ounces. The abdomen measured 19 inches. She digested well. A month later she had another attack, not a very bad one, but she was unable to digest solid food and lost one-half pound a week for three weeks. Then edema appeared in face, feet and hands. The amount of urine was 29 ounces in 24 hours. Dejections were watery and contained mucus. The urine diminished in quantity during several days and the abdomen enlarged. The watery dejections increased in number. The urine diminished to 3 ounces on one day and then gradually increased in quantity after hot air baths, etc. The edema was very marked—general anasarca and ascites. Abdominal paracentesis was performed and 18 ounces of clear pale fluid was withdrawn. The temperature was normal during the attack. The urine showed a few hyaline casts. A second examination a few days later showed no albumin, no casts. The abdomen was aspirated a second time, two days later, and about 30 ounces of fluid withdrawn. The daily quantity of urine for about a week did not exceed 9 ounces. After the digestion improved the amount of urine increased to 50 or 60 ounces daily for a few days and the edema disappeared. About one month after the beginning of this attack, she was passing on an average from 40 to 50 ounces of urine each day, and she continued to pass this excessive quantity for several months afterwards. Her weight at this time, after the edema had disappeared, was 25 pounds, 3 ounces, and her age was 4 years and 4 months. In the next three weeks, her weight increased to 27 pounds and her digestion appeared to be as good as at any previous time.

Discussion of Diagnosis.—I saw the child in consultation with Dr. Herman T. Baldwin, of Chestnut Hill, for the first time, at this period. A number of physicians had seen her at different times and had not agreed on a diagnosis. Interstitial nephritis and tubercular peritonitis had been considered among the diagnoses. From the history and physical examination it seemed to me very unlikely that it was tubercular peritonitis, and repeated urine examinations made by Prof. E. S. Wood during the next few weeks failed to detect interstitial nephritis. It appeared to me to be a case of chronic intestinal disturbance similar to infantile atrophy and associated with periodic acute exacerbations of intestinal indigestion. The occurrence of so marked an edema and ascites under such conditions was unusual, and the persistent excretion of such a large daily quantity of urine made me suspect that the kidneys were not normal, although this symptom was present in similar cases that I had seen. I attributed any alterations in the kidneys, if such were present, to the irritative effect produced by the excretion of some substance or substances unknown, which had resulted from prolonged disturbances in metabolism.

Examination.—Physical examination did not show anything abnormal aside from emaciation, a moderate degree of pallor of the skin and visible mucous membranes, and very little edema of the hands and feet. It seemed to me that a study of the child's metabolism might throw light on the nature of the process. It also offered a reasonable hope that, by means of the knowledge thus gained, the diet could be adjusted in such a way as to evert the periodic attacks of intestinal indigestion.

Course of the Disease.—These anticipations were fulfilled, to some extent, by the result of two metabolism observations which were undertaken shortly afterward. The child's digestion steadily improved and she gained in weight during the succeeding five months. At the end of five months she had gained 4½ pounds and weighed 31½ pounds. Her weight at this time exceeded by several pounds that of any previous time, and she had never in the course of her illness had so little digestive disturbance. In May, there was a period of extreme heat, which lasted for ten days, and was responsible for a great many cases of diarrhea and vomiting among infants and children. This child had an attack which lasted several days and left her considerably prostrated. About three weeks after the attack, she was removed to the seashore and appeared to be improving in general condition. A few days afterward, she was taken ill quite suddenly, had a high temperature and a fleeting, patchy erythema which disappeared within a few hours and was not followed by desquamation. The throat was not abnormal and no symptoms appeared which threw any light on the diagnosis. The temperature remained elevated for three days. On the fourth day, the urine became markedly diminished, showed a faint trace of albumin, no sugar, and nothing abnormal in the sediment. The child became stupid and finally unconscious within 24 hours, and the urine was practically suppressed. She was treated energetically with hot air baths and pilocarpin; her bowels were moved freely, and as much water was introduced into her system as possible. She roused somewhat on the following day and recognized her surroundings at times. This improvement only lasted a few hours and then she became unconscious and all treatment was without effect. She died on the sixth day after the acute onset of the disease, with all of the symptoms of uremic intoxication.

Autopsy.—I performed an autopsy about six hours after death. The macroscopic appearances of the organs were not markedly abnormal. Tuberculosis and tubercular peritonitis had been suggested at different times by various physicians, but there was no evidence whatever of tuberculosis anywhere. Microscopically the only abnormalities of any consequence were very marked fatty changes in the renal epithelium, especially of the convoluted tubules. There was no evidence of acute or chronic inflammation in the kidneys. The liver contained an abnormally large quantity of fat, but otherwise was not abnormal. The spleen contained relatively few cellular elements, so that the reticulum was more prominent than usual. Otherwise nothing of consequence was apparent. The lungs and heart and lymph nodes and peritoneum were not abnormal.

METHOD EMPLOYED IN CASE 1.

Two metabolism observations were made on this child. Each observation lasted for four days. The first observation began on Dec. 18, 1902, and ended on Dec. 22, 1902. The weight at the beginning of the first observation was 11,716 grams (25 lbs. 14 ozs.), and at the end was 11,942 grams (26 lbs. 6 ozs.).

The method employed for distinguishing the feces of the metabolism period was the same as that used in similar observations on adults. The observation was begun in the early morning, after twelve hours' abstinence from food. Charcoal was given with the first feeding and the first dejection which contained charcoal was reserved for analysis. At the close of the observation food was withheld for twelve hours, and charcoal was added to the first feeding. The feces were collected for analysis until the charcoal appeared. At the beginning of the observation the first urine passed in the morning was discarded and at the end of the observation it was retained. The weight of the fresh food ingested during the four days' observation was 5,217 grams. The weight of the same food after drying was 908.5 grams. The weight of the dried feces for the same period was 138.79 grams.

The second observation began on Jan. 27, 1903, and ended on Jan. 31, 1903. The weight at the beginning of the second observation was 12,452 grams (27 lbs. 8 oz.), and at the end was 12,791 grams (28 lbs. 4 oz.). The weight of the fresh food ingested during the four days' observation was 6517 grams. The weight of the same food after drying was 1292.5 grams. The weight of the dried feces for the same period was 111.56 grams.

In both metabolism observations on this child, the gain in weight can not be ascribed solely to a new formation of tissue. The presence of a slight amount of edema in the tissues might account for variations of several ounces in the weight. In addition to this, the child was accustomed to receive an injection of water each day in order to obtain satisfactory movements from the bowels. It is possible that some of this water may have been retained in the intestines.

The following method was employed in both observations on this child and the results are arranged for comparison in parallel columns in Tables 1, 2 and 3. The food, both liquid and dry, was weighed each day, in two equal portions, one for the child and one for analysis. When dried substances like rusks or crackers were weighed, each large piece was broken into several smaller pieces and alternate pieces were used for analysis and for the child. Every particle of food was eaten in the presence of the nurse, who was ingenious and devised means to avoid loss of food; viz., butter was spread on the crackers, using a second cracker for a knife; both crackers were eaten; paper napkins were used to collect the crumbs, crumbs were then eaten; glasses containing cream, barley jelly or broth were rinsed with water, which was drunk by the child. The glasses containing liquids or semi-solids, reserved for analysis, were cleansed in the same way as those used by the child, so that the portion for analysis represented accurately the portion actually eaten. The child could always be induced to eat the quantity of food provided for the twenty-four hours, otherwise the work could not have been carried out. The same quantity was not always taken at corresponding meals, but the entire quantity was always consumed in the twenty-four hours.

The food corresponding to that which was eaten by the child each day, was acidulated with hydrochloric acid and evaporated on a steam bath. When almost dry, alcohol was added, and evaporated several times to drive out the water. The dried food was then ground to a fine powder; weighed; mixed thoroughly, and quartered down to a few grams for a single analysis. A similar procedure was adopted for a duplicate analysis. So that each test was made from a quartered sample weighing a few grams.

In my first metabolism observation on this child, I did not appreciate how much difficulty could be caused by the presence of filter paper in the food and feces. It was necessary to cleanse the patient after each dejection and to add the fecal matter thus obtained to the total quantity of feces. A weighed amount of filter paper was used for this purpose and this weight was deducted from the weight of the dried feces and food when computing the quantity of fat and nitrogen. The presence of filter paper in the food and feces made it very difficult to reduce them to a powder. It also introduced an error in the feces which I was only partially able to rectify. It was impossible to mix the powdered feces and filter paper so that each aliquot portion contained the same weight of feces and of filter paper. One sample would contain a little more feces and another would contain more filter paper. Two final determinations of the total fat in the feces showed a difference of about 5 per cent. This introduces an error of 2.5 per cent. This was in a second series of determinations. In the meantime, the feces had been mixed and quartered repeatedly for nitrogen determinations. Filter paper was not used in the subsequent observations. Instead the parts were cleansed by means of a rubber finger cot on the nurse's finger and the fecal matter was washed off the cot into the general receptacle; by this means none was lost.

The feces for each day were evaporated on a steam bath after acidulation with hydrochloric acid. The moist weight could not be determined. At the end of the four days' observation the drying was assisted by evaporating with alcohol several times. The feces afterwards were treated in the same manner as the food, i. e., ground to powder, weighed and quartered to a few grams for each analysis. Up to the time that the food and feces were powdered and weighed, the greatest care was taken that none should be lost. All dishes or apparatus that came in contact with the food or feces, were scraped and then washed with alcohol, the alcohol evaporated and the residue added to the food or feces as the case might be.

The child was accustomed to have enemata and without them the bowels did not move satisfactorily and she was liable to attacks of indigestion. The enemata were continued during the observations.

She was always required to pass urine before receiving an enema; and to avoid any loss of urine at the time of the movement, I arranged a simple device which succeeded perfectly. It consisted of a small tin funnel, which I flattened a little from side to side. A piece of rubber tubing was attached to the outlet and from thence led to a receptacle on the floor. During defecation the funnel was pressed firmly against the labia by means of a stout piece of twisted wire, which had a loop at one end through which the end of the funnel passed.

The urine was preserved with chloroform and made up to a definite volume so that analysis was simplified. The nitrogen was determined in the urine each day by Kjeldahl's method, using sulphuric acid, sulphate of potassium and sulphate of copper. In the case of the food and feces, a weighed portion of the dried substance was used. The urine nitrogen was determined in 5 c.c. of the diluted urine measured in a pipette. The same pipette was used in all determinations.

The fat in the food and feces was determined by the Soxhlet method, using petroleum ether. The petroleum ether was subjected to two distillations and tested for a residue before using. A weighed amount of the dried substance was treated with alcohol containing 2 per cent. of hydrochloric acid and evaporated almost to dryness; alcohol was then added and evaporated several times. When nearly dry, a quantity of sand sufficient thoroughly to separate the particles was stirred in and the mixture evaporated to dryness. The sand was thoroughly washed and ignited for several hours and a blank extraction made before it was used. In all fat determinations continuous extraction was maintained for from 48 to 72 hours. At the end of this time, fresh ether was added, extraction was continued for a time and then the ether was tested for a residue. Finally the ether containing the fat was evaporated and the flask and its contents were placed in a thermostat at 95° C. for several hours. After it was cooled and weighed the procedure was repeated and a second weighing made.

All the fat and nitrogen determinations were done in duplicate. When the results disagreed, a second series of determinations was made.

The method of preparing the food for analysis was devised by McCrudden.[3]. This method was thoroughly tested by him and found to be accurate. McCrudden says:

> This makes but one analysis of the food necessary and permits giving the patient an unrestricted diet. The food given is always fresh, and the inaccuracy due to keeping is overcome by weighing the patient's food and that for analysis at the same time. . . . In quartering, the food is thoroughly mixed with a large spatula and then is made into a little circular pile a couple of inches high. The pile is divided into four nearly equal quarters. Two opposite quarters are rejected and the other two well mixed, made into another little pile and quartered again. The mixing and quartering are repeated until there is about enough food left for one set of analyses. Samples for duplicate and triplicate analysis are obtained in the same way.

The mixing and quartering can be done conveniently on a large plate of glass.

A series of heat determinations were made of the food. These tests were made in Prof. Norton's laboratory at the Massachusetts Institute of Technology. The determinations were made in a modified Berthelot's bomb under the direction and with the assistance of Prof. Norton. I am glad of this opportunity to thank him for his great kindness to me. It was my intention to have determined the heat in the food, feces and urine from each observation, but a satisfactory method for drying the urine without loss of nitrogen was not discovered until too late.

TABLE OF RESULTS IN CASE 1.

TABLE 1.

December, 1902. Nitrogen Determinations. January, 1903.

	Nitrogen in grams.	Nitrogen in grams.		Nitrogen in grams.	Nitrogen in grams.
908 5 grams dried food contained..	....	20.2235	1292.5 grams dried food contained .	. . . .	28.0515
Urine nitrogen,			Urine nitrogen,		
December 19	3.3038		January 28	4.2647	
December 20	3 8671		January 29	4 5212	
December 21	3.4515		January 30	4.5896	
December 22	3 6611		January 31	4 3502	
	14 2835			17.7257	
Feces nitro. (138 79 grams dried wt.)	5.0242		Feces nitro. (111.56 grams dried wt.)	5.9185	
Total nitrogen excreted in feces and urine	19.3077	19.3077	Total nitrogen excreted in feces and urine. . . .	23.6442	23.6442
		+0 9158			+4.4103

Summary.

24.84 per cent. of total nitrogen excreted in feces.
3.62 per cent. dried feces consisted of nitrogen.
15.27 per cent. by weight of dried feces to dried food.

Summary.

21.09 per cent. of total nitrogen excreted in feces.
5 30 per cent. of dried feces consisted of nitrogen.
8.63 per cent. by weight of dried feces to dried food.

ANALYSIS OF RESULTS IN CASE 1.

An analysis of Tables 1, 2 and 3 show certain results. There was almost one-third more fat in the food in December than in January, and a very marked difference in the percentage of fat in the feces in the two observations. In December, 19.05 per cent. of the dried food consisted of fat; in January, 9.95 per cent. consisted of fat. In December, 40.19 per cent. of the fat ingested appeared in the feces; in January, 16.45 per cent appeared in the feces.

Contrary to what one would expect, the excessive quantity of fat in the diet in December and its markedly deficient absorption by the intestines did not appear to interfere very much with the absorption of the nitrogen. A comparison of nitrogen absorption in December and January shows 24.84 per cent. nitrogen excreted in the feces in December and 21.09 per cent. nitrogen excreted in the feces in January. This is quite striking, because it is believed that excessive quantities of fat not only impair the fat digesting and absorbing functions, but also interfere with the other digestive functions. The fat offers a mechanical hindrance to the action of the other ferments on the food and gives rise to abnormal decomposition products. It must be remembered, when comparing the December and January results, that the conditions were dissimilar in these two observations. In December, the child was recovering from a severe digestive disturbance. In January both her general condition and her digestion were considerably improved. The food in January contained very much less fat than in December and was a very much more suitable one in the relative proportions of fat, proteids and carbohydrates. In December, the diet had not been adjusted, but articles had been added that previous experience had shown to agree with the patient.

TABLE 2.

December, 1902. Fat Determinations. January, 1903.

	Weight in grams.		Weight in grams.
908.5 grams of dried food contained.	173 1096	1292.5 grams of dried food contained	128.6741
138.79 grams of dried feces contained	69.5797	111.56 grams of dried feces contained	21.1753

Summary.

40.19 per cent. of ingested fat excreted in feces.
19.05 per cent of the dried food consisted of fat.
50 13 per cent of the dried feces consisted of fat.

Summary.

16.45 per cent. of ingested fat excreted in feces.
9.95 per cent. of the dried food consisted of fat.
18.98 per cent. of the dried feces consisted of fat.

TABLE 3.

December, 1902. Heat Determinations. January, 1903.

1 gram of dried food . . .	temp. rise 2 15°	1 gram of dried food. . .	temp. rise. 1 975°
2 15° rise temperature .	large cal. 5 12	1.975° rise temperature .	large cal. 4.7

Summary.

Calories per diem ingested in food	1162.9	Calories per diem ingested in food	1518.7
Calories per diem excreted in feces	212 2	Calories per diem excreted in feces	144.7
Calories per diem actually absorbed	950.7	Calories per diem actually absorbed	1374 0
Calories per kilo weight per diem in food . .	98.3	Calories per kilo weight per diem in food	120.3
Calories per kilo weight per diem absorbed	80.3	Calories per kilo weight per diem absorbed	108.8
Gain in weight per diem in grams	56.5	Gain in weight per diem in grams	84.75

A consideration of the distribution of the calories in the component parts of the food will show this clearly. The heats of combustion of the total quantity of food taken in the December and in the January observations were accurately determined by means of a bomb-calorimeter. This permits a computation of the distribution of calories in the component parts of the food to be made with sufficient accuracy for purposes of comparison, which is all that is intended. The factor 6.25 was used to determine the amount of proteid material which corresponded to the nitrogen content of the food. This is incorrect for estimating the proteid in cream, but it was not possible to determine the nitrogen separately in the cream. The calories due to carbohydrates are estimated by difference. Table 4 shows the approximate distribution of the calories in the food for a single day in December and in January:

---

[3] American Journal of Medical Sciences, March, 1903.

TABLE—4.

December.	Calories each day.	Approximate wt. in grams.	January.	Calories each day.	Approximate wt. in grams.
Proteid....	129.5	31.5	Proteid....	179.7	43.8
Fat.	402.5	43.2	Fat	299.2	32.1
Carbohydrate.	630.9	153.8	Carbohydrate	1039.8	253.6
Total	1162.9		Total	1518.7	
98.3 Calories per kilo per diem.			120.3 Calories per kilo per diem.		

The weight of the dried feces in December far exceeded the weight of the January feces, notwithstanding that much less food was ingested in December. Thus: December: Weight of dried food, 908.5 grams; of dried feces, 138.79 grams. January: Weight of dried food, 1292.5 grams; of dried feces, 111.56 grams.

This excess in December was due in part to the larger quantity of fat in the food, but the impaired state of the digestion and the general condition in December as compared with January must have exerted some effect on absorption.

In December, 50.13 per cent. of the weight of dried feces was fat; in January, 18.98 per cent. was fat.

Heat determinations of the food and feces in this case show that in December, 1162.9 calories were ingested each day and that 212.2 calories were lost in the feces each day. If one regards the difference as so many calories absolutely absorbed, it leaves 950.7 calories. This corresponds to 80.3 calories per kilo weight a day. Heat determinations of the food and feces in January show that 1518.7 calories were ingested each day and that 144.7 calories were lost in the feces. The difference is 1374 calories, or 108.8 calories per kilo weight a day. This number of calories per kilo is considerably more than is required to maintain the weight of a child of the age of this one. At any rate, in spite of impaired absorption, the child absorbed more than enough to maintain her weight; as a matter of fact, there was a steady gain in weight and improvement in general condition from this time until the following May.

HISTORY OF CASE 2.

The second case is that of an infant one year old, with a history of faulty feeding and chronic gastroenteric disturbance. Physical examination showed very marked emaciation and a moderate degree of anemia. Nothing abnormal was detected in the various organs. The temperature was subnormal during a greater part of the time that the infant remained under observation. Weight 5490 grams (12 lbs. 2 oz.).

METHOD EMPLOYED IN CASE 2.

Two metabolism observations were made on this infant. Each observation lasted four days. The first observation began on Oct. 27, 1903, and ended on Oct. 31, 1903. The weight at the beginning of the first observation was 5955 grams (13 lbs. 2 oz.), and at the end was 6135 grams (13 lbs. 8½ oz.).

The infant received seven feedings in each twenty-four hours. The first feeding of the metabolism period consisted of 75 c.c. of whole milk and 75 c.c. of barley jelly. In order to differentiate the feces of the metabolism period, a few grams of powdered chocolate were dissolved in 70 c.c. of the milk and barley jelly mixture. Thirty-five cubic centimeters of this mixture were added to the 150 c.c. of the first feeding and the remaining 35 c.c. were reserved for analysis. Each subsequent feeding consisted of 100 c.c. of whole milk and 100 c.c. of barley jelly. The food was peptonized for ten minutes before each feeding.

The first dejection occurred at 4:30 p. m., October 27, and contained no chocolate. The second dejection occurred at 2:30 a. m., October 28, and was intimately mixed with chocolate. It was soft, smooth, chocolate brown in color and contained more fluid than normal. Following this, there were three additional dejections on October 28, at 7:30 a. m., 12:30 p. m., and at 3:30 p. m. These dejections contained less fluid than the first one, and the last one contained only a trace of chocolate. The subsequent dejections were yellow in color, of normal consistency and slightly curdled in appearance. There were two dejections daily after the first 24 hours. Three grams of charcoal were given with the first feeding six hours after the first observation was concluded.

The total weight of the dried feces for the four days' observation was 55.7418 grams. The total quantity of food taken during this time was 5550 c.c.

A second metabolism observation on the same infant began on Nov. 13, 1903, and ended on Nov. 17, 1903. The infant's weight at the beginning of the observation was 5825 grams (12 lbs. 14 oz.) and at the end was 6120 grams (13 lbs. 8 oz.).

The infant received seven feedings in each 24 hours. The first feeding of the metabolism period consisted of 100 c.c. of whole milk, 75 c.c. of barley jelly, and 35 c.c. of a mixture composed of 3 grams of willow charcoal suspended in 40 c.c. of mucilage of acacia. Each subsequent feeding consisted of 110 c.c. of whole milk and 110 c.c. of barley jelly. The food was peptonized for ten minutes before each feeding. There were four dejections in the first 24 hours. A small portion of the first dejection was mixed with charcoal. This portion was reserved for analysis and the remainder was discarded. The second dejection was completely blackened with charcoal. The dejections throughout the observation were partly formed and were well digested. After the first 24 hours, they averaged three in number daily. Charcoal was given in the first feeding six hours after the observation was concluded. In the course of the observation, the infant refused 120 c.c. of one feeding. This amount was added to the rinsings for analysis.

The total weight of the dried feces for the four days' observation was 76.4583 grams. The total quantity of food taken during this time was 6115 c.c. The daily quantity of urine passed during both observations was somewhat less than one liter. It averaged about 900 c.c. At the beginning of the second observation, the urine was found to be cloudy when passed. The reaction was acid; there was a trace of albumin present; sugar absent. The sediment was moderately heavy and was composed chiefly of pus corpuscles. A moderate number of caudate cells, corresponding in size to those which line the pelvis of the kidney, were present in the sediment. No casts were found. This pyelitis continued for several weeks. There was never any evidence that the kidney itself was affected. The patient's general condition, appetite and digestion were not noticeably affected and he gained in weight. There was never any edema. The temperature during the first few days was slightly elevated. Previous to this time, the temperature, as in many cases of atrophy, was oftener subnormal than normal. During the early stage of the pyelitis the temperature rose to normal. The cause of the pyelitis could not be determined and the condition would not have been suspected without the urinary examination.

The following method was employed in both observations on the infant, and the results are arranged for comparison in parallel columns in Tables 5, 6 and 7. A method which I devised for segregating and collecting the urine and feces will be described in a future publication.

Throughout the work, the same pipettes were used for measuring fluids. I mixed the food each day and measured the quantity of each feeding directly into the feeding bottles by means of pipettes. A certain quantity of the food was measured into a flask each day and reserved for analysis. A few drops of formalin were added and the mixture was kept on ice until needed for analysis. After each feeding, the nursing bottle and nipple were rinsed with distilled water and the rinsings were reserved for analysis. A few drops of formalin were added to preserve the rinsings.

The urine was collected in glass flasks. The flasks were changed at short intervals and the urine which they contained was poured into a large flask. The small collecting flasks were rinsed each time with a little distilled water. At the end of 24 hours these rinsings were added to the day's urine and the whole was made up to a standard quantity with distilled water. This was done to simplify the nitrogen calculation. The urine was preserved with a little chloroform. Nitrogen determinations in the urine were made each day to avoid any loss of nitrogen from decomposition. The urine was tested for albumin and sugar, and the sediment was examined before and after each observation.

The feces were collected in evaporating dishes and treated as previously described.

The nitrogen was determined in the food, rinsings and urine by Kjeldahl's method, using sulphuric acid, potassium or sodium sulphate, and copper sulphate. For this purpose 5 c.c. of the urine and food were taken for each analysis.

The nitrogen in the feces, pepsin and chocolate was determined in a weighed amount of the dried substance. Fat determinations were made by Soxhlet method. In the case of the milk mixture and rinsings from nursing bottles, 10 c.c. were used for each analysis. This quantity was spread on filter paper that had been extracted with ether previously. This was dried in the thermostat at 95° C. and subjected to 72 hours' continuous extraction. The fat was determined in weighed amounts of the feces, chocolate and pepsin by the method described in connection with the first series of metabolism observations.

ANALYSIS OF RESULTS OF CASE 2.

An analysis of Tables 5, 6 and 7 shows certain results. The composition of the food remained the same in both observations. In the second observation the quantity was increased. In October, the total quantity of food contained 106.72 grams of fat; in November, it contained 119.13 grams of fat. The percentage of fat in the food in October was 1.92 per cent. In November it was 1.95 per cent. Otherwise expressed, each liter

Summary.

15.79 per cent. of total nitrogen excreted in feces.

3.83 per cent. of dried feces consisted of nitrogen.

16.55 per cent. by weight of dried feces to dried food.

* The reason for such a marked apparent difference in the daily quantity of nitrogen excreted by the kidneys in the October observation is that on the first day the urine was collected for twenty-one hours, and on the fourth day for twenty-seven hours. This prevents a comparison of the nitrogen excretion of these two days with that of the other two days of the observation, but it does not alter the total excretion of nitrogen for the four days. It was necessary, in order to arrange my work, to begin the observation at about noon, and in the first observation there was an unavoidable delay of three hours. The only ways by which I could remedy the matter were either to shorten the time of collection of the urine for the first day, or else to postpone the observation. As it did not alter the result I chose the former method.

6115. c.c. of food contained (19.48 grams of fat per liter.)	119.8540
Pepsin contained	0.0915
	119.9455
Rinsings from feeding bottles contained	0.8100
Total fat ingested	119.1355
76.4583 grams of dried feces contained	27.7565

Summary.

23.30 per cent. of ingested fat excreted in feces.

1.95 per cent. of the food consisted of fat.

36.30 per cent. of the dried feces consisted of fat.

of food contained in October 19.22 grams of fat, and in November 19.48 grams of fat. It will be seen that the fat content was approximately the same in both observations. In November, there was a much greater loss of fat in the feces, and the weight of the dried feces was considerably more than in October. The appearance of the feces when passed was not dissimilar in the two experiments and looked much more normal as a rule than is usual in cases of atrophy.

In October, the dried feces weighed 55.74 grams and contained 11.80 per cent. of the fat ingested. In November, the dried feces weighed 76.45 grams and contained 23.30 per cent. of the ingested fat. Notwithstanding the increased quantity of feces in November and double the percentage of fat which they contained as compared with October, the percentage of nitrogen lost in the feces in November was less than in October. In October the feces contained 17.06 per cent. of the nitrogen ingested, and in November, 15.79 per cent.; so that the greater loss of fat in the feces in November did not increase the loss of nitrogen. In both observations, the nitrogen retention was about the same, viz.: October, + 1.9907 grams; November, + 2.0873 grams.

There was no apparent difference in the infant's condition in the two observations. He ate, slept and digested about the same. In the interval between the first and second observations the urine was not examined, but as has been stated, at the beginning of the second observation a pyelitis was found. A little less urine was passed during the second observation than during the first, but the nitrogen excretion was not interfered with. The proportion of urine nitrogen to that of the food was about the same in both observations. In October, the nitrogen excreted in the urine was equivalent to 71.5 per cent. of the nitrogen in the food, and, in November, it was equivalent to 72.95 per cent. of the food nitrogen. So far as the absorption of fat in the two observations was concerned, it was evidently influenced by something besides the percentage of fat in the food. The second observation was as near a control of the first as it was possible to make it. The only difference was 125 c.c. more food each day, without any appreciable difference in its composition. The variation in the fat absorption without any discoverable reason, affords an instance of the impossibility of drawing accurate conclusions from a limited number of observations, even when the observations are very carefully carried through.

The heats of combustion of the total quantity of food taken in the October and in the November observations were accurately determined by means of a bomb-calorimeter. Table 8 gives an approximate estimation of the distribution of calories in the component parts of the food for a single day in each of the two observations. The factor 6.33 was used to convert the nitrogen into its equivalent of proteid. This is somewhat inaccurate because part of the proteid was present in a different form in the barley jelly. The results are sufficiently accurate for a rough comparison, which is all that is intended. The calories due to carbohydrate are estimated by difference.

VARIATIONS IN WEIGHT.

Conclusions derived from a consideration of the variations in weight during a metabolism observation of a few days' duration, are valueless unless the metabolism observation includes a respiration experiment. Without this, it is impossible to say to what a gain or loss of weight is due. In some cases, changes in weight are due to variations in the contents of the bladder and intestines at the beginning and at the end of the observation; in some cases water is retained in the organism. It has been shown by Rubner,[4] Freund[5] and others[6] that considerable quantities of nitrogen may be retained in the organism associated with but slight gain in weight or even with a loss in weight. The proteid gain in weight in such a case is balanced by a loss of fat tissue. Until these facts were appreciated great importance was attached to variations in weight during an observation and many valueless conclusions resulted. Any gain in weight associated with nitrogen retention was ascribed to the formation of new tissue. Table 9 furnishes some interesting information. It will be seen that there was a gradual gain in weight during three and one-half months from 5490 grams to 7220 grams. During this period on several occasions there occurred marked daily variations in weight. These sudden changes could not always be explained by the quantity or character of the food nor by the condition of the digestion. A probable explanation is that variations in the contents of the bladder and intestines caused it.

After the first metabolism observation in October, a night feeding was omitted, and the weight fell; but later, when the night feeding was resumed and in addition the twenty-four hour quantity of food was in-

creased, the weight remained practically the same as during the first observation. The day following the second observation in November, the infant lost 170 grams, although the food remained unchanged. This illustrates what has been said about the valuelessness of conclusions drawn from partial metabolism observations. In all probability the marked apparent gain in weight during each observation was due to something besides the formation of new tissue and fat. Following the second observation the weight remained about the same for two weeks, although the food was strengthened. During the last month additions were made to the diet, namely beef juice, broth and bread, and the gain in weight, whether due to this or not, was steadier and more rapid than at any time previous.

UNWARRANTABLE CONCLUSIONS.

In this connection I wish to add a few words about the tendency to draw conclusions based on uncertain evidence. This is especially evident in metabolism work. It would seem as if the obscurity of the whole subject would restrain any impulse to express one's self positively about causes and results, but to judge from the writings on the subject, it would appear to inspire confidence and an inclination to formulate laws. As has been pointed out, there are many possible sources of error in the work, some of which can not be avoided. In addition to this, the number of observations on infants is limited. The power of absorption and of utilization of the food must vary in different atrophic infants, depending in part on the degree of disturbance present, and especially on the character of the food. It is reasonable to suppose that it varies at different periods in the same infant. Furthermore, with the exception of Rubner's investigations, all the metabolism observations on infants are incomplete, that is, they consist solely of determinations of the fat and nitrogen absorption and excretion. A formation or destruction of tissue can not be determined from such observations. Metabolism observations, however, more especially the complete ones, have established a number of important facts connected with the metabolism of infantile atrophy. They have shown a diminished power of absorption by the intestines for cow's milk and other artificial foods, but they do not explain the cause of this failure to absorb. They also have shown that a greater expenditure of energy is required to metabolize these artificial foods than is required to metabolize human breast milk. Furthermore, enough has been done in this direction to show that the cause or causes of infantile atrophy can not be discovered by metabolism investigations. This must be left to other lines of research.

This work was done in the Pharmacological Laboratory of the Massachusetts General Hospital in 1902-3 and 1903-4. I wish to thank Dr. Franz Pfaff, director of the laboratory, and his assistant, Dr. Vejux-Tyrode, for valuable advice and assistance. I am especially indebted to Mr. F. H. McCrudden for careful instruction in the methods which are employed in metabolism work.

Radium of Little Use in Skin Diseases.—Danlos concludes from his personal observations (*Bull. et Memoires de la Soc. Med. des Hôpitaux*) that there are only three skin disorders in which radium has a real value—tuberculous lupus, pearly epithelioma and vascular nevus. *Even in these its therapeutic value is a limited one. We have other older and more* effective remedies, the *x*-ray for example. *We may admit for* it some advantages for use in the larynx and nasal fossæ, especially if its cost is reduced.

THE PATHOLOGIC EFFECTS OF ALCOHOL ON RABBITS.

AN EXPERIMENTAL STUDY.*

JULIUS FRIEDENWALD, M.D.
BALTIMORE.

VARIETY OF ALCOHOL USED AND METHOD OF FEEDING THE ANIMALS.

One hundred and twenty rabbits were utilized in the experiments with alcohol. Most of these animals were fed on absolute alcohol diluted; some on an inferior form of whisky known as "Calumet," 70, proof 33.6 per cent. In order to be certain of the exact dosage, the alcohol and whisky were introduced into the stomach through a catheter. The catheter is easily introduced into the stomach of a rabbit; the animal is placed flat on its back and strapped to an animal board; the ears are then firmly grasped, the mouth opened by means of a large forceps and the tube forced into the stomach. By means of a funnel attached to the end of the catheter, the liquid quickly enters the stomach; with practice the introduction of the tube becomes a matter of great ease and one need not fear in any way injuring the esophagus or entering the trachea and thus producing an aspiration pneumonia. After the practice of a month all complications were avoided and in none of the autopsies could any injury be discovered in the esophagus or was there any evidence of an aspiration pneumonia.

TIME TAKEN TO PRODUCE INTOXICATION AND RECOVERY.

In from 5 to 15 minutes after feeding, the animal shows signs of intoxication, the movements become sluggish and unsteady and when urged on he is unable to move. This intoxication passes on into a complete stupor from which the animal cannot be aroused. It awakens in from 3 to 5 hours and appears well on the following day. From an average drawn from all the histories, it can be stated that intoxication begins 14 minutes after feeding, complete intoxication 32 minutes after feeding, and that the intoxication disappears in 3 hours and 5 minutes from the time of feeding. These conditions vary much with the dosage, weight of the animals and apparently individual peculiarities (species). In general it can be stated that the quicker the intoxication comes on the more rapidly does the influence of the alcohol pass off.

QUANTITY OF ALCOHOL ADMINISTERED.

The quantity of alcohol taken by the rabbits varied very much according to the size and strength of the animal, and according to the duration of its life. On account of a sudden loss of weight or apparent illness the doses at times had to be discontinued for days until the animal was again in a normal condition. The daily doses varied between 5 and 8 c.c. of absolute alcohol diluted in from 15 to 30 c.c. of water, or 10 to 20 c.c. of whisky diluted in 10 or 20 c.c. of water. The average of the weekly doses in various rabbits varied very much; thus, while one rabbit consumed a weekly average dose of 40 c.c. of absolute alcohol, another consumed 48 c.c.; and, again, while another rabbit consumed a weekly average dose of 96 c.c. of whisky, another consumed 110 c.c.

The smallest weekly dose of alcohol taken was 20 c.c., the largest 50 c.c.; the smallest weekly dose of whisky 94 c.c., the largest 136 c.c. Of greater interest is the total quantity of alcohol and whisky taken by the animals. The animal that lived longest consumed over 10 liters of absolute alcohol, another rabbit consumed 7.5 liters, while another consumed over 18 liters of whisky.

VARIATIONS IN WEIGHT.

Most animals gain in weight for a time at first; the weight then remains stationary and there is a rapid fall in weight when the animal is about to die. Rapid emaciation always signifies approaching death. When there is a loss in weight during the first month one can predict an early death. The daily variations in weight during the first month show an average gain of from 5 to 8 grams; during the second month from 10 to 20 grams; during the remaining months there is practically a stationary weight, and during the last month a marked fall averaging from 10 to 20 grams.

The monthly variations in weight taken as an average from all animals was 12.5 grams.

VARIATIONS IN TEMPERATURE.

The temperature falls from 0.1 to 0.5 degrees when the intoxication begins and from 1 to 1.5 degrees when complete intoxication sets in; then gradually rises and is normal the next day.

From the average of all the rabbits the normal temperature is 104 F.; the average temperature at the beginning of intoxication, 103.8; in complete intoxication, 102.9; when the temperature falls below 102 F. the animal dies from the immediate effect of the alcohol without regaining consciousness.

BLOOD EXAMINATIONS.

A large number of blood examinations were made; these examinations consisted in the counting of the number of red and white blood cells by means of the Zeiss-Thoma apparatus; estimation of the hemoglobin by means of the Fleischel apparatus; also staining dried spreads with Ehrlich's triple stain. It was found that while the number of red and white cells are not diminished in any case except when the animal was about to die the percentage of hemoglobin sinks rapidly after the first week and gradually runs to half its normal.

The number of red blood corpuscles in a normal rabbit varies between five and six millions in a c.mm. The number of leucocytes varies between 5,800 and 14,000, the average being 10,000. This average was found to be maintained under the influence of alcohol until the last month of feeding, when the red cells fell as low as two million and the white cells as low as 5,100. The percentage of hemoglobin in the normal rabbit before feeding varies between 80 and 90 per cent. during the first month of feeding with alcohol the average fall is to 75 per cent., during the middle month of feeding 62 per cent., and during the last month of feeding 45 per cent.

The blood spreads show in the rabbit under normal conditions the following relations: Small lymphocytes, 45 per cent.; large mononuclear, 15 per cent.; eosinophiles, 32 per cent.; undetermined, 8 per cent.

This relation is pretty nearly maintained during the feeding of the animal with alcohol except during the last month of its life, when the following percentage is found: Small lymphocytes, 48 per cent.; large mononuclear, 10 per cent.; eosinophiles, 40 per cent.; undetermined, 2 per cent.

The eosinophiles, which to a great degree represent the polymorphonuclear cells in the human being, being largely increased in number.

---

* From the Pathological Laboratory of the Johns Hopkins University and Hospital.

EFFECT OF ALCOHOL ON THE GASTRIC CONTENTS.

The gastric contents were examined in a large proportion of animals; free hydrochloric acid, which was present at first, gradually became lessened in quantity and often disappeared. At the beginning of feeding with alcohol the average percentage of free hydrochloric acid equaled 0.345 per cent.; this was frequently lessened in the course of one month to 0.213 per cent., and in the course of two months to .003 per cent.

EFFECT OF ALCOHOL ON THE URINE.

The urine was frequently examined in a certain number of animals. At the beginning of treatment, neither albumin nor casts could be found in any urine. Of the specimens of urine examined in 21 animals, 7 showed constantly marked traces of albumin after two months' treatment with alcohol and two slight traces, while casts were found in 5 instances. Specimens of urine from 3 other animals showed occasional traces of albumin. Of the 5 cases in which albumin and casts were found, kidney lesions were detected after death, as will be shown in the pathologic report. It must be stated, however, that notwithstanding the absence of albumin and casts in certain other cases, changes in the kidneys were detected at the autopsy.

EFFECT OF ALCOHOL ON FEMALE RABBITS.

There can be no question but that alcohol has a marked tendency to produce abortion in rabbits. In a series of 38 pregnant rabbits, 20 died of septicemia due to abortion. The organism of rabbit septicemia was found in all cases. The animals had been entirely isolated from each other. Of the remainder, 9 had constant abortions, none of the young being born at full term. Three had their young normally, but these all died in a few days after birth.

EFFECT OF ALCOHOL ON DURATION OF LIFE.

While the tolerance of any given animal could not be positively foretold, young rabbits, pregnant females, and those weighing under one thousand grams were the most susceptible. Certain rabbits were found to be so resistant that they seemed capable of tolerating daily intoxicating doses of alcohol for an indefinite period. Thus, one rabbit was given alcohol for over four years; others were fed with alcohol for three and a half and for three years. These animals had the best of care and were kept under excellent sanitary conditions. On the other hand, some of the rabbits died from acute intoxication after a few doses, and the majority succumbed after shorter or longer periods of time, with gradual loss of weight and exhaustion. If especial care was taken to lessen or to intermit the dose of alcohol when the animal began to lose weight, it was found possible later to increase the dose and to keep a considerable number of the rabbits alive for an indefinite period.

CAUSES OF DEATH AND PATHOLOGIC LESIONS.

The causes of death in the animals varied; many died during the first days or months of feeding of acute intoxication, others died in convulsions, still others of progressive emaciation or septicemia, while one animal died directly from dropsy due to a marked cirrhosis of the liver.

Complete autopsies were made on all animals; specimens were taken from all organs and hardened in absolute alcohol, Müller's fluid and Zenker's solution, and side by side with each specimen were placed the specimens from a normal rabbit; so that a comparison of sections after cutting could easily be made.

In order to simplify the work, the lesions found in the various organs will be taken up separately.

Heart.—The heart muscle showed in the great proportion of those rabbits which died a marked degree of fatty infiltration which was absent in the rabbits which were killed after cessation of the use of alcohol, showing that the fatty degeneration is not a permanent condition even though it be produced by the action of the alcohol.

This fat was diffuse and finely granular. As is well known, rabbits are apt to develop fatty degeneration of the heart muscle when kept in captivity; but it was found that rabbits fed on alcohol develop this condition of the heart much more markedly than the control animals not fed on alcohol. In order to settle this matter more definitely, 10 rabbits were kept in the open air; five of these were fed on alcohol; in 4 of the 5, marked fatty degeneration of the heart muscle developed in from two to three months, while the heart muscles of those not fed on alcohol remained perfectly normal. There can be no question but that in most animals fed on alcohol, fatty degeneration of the heart muscle is often a very frequent early manifestation. After the third or fourth month of feeding with alcohol, a sclerotic or atheromatous patch was now and then found on the inner surface of the aorta or of other blood vessels. The aorta showed here and there small yellowish areas which on microscopic examination revealed a connective tissue thickening in the subendothelial layer of the vessel. The muscular coat showed occasionally a rather marked fatty degeneration as indicated by a deposit of fatty granules in this layer. The same changes were occasionally found in the smaller vessels, though not usually, so marked. These lesions were present, however, too inconstantly to be attributed with any certainty to the action of alcohol, especially as similar lesions are occasionally found in animals which have not received alcohol.

Liver.—The liver, in a few instances, showed a rather coarse lobular aspect; the edge showing a notched appearance as if notched along the interlobular lines. On microscopic examination there appeared in these instances a marked deposition of fine and coarse oil drops in the liver cells; quite diffuse and abundant; bands of connective tissue were found running along the interlobular lines, containing occasionally an increase in lymphoid cells. These bands were richly infiltrated with fine molecular fat. Similar fine fatty granules were in the hepatic cells, especially along their borders, apparently in the capillary walls. There were some oval pigmented cells at times in the bands of interlobular tissue; there was present occasionally a monolobular cirrhosis. Necrosis of the liver cells occasionally occurred, either singly [illegible] At times the blood vessels were found [illegible] tunica adventitia. In many instances, the liver was perfectly normal; in four instances, the liver was found somewhat cirrhotic, and in one instance markedly so, abdominal dropsy accompanying the cirrhosis.

Genuine cirrhosis has not been satisfactorily reproduced in the experiments which lends support, as Welch points out, to the opinion held by many that in human beings alcohol acts only indirectly in leading to cirrhosis of the liver, or that special predisposing or associated

conditions must be present in addition to the action of the alcohol. This failure to produce cirrhosis of the liver experimentally by the use of alcohol can not be attributed in our series to the too short duration of the experiments.

Lungs.—The lungs showed nothing important; frequently in the act of dying edema set in.

Kidneys.—The kidneys showed, as a rule, fine fatty degeneration of the epithelium in the tubules of the boundary zone of the pyramids; also a small amount of deposit in the cortical tubules. Here and there the arteries of the kidneys stood out prominently and on section were found thickened in the tunica adventitia; in a few cases the changes in the glomeruli were marked, a considerable number of these having undergone atrophy. In the five instances in which albumin and casts were found in the urine, these changes in the kidneys were marked. A number of the rabbits showed no changes in the kidneys whatever; an actual chronic interstitial nephritis was never produced.

Stomach and Intestines.—The examination of the stomach showed a round ulcer in two animals and cicatrices of healed ulcers in four. The ulcers were sharply defined, 2 cm. and 3 cm. in diameter, with thickened edges and base—the base being defined by the muscularis. Most frequently the mucus membrane was congested and there was an increase in mucus.

In many instances, the cells of the gastric tubules were cloudy and infiltrated with fatty granules, the interglandular tissue was infiltrated with small round cells and an increase in connective tissue was occasionally observed. There was evidence that some of these alterations, especially the more profound ones, were attributable sometimes to mechanical injuries inflicted by the stomach tube. In many other instances the stomach was perfectly normal. As a rule no pathologic changes were present in the intestine.

Generative Organs.—The testicles frequently showed a diffuse fine deposition of fatty granules scattered in the epithelium of the tubes and interstitial cells. The uterus revealed nothing abnormal except in those cases in which there had been abortions and in which the rabbit had died of septicemia. The uterus, in these instances, was enlarged, and the mucus membrane much infiltrated with leucocytes; the blood vessels were engorged throughout; in every instance the organism of rabbit septicemia was recovered.

Nervous System.—The cortex of the brains of a number of the rabbits was studied by Berkley.[1] The following is taken from his work, "Pathologic Histology of the Rabbit's Cortex in Chronic Alcoholism as Seen with Nissl's Stain," and "Pathologic Histology of the Rabbit's Cortex in Chronic Alcoholism as Seen with the Silver Phospho-Molybdate Stain:"

The smallest arteries have an altogether different appearance from the control preparations. The walls of many of them are irregularly shrunken, at intervals almost botryoidal in appearance; and the nuclei of the vascular walls, while not increased in numbers, are swollen, and project considerably into the lumen of the canal. The perivascular space is larger than in the control preparations, and the hyaline membrane separating it from the cerebral substance is a little more definite than normal. On transverse section the walls of the vessel are a little thickened, the lumen narrowed, the change affecting the intima more than the media. Very few of the arteries show any very pronounced changes. Four or five miliary hemorrhages into the sheaths of small vessels were noted in the several sections, all near the pial margin. Altogether no very definite lesions could be determined in the blood-vessels. Alterations of the nuclei chiefly in the disposition, swelling, and irregularity of contour of the nucleolar chromophilic particles are found.

After all possible allowances have been made for artefacts and for physiologic variations from the normal, as well as for inequalities in the staining process, there remain a large number of cells in our alcoholic brains that are distinctly abnormal. The principal lesions in them, are a distinct diminution in size, a shrinkage of a vast majority of all the cortical cells, particularly in the outspread of the branches, certain swellings of the dendritic processes with disappearance of the gemmulæ, and roughening of the stronger processes, and to a less extent of the cell body. A careful comparison of a control preparation, and one from an alcoholic rabbit's brain, will show the following differences: The cell bodies and main processes in the normal are smoother and more even, the dendrites are broader, the gemmulæ are more even, thicker and feathery, they apparently spread out over more lateral surface, and are very regular in appearance; while in the alcoholic there is a gap here and there as if some of them had fallen off and disappeared. Indeed, the differences between the two cells may shortly be expressed in that the whole appearance of the normal cell is stouter than its pathologic fellow.

SUMMARY OF THE PATHOLOGIC CHANGES IN EXPERIMENTAL ALCOHOLISM.

Prof. Welch[2] has summarized these changes as follows:

1. Animals exhibit marked individual differences in their susceptibility to the injurious effects of the prolonged administration of intoxicating doses of alcohol. While certain individuals succumb quickly, others may be kept alive under these circumstances for at least

---

[1] Johns Hopkins Hospital Reports, vol. vi, No. 1.

[2] "Physiological Aspects of the Liquor Problem."

four years without presenting any serious anatomic lesions attributable to the alcohol. Between the extremes, there are all gradations in susceptibility, young animals and pregnant ones being generally the most susceptible.

2. The experimental reproduction in animals of certain of the more characteristic diseases of human beings, attributable to the abuse of alcohol, such as cirrhosis of the liver, chronic Bright's disease and arteriosclerosis, has not been satisfactorily attained. The most common pathologic condition noted is a fatty metamorphosis affecting especially the cells of the liver, the heart muscle, and the kidneys. This lesion soon disappears after stopping the use of the alcohol. Death or necrosis of limited groups of cells in the liver and kidneys may occur, but is inconstant. More common is an acute or chronic catarrhal gastritis, but this, too, is often absent or but slight. Changes in the central nervous system, similar to those in acute alcoholism, as well as certain additional ones, may be present in experimental chronic alcoholism. Hyperemia and small hemorrhages may occur, especially in the stomach, the kidneys and the brain. In view of considerable differences in the results reported by different experimenters, and of many still unsolved problems, additional experiments on the pathologic effects of the long-continued use of alcohol and of alcoholic drinks are needed.

3. Alcoholic intoxication increases the susceptibility of animals to many infections, and influences unfavorably the process of immunization. Pregnant rabbits repeatedly intoxicated by alcohol are likely to abort, and to die soon afterward from some accidental infection. Many of their young die a few days after birth.

In conclusion, I wish especially to thank Prof. William H. Welch, who directed this work, for his many suggestions and his encouragement in the performance of these experiments.

This work was aided by a grant from the "Committee of Fifty."

PULMONARY STREPTOTHRICOSIS.

A REPORT OF TWO CASES AND A REVIEW OF THOSE HITHERTO REPORTED FROM A CLINICAL STANDPOINT.

THOMAS G. ASHTON, M.D.
Adjunct Professor of Medicine at the University of Pennsylvania; Visiting Physician to the Philadelphia General Hospital.
AND
GEORGE WILLIAM NORRIS, A.B., M.D.
Assistant Visiting Physician to the Philadelphia General Hospital, Physician to the Phipps' Institute and the Out-patient Department of the Episcopal Hospital.
PHILADELPHIA.

It is not our intention in the present paper to discuss the morphology or the classification of the streptothrix. This subject has been very ably considered in the papers of Norris and Larkin,[1] Flexner,[2] Warthin and Olney[3] and others. It may be said, however, that no definite conclusions have been reached. The consensus of opinion seems to be that there are several distinct varieties of steptothrix, and that the various cases reported as instances of streptothricosis have been due to different varieties of this micro-organism.

From a study of the thus far reported cases of pulmonary streptothricosis it seems that the majority of the cases present the clinical picture of pulmonary tuberculosis. Bronchiectasis is frequently encountered, and hemorrhage is quite a common symptom. The majority of cases ended fatally, often as the result of metastasis to different parts of the body, the central nervous system being frequently involved. We have collected only those cases of streptothricosis which showed evidences of pulmonary involvement; numerous cases are on record in which other organs were the seat of the morbid process. Thus, for example, Ucke has reported a case of tonsillitis due to the streptococcus. Of course, it is not proved that this micro-organism was primarily etiologic in all the cases here collected, although in the majority it would seem eminently probable.

The streptothrix belongs to a rather ill-defined class of vegetable micro-organisms which, while in many respects closely simulating bacteria, yet possess certain features resembling the hyphomycetes. The dividing line between the streptothrix and bacteria is hard to draw, inasmuch as some of the latter, such as the *B. diphtheriæ* and the *B. tuberculosis,* at times exhibit branching and other characteristics of the former. Flexner says that the streptothrices, like the moulds, develop from spores into "cylindrical, dichotomously-branching threads, which alternately grow into colonies, the appearance of which suggest a mass of radiating filaments (mycelia)." The streptothrix, then, stands in a class between the moulds and the bacteria.

Doubtless one reason why streptothricosis of the lung has not been reported more frequently is that it is not readily demonstrable by the carbol-fuchsin method of staining, and, therefore, unless the sputum is examined by the Weigert-Gram method the organism may be overlooked. In a number of the cases which we have collected, the sputum was examined repeatedly for tubercle bacilli by the usual carbol-fuchsin method, with negative results, and it was only when the Gram process was employed that the micro-organism was found. The obvious conclusion is, of course, that all cases of suspected tuberculosis in which the tubercle bacillus is not found should be carefully examined by the Gram process *for streptothrix.*

The mere presence of the streptothrix in the sputum or in the tissues does, of course, not prove it to have been the primary pathogenic factor; it may be there simply as a secondary infection; that there are cases on record, however, in which this organism played the main and probably sole rôle in the production of organic lesions, we think, has been incontestably shown. It is a well-known fact that the tubercle bacillus tends to produce different pathologic changes, which present different clinical pictures when it is associated with varying micro-organisms, and it is quite probable that similar variations occur in streptothricosis when mixed infections exist. From a study of the reported cases, it seems that in the acute, bronchopneumonic type of streptothricosis, metastasis is quite common. The skin and the brain seem to be the most frequent locations for such processes, but the bones, the peritoneum, the pericardium, the liver, the spleen, the kidney and the bladder at times have also shared in the involvement. Animal inoculations were made in several cases, and in quite a number typical, although not always fatal, lesions were produced. The tendency to metastasis was also well marked in most of the inoculated animals.

Mayer,[4] in his *"Briefe aus Ostasien,"* mentions having seen ten cases of streptothricosis of the respiratory tract.

The organism was found in the sputum in small yellowish lumps resembling actinomycosis granules; elastic tissue blood and alveolar cells were also present. One case which came to autopsy showed encapsulated gangrenous areas in the right upper lobe of the lung, in which, as also in the pleural cavity, streptothrix could be demonstrated. These cases, occurring, as they did, after a sandstorm, suggested that infection occurred by inhalation. Another case is also mentioned in which apparently well-marked cavity formation healed completely, together with a disappearance of all symptoms.

Streptothricosis of the lung occurs in two forms: 1. The acute variety, which presents the symptoms of bronchopneumonia, with mucopurulent expectoration, yellowish or greenish in color, at times hemorrhagic or containing elastic tissue and bespeaking a necrotic process. Later in the course of the disease we may encounter purulent metastases in other parts of the body. Such have been reported in the skin by Scheele and Petruschky,[5] and in the liver, spleen, heart and brain by Engelhardt and Löhlein.[6] This form, therefore, presents in the advanced stages the clinical picture of a pyemia and seems to run to an inevitably fatal termination.

The gross pathology of the lungs resembles, to a certain extent, that of tuberculosis, with caseous areas and softening, surrounded by zones of round-cell infiltration or induration; occasionally multiple abscesses are encountered.

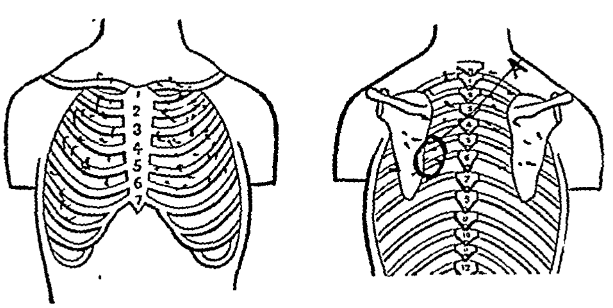

Fig. 1—Showing râles throughout chest. A. Amphoric whispered pectoral râles.

Microscopically, the streptothrix appears as long, fine, homogeneous, glistening threads, occurring in clumps and exhibiting a true branching, staining poorly and especially irregularly with Gram's stain, and thus, too, on superficial examination, resembling cocci (Fraenkel).[7]

2. The chronic variety, first described by Flexner[2] in 1897, presents almost an identical picture with chronic pulmonary tuberculosis. The case here reported showed in the lungs extensive areas of consolidation and necrosis, together with numerous tubercle-like bodies, the latter being also found in the peritoneal cavity.

CASE 1.—W. S., mulatto, aged 22, was admitted to the Philadelphia General Hospital Sept. 7, 1904, on account of inguinal buboes of several weeks' duration, which were the sequelæ of gonorrhea. After undergoing the operations of circumcision and extirpation of the inguinal glands, the patient having a cough and signs of pulmonary apical disease, was transferred to the medical wards.

History.—Father died of unknown cause, mother of pulmonary tuberculosis. There is no history of malignancy or of syphilis. Patient had convulsions in childhood; later measles and diphtheria. He had chancroid of the penis fourteen months ago. He uses alcohol in moderation, but does not use tobacco.

Present Illness.—On admission to the medical wards, the patient complained of persistent cough, with copious fetid expectoration, and of pain in the left side and back.

Examination.—Pulse 90, respirations 35, temperature 102 F. Dyspnea was marked.

Lungs: There was marked dullness of the left chest, extending from the base up to the seventh rib. There was impairment of resonance at the left apex, anteriorly, at which area a few subcrepitant râles were heard. Posteriorly there was dullness at the left apex, with bronchovesicular expiration and great numbers of mixed râles. Over both bases, anteriorly, laterally and posteriorly, resonance and fremitus were diminished, breath sounds were feeble and distant. Posteriorly, beneath the lower third of the left scapula, there was an area of about two and one-half inches in diameter, over which amphoric respiration, ægophony, whispered pectoriloquy and moist resonating râles were heard. The entire left chest was tender on percussion, and respiratory motion was restricted.

Heart: There was marked accentuation of the second sounds at the bases; otherwise examination was negative. Other organs showed nothing abnormal.

Urine: Urine was amber colored, acid, sp. gr., 1024. There was a trace of albumin, no glucose; there were hyaline casts and epithelial débris. It was deficient in amount.

Blood: On several different occasions, this showed a leucocytosis ranging from 9,000 to 13,600, chiefly of the polymorphonuclear variety.

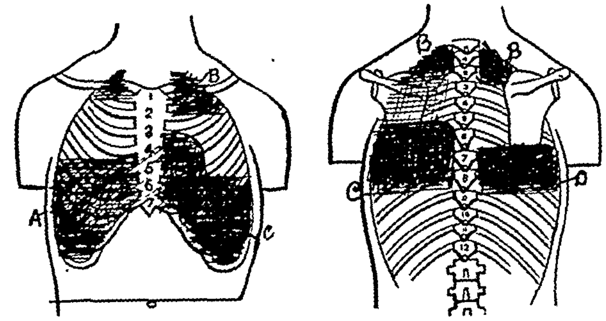

Fig. 2. Impaired resonance, vocal fremitus, and bronchovesicular expiration; C, distant breath sounds, fremitus and resonance feeble, pain, flat to percussion; D, friction sounds.

Course of the Disease.—The patient continued to lose weight and suffered from night sweats, accompanied by cough and large amounts of mucopurulent expectoration. He had several profuse pulmonary hemorrhages, and presented the clinical picture of chronic pulmonary tuberculosis.

Sputum: The sputum was examined for tubercle bacilli on sixteen different occasions, with negative results.

On January 14, Dr. Rosenberger reported the presence of streptothrix in the sputum.

March 7, the following report was received: "A great variety of bacteria. Organisms corresponding in morphology and tinctorial characters to the *B. fusiformis* of Vincent; cocci resembling pneumococci, a few streptococci, and various other unidentified species. No tubercle bacilli are demonstrable. A streptothrix is also present."

March 26, a special examination for Pfeiffer's bacillus proved negative.

March 29, the following physical signs were recorded: Clubbing of the fingers which has existed since admission has increased in degree.

Diagnosis.—Until the streptothrix was demonstrated in the sputum the diagnosis had been: "Chronic bilateral fibroid pleuritis, with infiltration and bronchiectasis (or cavity formation) of the left lung, probably tuberculous in origin."

Treatment.—This consisted mainly of stimulation with strychnin and forced feeding. Pain in the left chest was greatly relieved by strapping. Hemoptysis was treated by recumbency, ice bag to the chest, glonoin internally, etc. Santal oil was administered for a time in the hope of lessening expectoration and decreasing its fetid character, without any apparent result. Creosote in ascending doses was tried at another time and proved hardly more efficacious.

[7] Fraenkel: Pathologie und Therapie der Lungenkrankheiten, 1904.

Diet: During the greater part of the time the patient was given the regular "house diet." In February eggnogs were given between meals, and the patient was encouraged to take as much milk as possible. Soon after beginning improvement was noted, manifesting itself by gain of weight and strength. As soon as the patient was able to be out of bed he was made to spend the greater part of the day out of doors on the fire escape.

April 3, patient left hospital at his own request, against advice. His temperature, pulse and respiration were still irregular and abnormally high. The nephritis, according to chemical tests, had disappeared, but the patient had never voided more than 48 ounces of urine, the average being about 35 ounces. He had gained considerably in weight and said that he felt strong enough to "work on the farm."

Case 2.—P. T., Italian, aged 26, a laborer, was admitted to the Philadelphia General Hospital March 23, 1905, with the symptoms of left-sided pleuritis.

all history of preceding diseases, even in childhood; also of venereal disease and alcoholism.

Present Illness.—This began one month ago with cough, which increased as time went on and was accompanied with mucopurulent expectoration. During this time he lost weight rapidly, developed night sweats and anorexia, and had on two or three occasions attacks of hemoptysis.

Examination.—The patient is a well-developed man, fairly nourished. Pupils are normal. Moebius' sign was present in right eye. Chest is well formed. There is marked clubbing of the fingers.

Heart: There was marked accentuation of the aortic second sound; otherwise negative.

Spleen: This organ was palpable two inches below the costal margin.

Reflexes: The reflexes were apparently normal.

Lungs: There was diminished, delayed and restricted respiratory movement on the left side. Breathing was painful. The lower two-thirds of the left chest was flat on percussion, breath sounds feeble and distant, fremitus absent and resonance diminished. At the left apex, anteriorly, there was bronchovesicular expiration, fremitus and resonance were increased, and there was cog-wheel inspiration. Posteriorly, there were the same findings, with the exception of the last-named. At the right apex, anteriorly and posteriorly, there was vesiculobronchial expiration. Moist râles were heard from time to time diffusely throughout both lungs, mostly in the left.

Urine: Amber, acid, trace of glucose, no albumin, triple phosphates and amorphous urates.

March 26, 1905, pain in left side, incessant cough and copious, thin, mucopurulent expectoration remain the chief symptoms. There were irregular fever, night sweats (Figs. 1 and 2). The foregoing examination led us to believe that we had to deal with a case of pulmonary tuberculosis, with extensive involvement of the pleura. The sputum was examined for tubercle bacilli five times, with negative results. Finally a special examination by Dr. Rosenberger revealed the presence of streptothrix.

May 9, 1905, patient was more dyspneic and emaciated. Clubbing of fingers was more marked. Two urine examinations were entirely negative. Pain in the chest was relieved by strapping. Expectoration was thin, mucopurulent, sometimes almost aqueous in character and not infrequently amounted to over a quart in the course of twenty-four hours, thus pointing strongly toward the existence of a bronchiectasis. No definite physical signs pointing toward the existence or localization of such a lesion, however, could be made out, but the pleural thickening obscured the breath sounds almost entirely. Exploratory puncture of the left pleural sac yielded negative results. Despite the absence of chemical and microscopic findings in the urine indicative of nephritis, the patient persistently voided very small quantities of urine. This possibly was, in part, due to the large quantity of fluid eliminated in the sputum.

May 29, 1905, patient was in the same condition. He looked very ill, almost cachectic. He took nourishment badly and did not seem much benefited by extra diet of milk and eggs with which he was supplied. It was thought that he would, perhaps, do better if outdoor life could be instituted. To check the excessive expectoration, ascending doses of creosote were administered, without benefit, but the dosage amounted to only fifteen minims thrice daily. Further than this, treatment was stimulating—strychnin, glonoin, digitalis, caffein, etc. Temperature was still irregular.

Blood:

Erythrocytes, 3.560.000; leucocytes, 7,400. Differential count of leucocytes, as follows:

Lymphocytes	13.5 per cent.
Polymorphonuclear	77 per cent.
Hyaline forms	7 per cent.
Eosinophiles	2.5 per cent.

SUMMARY OF CASES.

The accompanying tabulation of twenty-six cases of pulmonary streptothricosis includes the hitherto reported cases, together with the two here recorded. The cases have been compared and contrasted from a clinical standpoint, the preceding articles having dealt almost exclusively with the pathologic and bacteriologic side of the question. From the study of these the following facts may be summarized:

Thirteen cases occurred in males, 5 in females, 8 no data. The youngest individual attacked was 12 years, the oldest 70. The course of the disease varied from one week to several years; the majority showed a duration of several months. Seventeen cases had the symptoms of pulmonary tuberculosis, most of these of the chronic variety. Twenty of the cases died—76 per cent.—2 improved, 2 remained stationary, 2 no data. Cultures and animal inoculations yielded positive results in 11 instances. Hemoptysis was recorded 6 times (23 per cent.) Pure streptothrix infection existed in 14, in 12 other organisms were coincidently encountered. Tuberculous lesions—old pulmonary scars—were found twice, tubercle bacilli once, scoliosis once. Various methods of treatment have been tried without definite or satisfactory results. The inhalation of medicated vapors had no effect. It would seem rational to presume that the best results would be attained by a therapy such as is employed in the various sanatoria for tuberculosis.

It will be noted that the two cases here reported present numerous features in common. Both suffered from inflammation of the pleuræ, accompanied by evidences of marked infiltration. Both expectorated very large amounts of mucopurulent matter and had irregular fever, hemoptysis and symptoms of vasomotor ataxia. Both continuously voided very small quantities of urine—often only from 14 to 16 ounces a day—without marked evidences of nephritis, despite the fact that they were imbibing large amounts of liquid diet. In their response to treatment, however, there was a marked difference in the two cases. The patient in Case 1, in whom the condition had apparently existed for a longer time, improved under treatment and left the hospital. The patient in Case 2, in whom the infection seemed more acute and virulent, became progressively worse. Despite the assertions of the patients to the contrary, we are inclined to believe that the disease had existed in both cases for a much longer period than the histories would lead us to believe; for it is hardly credible that such extensive and massive pleural thickening, even without the bronchiectasis, could take place in a short time. It is more than likely that, similarly to many cases of pulmonary tuberculosis, the incipient symptoms were of such slight and insidious nature that they were overlooked by the patient.

In closing we would like especially to emphasize our conviction that some of the many apparent cases of pulmonary tuberculosis, in which there is seemingly extensive tissue involvement, often associated with copious expectoration, in which repeated analyses of the sputum fail to reveal tubercle bacilli, if examined with the proper tinctorial agents, would reveal the presence of the streptothrix.

Improved Technic of Spinal Anesthesia.—Le Filliatre states that all the by-effects of spinal cocainization can be avoided by reducing the pressure of the cerebrospinal fluid as a preliminary. Whatever the pressure, he allows the fluid to flow until, instead of *spurting*, it drips slowly from the needle. He then reinjects always the same amount—10 c.c—mixed with the anesthetic to be employed. In an illustrated communication in the *Journal de Médecine de Paris*, he announces that he has never had a mishap in a total of 452 cases in which he has followed this technic. He thinks the varying experiences of others are due to the differences in the pressure of the cerebrospinal fluid at the moment of the injection.

Special Article

IMMUNITY.

CHAPTER XXV.

CHOLERA.

In 1883 Koch recognized microscopically in the stools of cholera patients, and by proper technic obtained in pure culture, the *Vibrio choleræ*, which stands to-day as the unquestioned cause of Asiatic cholera. The organism may be cultivated from the stools in every case of cholera, and is never found in the stools of normal individuals, except in the case of non-susceptible persons who are often encountered in the presence of an epidemic. Such persons are often a source of danger as unsuspected "cholera carriers." No other intestinal disease is accompanied by the presence of the vibrio of cholera.

Characteristics of the Organism.

Typically the cholera vibrio is about 1.5 microns long and one-fourth as broad. When freshly cultivated from the stools the cells of young cultures have the so-called comma shape which has given the organism the name of the comma bacillus. The form in reality is that of a segment of a spiral. When two cells are attached end to end an S-shape is commonly produced, and long spirals are made up of many cells which are joined at the ends. Old cultures show many deviations from the typical form, the cells assuming the form of thick rods or even appearing coccus-like. The vibrio possesses a single long flagella, which is situated at an end. Although two, four and six flagellæ have been described, Kolle states that such organisms are not cholera vibrios, but vibrios of another nature. In the character and rapidity of their movement, as seen in a hanging-drop, Koch compares the organisms to a swarm of mosquitoes. Old cultures may lose their motility to a large extent. The cholera vibrio does not form spores, although certain involution forms simulate them. It stains readily with the ordinary anilin dyes and is Gram negative.

Cultivation from the Stools.

The comma bacillus grows readily in various culture media of an alkaline reaction, certain appearances being characteristic; it is an obligate aërobe under artificial conditions, in spite of the fact that it flourishes in the intestines. The optimum temperature lies between 30 and 40 C. A very simple method of obtaining the organism in pure culture from the stools was discovered by Koch. In tubes of peptone bouillon which have been inoculated with the feces of a patient, the vibrio proliferates rapidly and within a few hours exists in almost pure culture at the surface of the liquid. Isolated colonies are obtained by transferring a small amount of the surface fluid to tubes of liquefied gelatin, then plating the latter. The colonies of cholera vibrio appear in a few hours as small translucent points from which pure cultures are made on a suitable medium.

Identification.

For more positive identification of the organism agglutination tests are performed with an artificially prepared anticholera serum. The Royal Institute for Infectious Diseases (Berlin) keeps on hand a dried serum of known strength (1-10,000) for this purpose. Tests are made in dilutions of 1/50, 1/100, 1/1000 and 1/2000, the final dilutions being so great that coagglutinins for other vibrios are practically eliminated. To the agglutination test may be added the "Pfeiffer experiment," in which the protective power of an anticholera serum is determined when guinea-pigs are infected intraperitoneally with the suspected culture. If the serum shows a protective power against this organism which approximates that shown against a known cholera vibrio, the diagnosis of cholera is justified. In performing such experiments the serum is mixed with the culture before injection.

Resistance.

The resistance of the cholera vibrio is very low. It dies in about two hours when dried (Koch) and on this account dust infection is thought not to occur. It is killed instantaneously by the boiling temperature, and in five minutes at 80 C. It is extremely susceptible to carbolic acid (killed by 1 per cent. in five minutes), corrosive sublimate (1 to 2,000,000 or 3,000,000 in from five to ten minutes), and to acids. Calcium chlorid is an efficient disinfectant when thoroughly mixed with the stools. The micro-organism lives in distilled water not longer than twenty-four hours, in ordinary water for several days to several weeks, and in one instance it was cultivated from the water of an aquarium after several months. Its life is short in the presence of putrefactive bacteria and rapidly-growing saprophytes, dying in sewer water in from twenty-four to thirty hours (Koch). Because of the large overgrowth of other organisms, the vibrio can rarely be cultivated from the stools of cholera patients for a longer period than from one to three days after death. Its life in and on foods depends on the reaction (alkalinity is favorable), and on the presence or absence of moisture. It lives longer in sterilized milk (ten days) than in that which contains other micro-organisms.

Infection Atrium and Dissemination.

The only infection atrium is the small intestine by way of the mouth and stomach. Infection by way of the lungs or through wounds does not take place. In the patient the living vibrio occurs only in the intestines, and it is excreted only with the feces. So far as known, it has no normal habitat outside the body, although a stream or other water supply may contain the vibrio over a long period through constant reinfection of the water. This can only occur, directly or indirectly, through the stools of patients. The washing of soiled linen or bathing in water which is used for drinking and other household purposes have caused outbreaks of cholera. The water supply of a city may be infected by the discharges of patients who are confined to a ship. Convalescents may retain virulent organisms in their stools for forty-eight days (Kolle), and, as stated, healthy persons who are insusceptible to cholera and who have resided in a cholera infected district, may carry virulent vibrios in their intestines. These conditions have contributed to the futility which to a large degree has met attempts to restrict cholera to limited districts by ordinary quarantine measures. In its extension from country to country cholera finds its way along the lines of travel. In some instances in which cholera has existed in pandemic proportions it has been possible to trace its source to the delta of the Ganges in India, a region in which the disease is endemic. Pilgrims from India have carried the infection to Mecca, and pilgrims from Egypt have carried it to their native land on their return from Mecca. Either from Egypt, or through Arabia, Asia Minor and Southern Russia or Turkey, cholera has with more or less rapidity extended to Western Europe. The development of rapid transit has increased the rapidity with which cholera may extend to distant parts. From Europe the disease has been carried to various ports of the western continent, Canada, the West Indies and southern ports of the United States, from which extension has occurred to different sections. Out of six widespread epidemics which occurred in the past hundred years, three have involved the United States, reaching considerable proportions. The means of introduction is not always apparent.

Epidemics.

As in typhoid, two types of epidemics are known, the two often being associated: First, that caused by water infection and, second, that in which the disease spreads by other means of indirect contact and by direct contact. The explosive character of an epidemic caused by infection of a water supply is much more striking than in the case of typhoid fever. In large cities hundreds, or even thousands, may be stricken within a single day. The brief incubation period, from twelve to twenty-four hours, contributes to the acuteness of the outbreak. The distribution of a "water-borne" epidemic corresponds with the distribution of the infected water. A remarkable occurrence illustrating this point was noted in the epidemic which attacked Hamburg in 1892. In certain streets in which the residents of the two sides obtained their water supply from different sources, one of which was infected, cholera was limited to that side which was supplied with infected water. Only irregular cases due to contact infection occurred on the opposite side of the street.

Epidemics which are due solely to contact infection develop slowly and irregularly. A common incident is the successive involvement of the members of a family, whereas others in the immediate neighborhood are unaffected. Water borne epidemics are invariably complicated by the occurrence of contact infection. The methods of contact infection are not different from those mentioned under typhoid fever. Food or milk which has been infected by contaminated water or by other means may cause the development of isolated groups or cases.

Susceptibility of Animals.

So far as known, no animal undergoes spontaneous infection with cholera. By rendering the gastric contents of guinea-pigs alkaline and introducing cultures into the stomach through a tube, Koch induced a cholera-like process from which the animals died within from twenty-four to thirty-six hours; an intraperitoneal injection of opium, to quiet peristalsis, seemed to be necessary for the success of the experiment. Similar results were obtained in very young rabbits by feeding cultures to them (Issaeff and Kolle, Metchnikoff). Guinea-pigs withstand the subcutaneous inoculation of moderate amounts, but are very susceptible to intraperitoneal inoculation. Intravenous injections are exceedingly toxic for rabbits, and a fatal cholera-like condition with localization of the organisms in the intestines and intestinal mucosa has been produced in this way (Thomas).

Susceptibility of Man.

A number of cases are recorded in which investigators while working with cultures have become infected with cholera, the cases running typical courses which sometimes ended fatally (Pfeiffer, Pfuhl and others). That not all persons are equally susceptible to the disease is shown in the few instances in which infection has been attempted deliberately; some contracted the disease, at least one case ending fatally, whereas in others either a mild infection or none at all took place.

Endotoxin.

The essential poison of the cholera vibrio is intracellular, and becomes free only after solution of the bacterial cells. Cultures which are killed carefully as by chloroform vapor (Pfeiffer) are highly toxic, although the fluid alone is non-toxic. Young cultures entirely free from bacteria have little or no poisonous action. The toxicity of older bouillon filtrates is due partly to solution of the bacteria with consequent liberation of endotoxin, and perhaps also to secondary disintegration products which have a certain toxicity. The soluble toxin of Metchnikoff, Roux, and Taurelli-Salimbeni is a dissolved endotoxin and not a secretion of the living cells, according to Kolle.

Pathogenesis.

Koch considers that cholera is an acute infectious process involving the intestinal epithelium, whereas the general condition is one of acute intoxication. It is assumed that the condition in the intestines corresponds to that in the culture media, i. e., that here,too, no true soluble toxin, comparable with that of diphtheria or tetanus, is secreted, but that the toxin which eventually reaches the circulation is that which is liberated from the bacteria after the latter have been dissolved by the bacteriolysin of the plasma, or perhaps by the leucocytes. Doubtless a great deal of endotoxin is liberated in the intestinal canal, but it is Koch's conception (cited by Kolle) that the primary intoxication comes from those organisms which have penetrated between and beneath the epithelial cells and here have undergone solution. One effect of the toxin in this situation is to cause desquamation of the intestinal epithelium, as a consequence of which rapid absorption of the toxin from the intestinal canal takes place through the denuded surface. This theory supposes that the toxin is not readily absorbed through the intact epithelium. The living vibrio has never been cultivated from the blood.

The changes in the intestines depend on the duration of the infection. In cases which prove fatal within a few hours the mucosa shows only moderate general reddening, which is intensified at the borders of Peyer's patches and the solitary follicles. The intestinal contents are of a rather clear fluid nature in which are suspended flakes of mucus and epithelium; the fluid may be tinged with blood. With a longer duration of the disease the destructive processes in the mucosa become more intense, and consist largely of desquamation of the superficial epithelium and intense congestion of the denuded submucosa. In the more prolonged cases, "cholera-typhoid," the mucosa, especially above the ileocecal valve, may show diphtheritic necrosis. The serous surface of the intestines is injected. The kidney shows parenchymatous degeneration.

(To be continued.)

Clinical Report

A CASE OF GENERAL INFECTION BY THE DIPLOCOCCUS PNEUMONIÆ.

BLANCH N. EPLER, M.D.
KALAMAZOO, MICH.

Patient.—Mrs. P., aged 26. Family history negative. The patient had lived a questionable life, and about three years ago, after failing in general health, she was thought to be dying. No specific history could be obtained.

Examination.—The physician called found the patient with a high fever, coughing and expectorating. Right lung was tympanitic in areas and dull in other areas. The sputum was examined several times for the tubercle bacillus, but none was found. There were macular-like blotches on hands and face, especially on the forehead; there were lesions of herpes on the lips, which were swollen; there was no itching, no pain.

Treatment.—No diagnosis was made, though the patient was put on tuberculosis treatment. She seemingly recovered and the macular eruptions scaled off.

Subsequent History.—On June 22, 1905, my attention was called to the patient, who had been treated by the city physician, Dr. John B. Jackson. Seven days previously the patient complained of fever, vomiting and slight discomfort in the left elbow. During the five days after onset, temperature, pulse and respiration increased, but with no signs in the lungs or elsewhere to account for the symptoms. At the end of five days, the right lung showed distinct signs of pneumonia in the upper lobe and the elbow became swollen, red and tender. The urine showed much albumin, with coarsely granular and hyaline casts.

June 22: The seventh day after coming under medical care the pulse was 150, temperature 102, respiration 78, and the abdomen was distended. Till she died she was conscious, not especially weak, but very cyanotic and distressed.

Autopsy.—The autopsy showed some interesting points, and these only will be mentioned.

Pleuræ: Under the sternum, there were pleural thickening and adhesions, which, on examination, showed no tubercles; there were many pus cells, many blood vessels containing pus cells, hyaline degeneration and small, round-cell infiltration.

Lung: In the right upper lobe, there was gray hepatization; the remainder of the lung was edematous and congested. There were hemorrhagic areas and many pus cells.

Glands: The bronchial lymph glands showed congestion.

Kidney: The kidneys were congested, and in the cortex there was some small round-cell infiltration and an increase in the connective tissue.

Pelvic organs: These were normal, except for one or two small ovarian cysts.

Heart: This organ was slightly enlarged; the right ventricle was empty except for a large white clot, which obstructed the valves and extended into the auricle and pulmonary artery, the wall of which was of unusual firmness, white and glazed.

Right elbow: This was swollen, firm and red. On opening the joint a thin yellow pus presented, smears and cultures from which gave pure *Diplococcus pneumoniæ*. There was no erosion. Cultures and smears from the heart's blood and lungs gave pure cultures of the *Diplococcus pneumoniæ*.

Pathologic diagnosis: Purulent pleurisy: gray hepatization of right lung: antemortem clot; general infection and localized infection, with *Diplococcus pneumoniæ*.

Compulsory Notification of Tuberculosis.—This is a notifiable disease in Victoria. The *Intercolonial Med. Jour.* states that a physician has been fined for not complying with the law.

THE AGGRESSIN THEORY.

Virulence, resistance, susceptibility and the like are terms commonly used with reference to infectious diseases to express certain properties of the infecting and the infected organisms. While they are useful, still it is true that very little is known of the real nature of the conditions designated. A great part of the experimental work now being done in infectious diseases is carried on with a view of making our knowledge on such points more precise and it is probable that in time these words will be replaced by more exact ones as new facts accumulate. Metchnikoff's phagocytic theory, Ehrlich's side-chain theory, the opsonic theory of Wright and Douglas have been of great service in elucidating many of these little understood phenomena and are opening up new problems of great practical importance.

A further contribution has recently been made to the problems of virulence and immunity in the form of the "aggressin theory" of Bail.[1] Apparently it grew out of an attempt to explain the so-called "phenomenon of Koch"—an observation made years ago by Koch—to the effect that tuberculous animals when inoculated intraperitoneally with a fresh culture of tubercle bacilli succumb quickly to an acute attack of the disease, the resulting exudate containing almost exclusively lymphocytes. Bail found that if tubercle bacilli, together with sterilized tuberculous exudate were injected into healthy guinea-pigs, the animal died very suddenly, i. e., in 24 hours or thereabouts. The exudate alone had no appreciable effect on the animal, while inoculation with tubercle bacilli alone produced death in a number of weeks. He, therefore, concludes that there is something in the exudate that allows the bacilli to become more aggressive, and hence has called this hypothetical substance "aggressin." He thinks it is an endotoxin liberated from the bacteria as a result of bacteriolysis and that it acts by paralyzing the polynuclear leucocyte, thereby preventing phagocytosis. Heating the exudate to 60 C. increases its aggressive properties rather than diminishes them and small doses act relatively more strongly than larger ones. These facts he explains by assuming the presence of two properties, one that prevents rapid death, is thermolabile and acts feebly in small doses, and one that favors rapid death and is thermostabile. He assumes that in a tuberculous animal the tissues are saturated with the aggressin and when fluid collects in the body cavities, as it does on injection of tubercle bacilli, it contains large quantities of aggressin which prevent migration of the polynuclear leucocytes, but not the lymphocytes, and hence allows the bacilli to develop freely, producing acute symptoms. In the peritoneal cavity of the normal animal, injected with tubercle bacilli, on the other hand, are large numbers of polynuclear leucocytes which engulf the bacilli, thus inhibiting their rapid development, there being here no aggressin to prevent phagocytosis.

Now this theory has been applied to a number of infections, including typhoid, cholera, dysentery, chicken cholera, pneumonia and staphylococcus infections. In all similar results have been obtained as with tubercle bacilli. When exudates, produced by virulent cultures of these various organisms and properly sterilized, are injected with fresh cultures into an animal, death occurs in much shorter time than when the organisms alone are injected.

Moreover, it has been possible to immunize animals against these various infections by repeated injections of the aggressin in the form of exudates. This results in the formation of an "antiaggressin," which opposes the action of the aggressin, thereby enabling the leucocytes to take up the bacteria and thus to protect the animal. This has been done in staphylococcus, dysentery, typhoid, cholera, pneumococcus, and chicken cholera infections in animals. In addition a very marked agglutinative property of the blood is acquired for the bacteria in the animals so immunized.

Naturally, a theory of this kind is certain to be criticized and we find that Pirquet and Schick[2] have raised the objection that is entirely unnecessary to assume the presence of an "aggressin," concluding that all the facts observed can be explained by the formation of antibodies by the tissues. They also call attention to the fact that analogous phenomena of hypersensitiveness occur in other conditions than bacterial infections, as, for instance, in the so-called "serum disease" (*Serumkrankheit*) in which after one injection of alien serum a second injection of serum may cause very profound and acute symptoms.

It is a curious fact that in the several contributions already made on this subject by the German investigators apparently not one word has been said with reference to the possible rôle that the opsonins of Wright and Douglas may play in the explanation of the phenomena described. The opsonic theory, i. e., that certain substances in the serum prepare bacteria for phagocytosis, certainly rests on a secure basis. In the normal animal phagocytosis may be assumed to take place freely because opsonins are present in the fluids; in an infected organism the opsonins may be reduced in amount; we know that many bacteria, living and dead, absorb opsonin. Consequently, the exudates and the tissues of the infected animal would contain less opsonin. Hence phagocytosis would be diminished, and bacteria injected under these circumstances would develop more freely and largely unimpeded by the natural defenses so far as represented by phagocytosis. When sterilized bacterial exudates are injected, the opsonins normally present may be fixed by bacterial remnants and possibly neutralized also by proteins and other substances in the exudate. We know that complements and opsonins are very sensitive to chemical and other influences, and the introduction of exudate with bacteria, as in Bail's experiments, may, therefore, neutralize so much opsonin that active phagocytosis is suspended. Opsonins are destroyed by heating serum from 60 to 65 C. and this may explain the greater activity of infection described by Bail on injecting heated exudate; in this case, the little opsonin possibly present in the exudate was destroyed and phagocytosis still further crippled. Bail's explanations of the effect of heat on the exudates certainly appear somewhat labored. Now, what has been said here with reference to opsonin and its fate in infected animals and by mixture with exudate applies with equal force to complements on which depends the destruction of bacteria by lysis. For these and other reasons that can not be discussed now, it is evident that Bail's "aggressin theory" requires much further investigation, with special reference to opsonins and complements before its real value may be determined.

CELL PROLIFERATIONS IN GROWTH CENTERS AND THEIR RELATIONS TO REGENERATION AND TO TUMOR FORMATION.

Through the researches of embryologists it has been learned that, during the development of the more highly differentiated multicellular organisms, the cell divisions by karyokinesis, which are at first diffusely and more or less evenly distributed over the whole "cell state," gradually come to be definitely localized and regularly grouped. This localization and grouping of the karyokineses is a process which stands in intimate causal relation to the shaping of the form of the embryo, inside and out, as well as to the differentiation of the individual organs. In the places, then, where karyokinetic figures are met with in numbers, we have to deal with "construction centers" of the living substance, with areas of most intense growth; a study of the disposition of areas rich in karyokineses is, therefore, of the greatest importance for the localization of growth processes in a developing organism.

In the earliest embryonic period of higher organisms, all the tissues and organs grow by an increase of all their cellular components as long as the cells retain a more or less embryonic or indifferent character. As soon, however, in the course of the histologic differentiation of an organism and its parts, as the individual cell components have assumed a special structure and function and have become, to a certain degree, different from the type of the embryonic mother cell, the conditions of growth change. The specialization of function of the different cells occurs *pari passu* with a depreciation in omnipotence. The more highly differentiated a cell becomes, the more limited it is in the morphogenetic and physiologic potencies of the embryonic cell, until finally it loses temporarily, or even permanently, the capacity for proliferation. Thus, the majority of cartilage cells, bone cells, nerve cells, sensory cells, etc., are largely excluded from proliferative processes relatively early in development. Certain cell groups in these tissues, however, remain embryonic in character, more or less undifferentiated; these are the so-called growth centers, and in them alone is the capacity for cell proliferation retained. Schaper and Cohen[1] have recently made an exhaustive analysis of these growth centers in epithelial tissues and organs and in the central nervous system and sense organs. Their studies, they believe, have an important bearing on regeneration and tumor formation.

Schaper and Cohen assert that it is the persistence of a latent capacity for proliferation in these special growth centers that accounts for the phenomena of regeneration after pathologic disturbance of local correlations of cell function. If the pathologic condition destroys these growth centers, regeneration is impossible. For some tissues in man (ganglion cells, for example), no growth centers persist in the adult at all, and they never regenerate when once destroyed. A few tissues possess the power, even after differentiation, to regenerate by proliferation under special environmental conditions. The lower the degree of differentiation, the greater the power of regeneration; the connective tissue cells, for example, which are but little differentiated, possess great proliferative capacity, as do the epithelial cells which are arranged in one layer. In most tissues, however, only special areas or centers of undifferentiated cells persist, and it is these which participate especially in the processes of repair. When bone is injured, repair, if it is to take place, must be brought about by proliferation of the layer of osteoblasts on the inner surface of the periosteum. If the epidermis is to be regenerated, the palisade cells of the Malpighian layer are the ones to multiply. In necrotic processes in the intestine with formation of ulcers, as in typhoid fever, healing occurs through multiplication of groups of cells at special sites in the crypts of Lieberkühn, where the cells permanently retain an undifferentiated, embryonal character. In the uterus, after menstruation or during the puerperium, the mucous membrane is regenerated from the special "growth centers" in the fundi of the uterine glands. In glands like the liver, kidney and pancreas, some portions of the gland tubules remain less differentiated than others, and it is the cells of these which multiply in regenerative processes. Thus, in cirrhosis of the liver, the regenerative capacity of the finest interstitial bile ducts becomes evident; in diseases leading to regenerative processes in the kidney, the cells of the straight tubules (not the convoluted) are able to multiply.

---

[1] Schaper, A. u. C. Cohen, "Ueber zellproliferatorische Wachstumzentren und deren Beziehungen zur Regeneration und Geschwulstbildung," Arch. f. Entwckgsmech d. Org., Leipz., xix, 1905.

In view of the demonstration of the relation of these "growth centers" to normal development and to physiologic and pathologic regeneration, it is not surprising, perhaps, that Schaper and Cohen should attempt to press them into service to help to explain the origin of atypical non-inflammatory new growths or tumors. It is remarkable how frequently the "growth centers," or the places where embryonal karyokinesis persists longest, turn out to be sites of predilection for the development of tumors. It seems likely that the more exact localization of the "growth centers" will permit us better than ever to localize the starting point of tumors. Thus, if the theory be correct that tumors begin in the "growth centers," then it is likely that primary tumors of the liver will be found to begin in the finest biliary passages, tumors of the intestine in the depths of Lieberkühn's crypts, tumors of glands in the portions of their tubules which are least specifically differentiated, tumors of the epidermis in the Malpighian layer, chondromata in the perichondrium, gliomata in the ependymal wedges in the central nervous system. Thus far but little is known regarding the exact beginnings of tumors, but certain observations tend to support Schaper and Cohen's hypothesis. Partsch, for example, has found that the so-called "root cysts" of the teeth arise from elements of the epithelial sheath of the enamel organ; Ribbert believes that primary tumors of the liver do actually begin in the interstitial biliary capillaries; epithelial cerebral tumors appear to rise most often from the cells of the lowly differentiated choroid plexus.

The view that tumors have their origin in the "growth centers" accords very well with the Cohnheim-Ribbert hypothesis regarding the origin of neoplasms. The latter assumes (1) the presence in the body of cell material capable of proliferation, and (2) a stimulus which incites the abnormal proliferative activity, probably the result of the separation of the particular "embryonic" cell material from its normal organic connections and inhibitions. Schaper and Cohen localize the "proliferative cell material" in their "growth centers."

CONGENITAL TUBERCULOSIS.

There is evidently to be another swing of the pendulum of medical opinion with regard to the inheritance of tuberculosis, and, indeed, it is already well on the path of its next excursion. While a quarter of a century ago tuberculosis was universally conceded to be mainly a matter of heredity, in recent years medical opinion has gone almost entirely to the other extreme and has considered that the direct inheritance of tuberculosis is rather rare. Very few physicians were ready to concede that there was not at least an inherited predisposition to tuberculosis, but the actual transmission of the bacillus *in utero* was considered to take place only very rarely. The idea of contagion, then, practically entirely replaced that of heredity, and if children suffered more frequently from tuberculosis than older persons it was mainly because they were more exposed, and then, too, because they had less vitality resistant to the disease.

One excellent feature of this set of medical opinions with regard to the contagion rather than to the heredity of tuberculosis we hope will be maintained in spite of the change in medical opinion that we foresee. With the idea of contagion in mind, it is recognized that children playing about the floor are much more likely to come in contact with the bacilli of tuberculosis if there are any inmates in the household suffering from the disease and who are at all careless of the precautions necessary to protect others. This means not only carelessness in the matter of direct expectoration, but lack of care when coughing to keep something before the mouth in order to prevent the widespread distribution of material from the lungs on the atomized particles of sputa, which may be coughed to a considerable distance under such circumstances. As the result of the recognition of these dangers much good undoubtedly was accomplished.

There seems no doubt now, however, that the direct transmission of tuberculosis from mother to child is much more frequent than has been imagined. At the meeting of the National Association for the Study and Prevention of Tuberculosis, Dr. Wm. H. Welch of Baltimore declared that there are now many cases in which the presence of congenital tuberculosis has been noted. The principal proof for this is the great frequency with which tuberculosis of the placenta occurs in tuberculous women. Very few mothers who are suffering from tuberculosis in an active form fail to present tuberculous lesions of the placenta, when a careful investigation of that organ for this purpose is made. These lesions occur not only in advanced cases of tuberculosis, but also in the placentæ from patients who present scarcely more than the manifestations of incipient pulmonary tuberculosis. The disease must be in an active and not in a quiescent form, but it has been noted more than once that the strain of pregnancy itself seems to be sufficient to make a hitherto latent tuberculosis awaken into an activity that may prove dangerous for the offspring.

Dr. Welch considers that the rise in infant mortality from tuberculosis, which occurs during the second quarter of the first year of infant life, indicates that there has been a probable infection of the child during the latter part of the intrauterine existence. The incubation period of tuberculosis is not definitely known, but it is considered to be at least of several months' duration. If infection should take place, then, during the last three months of pregnancy it would be within the bounds of probability that the active manifestations of the disease would appear only some three to six months later.

It is not at all surprising that lesions of the placenta should be found. It is now well known that whenever tuberculosis is active and progressive, even though it may be only in an incipient stage, tubercle bacilli find their way into the circulation. They have been discovered repeatedly in the urine, having passed through a healthy kidney without causing serious effects. Not infrequently, however, their passage through the kidney gives rise to an irritative congestion causing a sense of weight in the loins of which consumptives not infrequently complain. That bacilli thus present in the circulation occasionally should find a resting place in the large vascular spaces of the placenta, where the circulation is less active, is only to be expected.

THE RED LIGHT TREATMENT OF SCARLET FEVER.

The treatment of the eruptive fevers by red light is no new proceeding, as there is some evidence that the Chinese and also some European nations employed it centuries ago. That they applied the treatment in the form now suggested seems doubtful, and there is evidence that they neglected to exclude ordinary light from the sick room, and that the hanging of the room with red draperies, and sometimes wrapping the limbs in red cloths, constituted the red light treatment of early days. Toward the end of the last century the work of Finsen put the matter on a scientific basis, and renewed the interest in this form of treatment. The philosophy of the treatment is based on the well-known fact that the so-called chemical rays in light, the blue, violet and ultraviolet, are capable of setting up inflammation in the healthy skin, and therefore are certain to aggravate the inflammation in a skin already diseased from some other cause. Finsen suggested the use of the red light treatment in smallpox particularly, and the results reported have varied, though they have been most encouraging. when the reporter closely followed Finsen's directions. This method of treatment has also been followed with some success in erysipelas, especially by Krukenberg, who has reported both improvement in the skin condition and rapid decrease in the temperature.

Quite recently Cnopf[1] of Nürnberg has reported some results with the red light treatment of scarlet fever which are distinctly encouraging. The method of applying the treatment in these cases is important, as all daylight must be permanently excluded until the eruption of the disease has completely disappeared. The windows for their lower two-thirds should be covered with some tissue completely impermeable to light, while the upper one-third should be covered with ruby red silk. At night the room should be treated as a photographic dark room and only lights with red shades should be allowed. The importance of completely excluding everything but the red rays is demonstrated by some of Cnopf's experiences. He found that even after the scarlatinal rash had apparently disappeared exposure to daylight for two or three minutes sufficed to bring it back. He was compelled, therefore, to make this test in all cases before allowing patients to be subjected to ordinary light. The effect of the red light treatment on scarlet fever is twofold. The fever, which under ordinary treatment usually persists until the rash fades, falls, almost by crisis, and reaches normal in three or four days instead of in seven or eight days, as is the case under ordinary treatment. The skin lesion is also markedly affected, the red color so characteristic of the disease gradually fading. The complications of the disease are apparently not affected, as in several of Cnopf's cases secondary angina or pneumonia served to cause an increase in the fever as usual.

The question naturally arises whether it is the red light or merely the exclusion of all light which is responsible for the changes noted by Cnopf. The query is an old one. Years ago it was noted that exclusion of all light from smallpox patients led to less pitting than daylight treatment. Cnopf, however, thinks that the mere exclusion of daylight is not the responsib'e agent. but that the red rays have an actual curative effect. How this effect is produced he does not pretend to say. However much we may be lacking in explanations of these observations, and however much we may doubt the actual value of the treatment, the success achieved seems to indicate that the method is worthy of more extended trial.

COLLIER'S WEEKLY AND PATENT MEDICINES.

One of the most encouraging signs of the times is the fact that several lay journals have come out against the patent medicine evil. The opposition in most instances, however, consists in simply refusing to accept patent medicine advertisements of any kind. The most persistent, consistent and logical fight is being waged by *Collier's Weekly,* and there is scarcely a week but something appears that is to the point. Here is its comment on peruna and yellow fever, to which we referred editorially last week. It bears the heading, "Murdered by Advertisement."

> Patent medicine horrors never reached a point of deeper degradation than in the yellow fever troubles of the South. Mr. Samuel H. Adams, whose series of articles will begin probably in five or six weeks, will hardly have anything more startling to narrate than the incredible performance of "Peruna" in alliance with the New Orleans *Times-Democrat.* This sheet has accomplished a feat of prostitution which, considering its pretense to respectability, probably sets the record. While the South is struggling to check a peril of the direst magnitude, this newspaper publishes an interview with "Dr. Hartman," with the familiar allegation that he "said in part," and all other devices to make it look like an important piece of news. Its headlines are: "How to Avoid Yellow Peril. An Interview with Dr. Hartman Concerning the Yellow Plague." To the reader this is the genuine opinion of a physician. He can not know that Dr. Hartman is the head of the Peruna Company, and that the *Times-Democrat,* in whom the reader presumably has some trust, is selling itself and the safety of its constituents for a bag of gold. "A summary of this interview," the *Times-Democrat* informs us, "is being spread broadcast over the United States *for the benefit of yellow fever sufferers.*" The gist of it is that, while screens

---

[1] Münch. med. Wochft, No. 32, 1905.

> and other precautions are advisable, Peruna should be taken at once and continued during the whole course of the epidemic. "'I feel sure,' the doctor went on to say (!), 'that any person following this advice is in no danger of taking yellow fever.'" For anybody who believes we have taken too seriously the patent medicine evil and newspaper complicity therein, this unspeakable outrage should be a lesson. Is there anything to which men can not be led by money? To own a newspaper and hire it out to perilous fraud in an emergency like the yellow fever danger almost surpasses one's belief in human greed. No more disheartening proof of the need of the crusade which we have begun could possibly have been offered.

Evidently the writer of this article thought that the *Times-Democrat* was the only newspaper at fault. This is not true. Many of the Southern newspapers had the same advertisement inserted as telegraphic news, and these should accept with as good grace as possible the righteous castigation given them by *Collier's Weekly*. We understand that Mr. Samuel Hopkins Adams, who for months has been quietly conducting an investigation for this purpose, is preparing a series of articles for the weekly which will state facts regarding patent medicines in plain language. Judging from the following, he will also take up the quack doctor side:

> The quacks are not to be omitted. The same investigator, whose inquiries into patent medicines are almost completed, is gathering material about medical abuses also. He hopes to have the opening article ready for publication in September. It will give an outline of the patent medicine industry, and will be followed by a number of articles on particular medicines and groups of medicines, beginning with Peruna. The quacks will follow in their turn.

Collier's Weekly deserves the support of every member of the medical profession.

THE EPIDEMIC RECEDING.

The situation in New Orleans continues to improve, while in the remainder of Louisiana there are some seriously infected points, but there is no longer a general increase of new cases and foci. The storm center of news for the past week has rested in Mississippi, with a lively subsidiary center at Memphis. Another town conspicuous for its boasted "air-tight" shotgun quarantine—Vicksburg—has been compelled to admit the presence of infection. In the case of several towns, infection has been discovered, or admitted, only after a person recently from the town has fallen ill with the disease elsewhere, thus leading to a tracing back of the infection. A notable and welcome feature of the week's news has been the *volte* face of Governor Vardaman. His views on quarantine and on methods of fighting the epidemic have come quite into accord with those of the best posted medical men, and for this much credit is due his willingness to be convinced. Arkansas has witnessed the most depressing of the week's events. Governor Jefferson Davis set aside the quarantine methods of the State Board of Health and four medical members, including the president and secretary, promptly resigned. Governor Davis also refused Surgeon-General Wyman's request to permit Passed-Assistant Surgeon Goldberger to pass by rail through a few miles of Arkansas in order to reach another point in Louisiana where his services were badly needed. From Southern Illinois comes news that persons turned back by the quarantine at Cairo are going up the Ohio and Wabash rivers and then entering the state. Along the Gulf coast the infection steadily spreads in mild form. So far as New Orleans is concerned, it now seems possible to state that modern methods have won. It is depressing to read that it was necessary to arrest a physician for failing to report cases. As a whole, the medical profession and the majority of the citizens are pulling together splendidly, and the result already is a matter for pride.

HEPATIC TOXEMIA AS A LATE EFFECT OF CHLOROFORM.

Of late years chloroform has been generally recognized as a more dangerous anesthetic than some others. Its toxic action, however, is usually manifested early, and as regards late effects it has been considered, perhaps, even safer than ether, the irritant action of which on the lungs, etc., is often dreaded. The communication of Drs. Bevan and Favill in this issue of The Journal and the extensive literature of similar cases which they quote suggest a peril in the late effects of chloroform which is evidently not generally recognized by the profession. It is probable, as they point out, that in many cases hepatic toxemia from chloroform is slight and shown only by transient jaundice and nervous symptoms of comparatively slight import, but that it may be overwhelmingly fatal seems to be indicated by the case they report and by others that they quote. The dangers of prolonged administration of chloroform are shown by the fatty-liver degeneration produced in animals, which should itself be a warning against its prolonged use in any surgical operation. Its danger in young children and under the special conditions which Bevan and Favill enumerate as increasing the susceptibility to these late effects should be considered. It is not likely that chloroform will pass altogether into disuse, at least not until some efficient substitute, with all its advantages, has been discovered, but we are learning apparently more of its dangers all the time. It is something of a question whether, while underestimating the possible late effects of chloroform, we have not also overestimated those of ether. There seems to be much yet to be learned about anesthetics and their use.

THE SANITARY PROBLEM OF PANAMA.

Professor Vaughan's communication elsewhere in this issue states the conditions of success in the construction of the Panama canal as succinctly and forcibly as can be done. That the problem is first of all a sanitary one is well known to all medical men who have paid any attention whatever to the conditions existing on the Isthmus. Nevertheless, the difficulties which it involves have been too much ignored and, as Dr. Vaughan says, this was the main reason of the failure of the French canal company to complete its work. The canal can be built, as he admits, without special measures for sanitation, but at a cost of human life and treasure that is almost incalculable, to say nothing of the danger he mentions of involving other regions. The first thing to do is to render the region habitable for the great number of laborers of whatever nationality that will have to be employed for years in the excavation and construction work. The task will be easier for us than for our predecessors, since we know more of the natural history of the diseases that must be combated. It is not the yellow fever that really is the most formidable of these. The ever-present malaria, especially in its pernicious form that is so common on the Isthmus, is a far more dangerous because a more persistent and less manageable foe. That the mosquito can be absolutely eliminated as a disease factor, especially on the low Atlantic side, is perhaps too much to expect, but malaria can be controlled even there to a great extent. It is a comparatively small part of the work at most that remains to be done in that region, and over the rest of the line of the canal the natural conditions are far more favorable. It is possible, moreover, that besides the protective vaccination from yellow fever suggested by Professor Vaughan, a careful study of the subject may develop some method of procuring sufficient immunity against the more serious forms of malarial disease or some parasite, as he intimates, that may be fatal to the mosquito. If the canal work can develop such results, it will be worth more to the world than the commercial value of the completed link of transit from ocean to ocean. Such an idea is not altogether visionary. No one expected from our contest with Spain sanitary results such as were attained, and which have been justly said to have been worth more than all the conflict cost. Aside from such possibilities, however, the sanitation of the Isthmus, to a very large extent, is practicable with the means at hand and it is a misfortune that these have not been fully utilized before. There are encouraging indications that the present executive management of this great work appreciates these needs and is taking steps to meet the conditions much in the way that our correspondent indicates. The undertaking is a national one. Our reputation as a people is largely involved in its success. It will be a pity if, through failure, it discredits American intelligence and efficiency. It is only by availing ourselves of every possible aid that sanitary science can give that the work can be creditably and successfully accomplished.

CASUALTY FRAUDS.

Continued exposure of the methods of those who make a business of getting injured and of collecting damages gives strong promise of ruining the industry. Theodore Waters contributes a fourth paper (in September *Pearson's*) recounting his own experiences in alleging accidents that never happened. In one city he was "hurt" early in the morning, and before noon lawyers' runners urged him to sue on a contingent fee contract, offering to furnish without additional charge all necessary witnesses and testimony. Once the retainer contract is signed the really injured person is thereby prohibited from accepting any proffered settlement, except through the retained lawyer. This shyster lawyer fees court attachés, hospital internes, police, notaries and factory foremen, all of whom can furnish valuable information and assistance. It is alleged that Chicago presents the largest number of illustrations of the "fake doctor" working with the "shyster lawyer" to defraud corporations. "For it can be laid down as an axiom that if there were no shyster lawyers, or doctors whose practices are without the code of medical ethics, there would be no profession of getting hurt." The strenuous methods of the medical profession to rid itself of this and similar impediments are not mentioned, probably because unknown to the writer. On the other hand he speaks decidedly of the evident degeneration of the morale of the legal profession during the last fifty years.

THE SIGNIFICANCE OF ACETONURIA FROM THE SURGICAL STANDPOINT.

The appearance of acetone in the urine has long been recognized as a danger signal in cases of diabetes, although investigation leads to the belief that the symptoms of intoxication often present under such conditions are in reality due to diacetic acid and B-oxy-butyric acid, of which the acetone appears to be a forerunner. The important practical significance of the detection of this state of acidosis resides in the possibility of neutralizing the condition by the administration of sodium bicarbonate. It has been observed further that a similar condition is not rarely encountered in cases that pursue an unfavorable course when submitted to anesthesia for the purpose of surgical intervention. With the object of determining the validity of previous observations and inferences in this connection, Dr. Joshua C. Hubbard[1] examined for the presence of acetone and diacetic acid the urine from 145 patients admitted during the summer of 1904 to one of the three surgical services of the Boston City Hospital. Acetonuria was found in 9 cases, associated with diacetic acid in 4, but all of these pursued a course perfectly consistent with the injury or disease present, and in none could any abnormality in convalescence be discovered that could be attributed to the state of the urine. In 4 of these cases diacetic acid also was present in the urine. In 5 cases in which acetone or diacetic acid or both were found during convalescence there was possibly a momentary disturbance, which yielded readily to treatment with sodium bicarbonate, administered in doses of 30 grains thrice daily or oftener. In 2 cases in which alarming symptoms developed and acetone was found in the urine, death ensued. The conclusion is accordingly reached that the presence of acetone in the urine, alone or in association with diacetic acid, in conjunction with symptoms of themselves alarming, especially vomiting, adds to the gravity of the prognosis.

COMMENDABLE SOCIETY WORK.

As the organization movement gathers momentum, medical societies here and there meet emergencies with effective society action. These deserve mention both to receive merited praise and, more particularly, to let all other societies know of the work accomplished and of the methods employed. By knowing what others are doing, local societies will be stimulated to do better work for the public and for the profession. A notable recent instance of collective medical aid to a suffering community is a "Circular of Information addressed to the Medical Profession for distribution among Trained Nurses and others entrusted with the care of yellow fever patients," that has been issued in attractive, well-printed form by the Orleans Parish Medical Society—at New Orleans. The circular is composed especially of an extract from the proceedings of the society's meeting on August 12, 1905. At this meeting Dr. Rudolph Matas addressed the society on "New Duties and Responsibilities Imposed on Trained Nurses and Other Persons Entrusted with the Care of Yellow Fever Patients, in Consequence of the Newly-acquired Knowledge of the Mode of Transmission of this Disease by the Mosquito." He pointed out the fact that the physician could only give the directions as to the new methods of prophylaxis, while others must execute them. In all, the brochure contains but 13 pages of well-digested and well-classified information regarding mosquitoes, fumigation, prophylaxis, etc., and it is admirably adapted to its purpose as well as being a very creditable medical society enterprise.

---

Medical News

ILLINOIS.

Smallpox.—Four cases of smallpox are said to have developed in Monmouth.——An inspector for the State Board of Health was sent to Hull, White County, August 28, where an epidemic of smallpox was reported.

Personal.—Dr. William C. Clarke, Cairo, has resigned his position as chief health inspector.——Dr. William A. Balcke, Cropsey, has returned from Bloomington, where he underwent an operation for appendicitis.——Dr. W. R. Hamilton, an aged physician of Peoria, was knocked down by a buggy and seriously injured, August 30.

Hospital Notes.—The hospital fund for Taylorville Hospital now amounts to more than $2,300.——The Misses Alice and Caroline Graham, Washington, D. C., formerly residents of Canton, propose to furnish the necessary grounds and to erect a public hospital building thereon at Canton, to cost about $15,000, and containing about twenty rooms, under the condition that an endowment of $20,000 shall be provided, that the hospital shall be free to all schools of medicine, and that at least five rooms shall be available for charity patients.

Illegal Practice.—John Pattie, Peoria, who was found guilty of practicing medicine without a license and fined $100 and costs, has appealed from the decision of the court, claiming that he practiced under the special direction of a licensed physician.——Dr. James M. Fernan, a "Quaker medicine man," known as Brother Paul, who is under indictment at Freeport under fourteen counts, five for selling drugs in violation of the state law, five for practicing medicine without a license from the State Board of Health, and four for selling medicines in the city without a license, has been found guilty and sentenced to pay fines with costs amounting to more than $2,000. Brother Paul has left town.

Chicago.

Personal.—Dr. Casey Wood has returned from Europe.——Dr. Louis L. McArthur has gone to attend the International Surgical Congress at Brussels.

Corner-stone Laid.—The corner-stone of the new Washington Park Hospital, Vincennes Avenue, was laid September 4. Among the speakers were Professor Mauritzon of Augustana College and Rev. A. J. Lofgren. The building will cost $50,000 and is expected to accommodate 105 patients. Dr. Carl O. Young is physician to the institution.

Deaths of the Week.—There was a reduction in the annual death rate, as compared with the week previous, from 14.68 per 1,000 to 13.25 per 1,000. The total number of deaths was 510. Of these 130 were due to acute intestinal diseases, 63 to consumption, 40 to violence, including suicide, 37 to heart diseases, 30 to Bright's disease, and 22 each to pneumonia and cancer.

August Mortality.—During August 2,436 deaths were reported, equivalent to a death rate of 14.31 per 1,000. The death rate for August, 1904, was 12.90, and that for July, 1905, 13.48 per 1,000. Of the deaths 727 were of infants under 1 year, and 246 of children between 1 and 5 years. Among the causes of death were: Acute intestinal diseases, 638; consumption, 224; violence, including suicide, 210; heart diseases, 153; Bright's disease, 149; pneumonia, 119, and cancer, 111.

INDIANA.

State Board Enjoined.—The State Board of Medical Examination and Registration has been temporarily enjoined from revoking the license of Dr. John Milton Rhodes, Indianapolis, who is charged with gross immorality.

Fined.—Dr. Albert E. Sterne, Indianapolis, was fined $25 and costs, August 1, for exceeding the speed limit with his automobile.——Dr. Joseph A. Hallanan, Logansport, was found guilty of assault and battery July 29, and fined $25 and costs.

Medical School for Purdue.—At the meeting of the trustees of the Purdue University, held September 1 in Indianapolis, the university accepted the gift of the Medical College of Indiana, which has a property value of $100,000. The college will not be moved to Indianapolis, but will continue its work as a part of the university.

Appointments.—The newly appointed Board of Health of Jeffersonville, of which Drs. David C. Peyton and William H. Sheets, Jeffersonville, are the medical members, has organized and elected Dr. Sheets secretary.——Dr. Mary L. Widdop, Indianapolis, has been made a member of the medical staff at the Indiana State Soldiers' Home, Marion.——Dr. William S. Walker has been elected secretary of the school board of Lafayette.——Dr. William R. Cravens, Bloomfield, has been elected surgeon to the Illinois Central Railroad.

Ill and Injured.—Dr. James N. Hurty, secretary of the State Board of Health, is confined to his bed with lumbago.——Dr. Percy E. Terry, Rochester, is reported to be critically ill.——Dr. Rufus F. Blount, Wabash, fell down the stairs leading to his office August 25, fracturing his clavicle.——Dr. Arthur W. Tucker, Logansport, was operated on for appendicitis August 20.——Dr. Omer P. Phares, Liberty, fell down stairs August 7 and sprained his ankle.——Dr. Seymour C. Wilcox, New Albany, is reported to be critically ill.

Abroad and at Home.—Dr. Charles E. Barnett, Fort Wayne, will start for Europe early in October.——Dr. David E. Mattison, Marion, sailed for Europe August 20.——Dr. James E. Johnson, Marion, has returned from Europe.——Drs. Thomas W. Moorhead, Myron A. Boor, Joseph H. Weinstein and Leo J. Weinstein, Terre Haute, have returned from an extended trip to Europe.——Dr. Austin Funk, New Albany, leaves for Europe this month.——Dr. Frank A. Morrison, Indianapolis, returned July 27 after five months in Europe.——Dr. David R. Ulmer, Alexandria, is in Scotland.——Dr. William F. Clevenger, Indianapolis, returned from Europe July 28.

Sickness and Deaths in July.—The deaths in July numbered 2,774, and in the same month last year 2,772. Diarrheal diseases were reported as more prevalent and the deaths from this cause numbered respectively 361 and 296, an increase this year over last of 21.9 per cent. Almost 80 per cent. of all diarrheal troubles occur in infants and very old persons. The deaths from preventable causes were: Consumption, 321; typhoid fever, 62; diphtheria, 16; whooping cough, 23; pneumonia, 63; cerebrospinal meningitis, 32; influenza, 6; puerperal fever, 9; violence, 174, and smallpox, 3. The cancer deaths numbered 110, or 6 fewer than in July of 1904. The deaths under 5 years of age numbered 791, or 29 per cent. of the total, and the deaths 65 years of age and over numbered 592, or 21.9 per cent. of the total. The consumption mortality was less than in July, 1904. Of the 321 deaths from this cause 229, or 71.3 per cent. of the decedents, were between the ages of 15 and 50. Only 20 cases of smallpox with 3 deaths in 7 counties were reported. In July, 1904, there were 114 cases, with 5 deaths in 21 counties.

KENTUCKY.

Did Not Report Fever.—For failure to report a case of scarlet fever Dr. David A. Coyle, Lexington, was fined $25 and costs August 22.

Typhoid Epidemic.—An epidemic of typhoid fever is reported at Vine Grove.——There have been reported more than 50 cases of typhoid at Clay. The epidemic is now said to be under control.

Diphtheria.—Diphtheria is so prevalent in Elmsville and Harvieland, Franklin County, that the county board of health has prohibited all public gatherings.——Diphtheria is prevalent in Owensboro.

Personal.—Dr. Thomas E. Moss, Woodville, sailed from Seattle August 31 for the Philippine Islands.——Dr. William T. Leachman, Louisville, who has been in bad health for several months, has been taken to Martinsville, Ind.

LOUISIANA.

Stricken by Fever.—Drs. James T. Wolfe, New Orleans, and Louis A. Mereaux, St. Bernard, were stricken by yellow fever August 30.

Premedical Course.—The authorities of the Louisiana State University have decided to establish a premedical course, beginning in 1906.

Clinic for Women and Children.—The New Orleans Dispensary has been established at 1824 Annunciation Street for the purpose of giving free medical aid to poor women and children. Dr. Sara T. Mayo is in charge of the enterprise.

Personal.—Dr. D. N. Fletcher, Poland, was thrown from his horse, fracturing his arm near the elbow.——Dr. Thomas H. Watkins has been elected secretary of the Lake Charles Board of Health, vice Dr. Melvin F. Howe, resigned.

MARYLAND.

Baltimore Personals.—Dr. Eugene F. Cordell has resigned the position of editor of the *Hospital Bulletin* of the University of Maryland.——Dr. Charles F. Blake is critically ill with typhoid fever.——Dr. Emily Petersen has gone to Minnesota for several weeks.

Health Report.—The weekly report of the Baltimore health department for the week ended September 2 shows but 5 deaths from typhoid fever, although 143 cases of the disease were reported. For the entire month of August the following figures are here given: Deaths, 875; births, 915; deaths under 5 years of age, 361; deaths from typhoid fever, 34; cases reported of same, 324; mortality from Bright's disease increased from 36 in August, 1904, to 69.

Crisfield Marine Hospital.—A meeting was held in the Crisfield opera-house last week in the interest of the General Marine Hospital of that city, Dr. Jacob F. Somers presiding. The hospital is intended for poor sailors, who are brought there during the winter and are dependent on the charity of the place. The Woman's Christian Temperance Union has the work in charge and has almost enough money in hand to begin with. Among the directors are the state comptroller, Drs. Gordon T. Atkinson and W. F. Hall. Crisfield is one of the greatest centers of the Chesapeake oyster industry.

[illegible]—The question of legislation governin[illegible] ies is being discussed by the Baltim[illegible], the state's attorney and the coroners. At present undertakers are allowed to embalm bodies prior to the issuance of death certificates by attending physicians, and it is consequently possible for a crime to be committed and for the perpetrator to go undetected, since arsenic and bichlorid of mercury enter largely into the fluids used. Dr. C. Hampson Jones suggests the creation of the office of state chemist, whose duty it should be to be ready at all times to make an analysis.

MASSACHUSETTS.

Bequests.—By the will of the late Dr. Louis A. Prefontaine there is devised to Mercy Hospital, Springfield, a powerful magnet, and $5,000 to be applied on the indebtedness of the institution.

Medical Frauds Denied Use of Mails.—Fraud orders have been issued against J. Tige, S. Ray, Amos Ball & Co., Dr. Charles C. Rothfuchs, Dr. Longest and Dr. Herrick Medical Co., all of Boston.

Will Build Leper Hospital.—The State Board of Charity has purchased the island of Penikese, in Buzzard's Bay, and a leper hospital will be constructed there. It is expected the building will be ready for occupancy in the autumn.

Typhoid in Worcester.—At the present time there are more than 40 cases of typhoid fever in Worcester and four deaths have occurred, caused by milk supplied by a single milkman, who has been forbidden by the Board of Health to sell any more milk.

Personal.—Dr. Maurice H. Richardson, Boston, has gone to Brussels to attend the International Surgical Congress.——Dr. Henri T. Gabowry, Taunton, was thrown from his buggy August 29 and sustained a slight fracture of the base of the skull.——Dr. William F. Whitney, Boston, has succeeded the late Dr. Edward S. Wood as expert on blood.

MISSOURI.

Personal.—Dr. Franz J. T. Specht, physician in charge of the North Side Dispensary, St. Louis, has resigned.

Low Death Rate.—The death rate for St. Louis for July is reported to have been at the rate of 16.39 per 1,000. During the month 887 deaths were reported, 277 of which, or 31.2 per cent. of the total, were in children under 5 years.

Expected No Deaths.—In the construction of the new City Hospital, St. Louis, it was recently discovered that no provision had been made for a dead house, and ground has been broken for the construction of this relatively important department of the hospital.

Illegal Medical Practice.—H. H. Morris, an osteopath, who has been practicing osteopathy at Marshall without a license, has pleaded guilty and thrown himself on the leniency of the court. The penalty provided ranges from $50 to $500.——Dr. B. H. Westfall, arrested at Craig, charged with being an itinerant vender of drugs and nostrums without a license, was fined $5 and costs at Oregon.

Hospital Notes.—The St. Louis Skin and Cancer Hospital, which has been established through the influence of the charitable women of the city, has opened its new building at Jefferson avenue and St. Charles street.——About 360 patients, lame, halt, blind and victims of disease or accident, have been moved from the old City Hospital into the new building recently completed.——Arrangements have been made to equip a room in the new Salvation Army Hall, Webb City, for a dispensary for injured miners.——The Knox County General Hospital, Rockland, was formally opened August 14.——A new Emergency Hospital for St. Joseph is now completed and ready for occupancy.——On August 21 the Kansas City Council voted an appropriation of $150,000 from the hospital fund to be used in the construction of a new general hospital.

NEBRASKA.

Hospital Site Bought.—A large new site has been purchased for the Clarkson Memorial Hospital, Omaha, at Twenty-first and Howard Streets.

Asked to Cease Practice.—Dr. George A. Angus, Lincoln, who was charged with cheating during his examination before the State Board of Medical Examiners, has been notified to cease practice, pending a rehearing of his case.

Peculiar Decision.—The Supreme Court holds that the State Electro-Medical Institute of Omaha can not be licensed to practice medicine as a corporation, but that, as a corporation, it may make contracts with physicians to do business and may collect for the services thus rendered.

Personal.—Dr. John K. Maxson, Lincoln, was committed to the Nebraska Hospital for the Insane, Lincoln, August 29.——Dr. Sidney S. Wilson, Nebraska City, is spending the summer in Europe——Dr. F. H. Redmond, Tecumseh, has been appointed ward physician in the incurable ward of the State Hospital at Osawatomie, Kan.——Dr. Edwin W. Cook, Plattsmouth, has been appointed head physician, for Nebraska, of the Modern Woodmen of America——The residence of Dr. Ulysses S. Ammerman, Reynolds, was totally destroyed by fire, August 26. The loss is about $2,000, with no insurance.——Dr. James W. B. Smith, Albion, has been appointed assistant surgeon, N. G., Neb., with the rank of first lieutenant, and has been assigned to the Second Infantry.

NEW YORK.

Permit Refused.—Thomas F. O'Brien, Buffalo, against whom a "no bill" was returned by a grand jury on the charge of violating the tenement laws, applied to the health department for a permit to run a lodging house and was denied.

Fraud Order Issued.—A fraud order has at last been issued by the government against the New York Institute of Physicians and Surgeons and "Prof." Thomas E. Adkins, its president, of Rochester. They advertised in newspapers and magazines extensively of their wonderful "vitopathic" cures (?).

All Bids Rejected.—The board of award of the Treasury Department, which has been examining the bids for the construction of the Marine Hospital to be built in Buffalo, has just reached the decision to report in favor of the rejection of all the bids. At present the Marine Hospital patients are being cared for by contract at the new Niagara Hospital.

Buffalo Personals.—Dr. Roswell Park has subscribed $1.000 for the formation of a school of liberal arts at the University of Buffalo, and Dr. Edward Clark $100 for the same purpose.——Dr. Benjamin G. Long has returned from the Pacific Coast.——Dr. Monroe Manges has returned from Atlantic City.——

Dr. Irving P. Lyon returned from a month's stay in the Adirondacks.——Dr. Allen A. Jones has returned from the coast of Maine.——Dr. Ray H. Johnson is taking a trip up the lakes.——Dr. Lawrence G. Hanley has resigned from the civil service board.

Fair for German Hospital.—A gift fair for the benefit of the German Hospital is to be held in the fall. Arrangements are being made on a large scale and it is expected not only that the entire indebtedness of the hospital will be paid, but that sufficient cash will be forthcoming to erect nurses' quarters and a new wing for private wards.——At a recent meeting of the medical staff sufficient was subscribed to pay for a team and ambulance.

New York City.

Bequests.—The German Hospital, Brooklyn, has received a bequest of $5,059.87 from the estate of Christopher Kunzel, deceased, and one of $1,000 from the estate of the late Mrs. Julie Achelis.

Laboratory Almost Ready.—The new laboratory of the Health Department at the foot of East Sixteenth Street, which has been in process of construction for a long time, will be ready for occupancy in a few days.

Personal.—Dr. Albert H. Ward, retiring house surgeon of St. Catherine's Hospital, Brooklyn, on leaving the hospital was given a dinner, at which he was presented with a case of surgical instruments.——Dr. Henry A. Baker, New York City, has been made medical director of the Washington Life Insurance Company.

OHIO.

Donations.—John M. Niles has presented to the Champaign Sanitarium his property, valued at $75,000, retaining a life interest in the estate.——The floral festival recently held in Van Wert netted $2,000 to the Van Wert County Hospital.

Hospital Notes.—Dr. William J. Gillette has erected a hospital in Toledo to accommodate 75 patients, which he expects will be ready early in the spring.——Delaware County Hospital, at Delaware, which is now almost complete, will be ready to receive patients early next month.

New Medical Society.—The physicians of Wellsville and East Liverpool have organized a society to be known as the Wellsville and East Liverpool Academy of Medicine. Dr. William M. Calhoun, East Liverpool, was elected president, and Dr. Arthur B. Holland, Wellsville, secretary.

Personal.—Dr. William H. Kanauss, Newark, who was accidentally shot while at target practice last May, has retired from personal work, as he has not yet fully recovered from the effect of the wound.——Dr. Louis L. Syman, Springfield, has resigned as a member of the hospital staff and has been succeeded by Dr. Wallace Ort.

The Afflicted.—Dr. D. B. Van Buren Burkett, Columbus, who was seriously injured a few weeks ago in a street car accident, is convalescent and will soon resume practice.——Dr. Arthur E. Hobson, Flushing, sprained his ankle in jumping from his buggy August 10.——Dr. Lewis J. Feid, Cincinnati, was thrown from his buggy in a runaway accident August 20 and painfully bruised.——Dr. William H. Booth, Salem, is seriously ill with typhoid fever at Lakeside.——Dr. Charles E. Reese, Lancaster, was thrown from his buggy in a runaway accident August 19 and seriously injured.——Dr. John A. Wright, Toledo, was seriously injured by the overturning of his buggy August 24, sustaining bad cuts and bruises.——Dr. Jerome Bland, Bucyrus, is in a serious condition from a recent cerebral hemorrhage.

OREGON.

Medium Fined.—On July 29, Judge Cameron found Louis Schlessinger, Portland, a medium who was accused of practicing medicine without a license, guilty, and fined him $75.

New Building for Medical Department.—Plans have been completed for the erection of a $15,000 building for the medical department of Willamette University, Salem. The building will be of brick and three stories high.

Health Board Changes.—The Mayor of Portland, Dr. Harry Lane, has appointed Drs. Esther C. Pohl, Andrew J. Giesy and George F. Wilson as members of the Medical Board of Health, succeeding Drs. Mae H. Cardwell, William Jones and James F. Bell.

Surgery Dedicated.—A new surgical department for the Good Samaritan Hospital, Portland, was dedicated August 8. Bishop B. Wistar Morris presided, and Drs. Simeon E. Josephi and George F. Wilson delivered addresses. The surgical equipment was presented to the hospital by members of the Couch family at the cost of several thousand dollars.

PENNSYLVANIA.

Philadelphia.

Will Study Cholera.—Dr. Fairfax Irwin, chief of the United States Public Health and Marine-Hospital Service in this city, and chief of the Reedy Island and Delaware Breakwater quarantine stations, has been ordered to Hamburg, Germany, to study the cholera situation.

Bequests.—By the will of Hannah Burgess, St. Mary's Hospital will receive $300.——By the will of Thomas Woolman, the Frankford Insane Asylum receives $2,000; Red Bank Sanitarium Association, $1,000, and the Children's Country Week Association, $1,000.——By the will of Louisa Baumann each of the following institutions receives $1,000: German Hospital. Orphans' Home of Germantown, and the Philadelphia Home for Incurables.

Personal.—Dr. E. J. Beardsley sailed for Europe on the *Friesland*, September 2.——Dr. Francis D. Patterson has been appointed examining physician of the State Constabulary.——Dr. Joseph Roberts, Camden, N. J., has been appointed skiagrapher in St. Joseph's Hospital, vice Dr. Flynn, resigned.——Dr. John Stanton has been appointed assistant chief of the out-patient nose and throat department of the Children's Hospital.——Dr. J. L. Harkness has been appointed chief of the laryngological department of Jefferson Hospital.

Health Report.—The deaths from all causes during the week aggregated 437, or one less than the number reported the three previous weeks, a coincidence never before known in the health bureau's history. For the same period of last year the deaths numbered 371. There is a decided decrease in contagious diseases, particularly typhoid fever. The principal causes of death were as follows: Typhoid fever, 15; diphtheria, 5; whooping cough, 7; consumption, 41; apoplexy, 20; heart disease, 25; acute respiratory diseases, 29; enteritis (under 2 years), 45; enteritis (over 2 years), 9; Bright's disease, 36; appendicitis, 4; injuries, 13; suicides, 5. There were 117 cases of contagious disease reported, with 20 deaths, as compared with 142 cases and 15 deaths for last week. The deaths from typhoid fever numbered 15, an increase of 5 over those of last week. There were 62 cases reported during the week, as compared with 82 cases the previous week, and 125 three weeks ago.

UTAH.

State Hospital Changes.—Dr. David H. N. Calder has been appointed medical superintendent of the State Mental Hospital, Provo, vice Dr. Milton H. Hardy, removed——Dr. Frederick Clift, Heber, has been appointed assistant medical superintendent of the State Mental Hospital, Provo.

Hospital Notes.—The White Cross Sanitarium and State Emergency Hospital has been established in Salt Lake City, at 253 S.W. Temple St.——A building permit has been issued for a brick addition to the Dr. Groves Latter Day Saints Hospital at Salt Lake City, to cost $10,000.

Personal.—Dr. John S. Gordan, Ogden, has been appointed physician of Weber County, vice Dr. Harry B. Forbes——Dr. Charles F. Wilcox, Salt Lake City, was struck over the eye by a horseshoe thrown by a boy and suffered an extensive scalp wound——Dr. Chauncey M. Benedict, Salt Lake City, has been reappointed assistant surgeon general of the National Guard of Utah.

VERMONT.

Personal.—Dr. Marcello Hutchinson, superintendent of the State Hospital for the Insane, Waterbury, has been seriously ill with nephritis, but is now improving.——Dr. Charles L. Ervin, Newport Center, has been appointed trustee of the State Asylum for the Insane at Waterbury.

Hospital Officers Elected.—At the annual meeting of the St. Alban's Hospital Association the following officers were elected: Vice-president, Dr. Theodore R. Waugh; secretary and clerk, Dr. E. I. Brown, and managers of the institution, Drs. Theodore R. Waugh and Dr. Stephen W. Paige.

Impure Food.—The State Board of Health has been investigating the food products for sale there, making 118 tests. Of 38 samples of maple sugar and syrup, 5 were adulterated: 2 samples of oysters had boric-acid preservatives; 12 out of 15 samples of lemon extract were impure, 3 containing coal-tar dyes; other adulterated products were, vanilla extract, baking powder and ginger champagne.

Dedication of College.—The dedication of the new medical college building of the University of Vermont, Burlington, took place June 27. The building was presented to the Board of Trustees by Dr. Henry C. Tinkham, dean of the medical department and chairman of the building committee. The building was accepted in behalf of the Board of Trustees by Mathew H. Buckham, president of the University. A history of the medical department was then given by Dr. J. H. Woodward, class of 1882, New York City.

VIRGINIA.

Hospital Notes.—Mrs. Thomas F. Ryan will shortly begin the erection of a hospital in Lynchburg, three stories high and fireproof throughout, to cost $100,000——A new story has been added to St. Luke's Hospital, Richmond.——The Dunlop Memorial Hospital, Petersburg, which has just been completed and is now ready for use, was erected by Mrs. Mary Corling Dunlop in memory of her husband, the late David Dunlop—— The new King's Daughter Hospital, Staunton, erected at a cost of $20,000, was dedicated July 1.

Personal.—Dr. Stuart McGuire, Richmond, has been made president of the University College of Medicine, vice Dr. Allison Hodges, resigned——Dr. Robert H. Whitehead of the medical department of the University of North Carolina, Chapel Hill, has been elected professor of anatomy and dean of the University of Virginia Medical Department, Charlottesville—— Dr. Joseph M. Burke, Petersburg, has been appointed general surgeon of the Seaboard Air Line——Dr. Edward L. W. Ferry, Miller's Tavern, was injured in a runaway accident, August 6, sustaining a fracture of the jaw.

GENERAL.

Plague at Panama.—A case of plague which terminated fatally is reported from La Boca.

Cholera in Manila.—Eleven new cases of cholera have been reported from Manila. The total number of cases since the outbreak is reported as forty, with twenty-five deaths.

Quarantine Against Panama.—The president of Nicaragua has issued a proclamation declaring the ports of that country closed to all vessels from Panama because of reports of the presence of bubonic plague in the latter republic.

New York and New England Association of Railway Surgeons.—The fifteenth annual meeting of this association will be held at the Academy of Medicine, New York City, Nov. 17-18, 1905, under the presidency of Dr. G. P. Conn, of Concord, N. H. One-half day of the meeting will be devoted to a symposium on "Injuries to the Head and Spine."

Mississippi Valley Medical Association.—At the next meeting of the Mississippi Valley Medical Association, to be held at Indianapolis, Ind., October 10-12, the annual addresses will be delivered by Dr. Arthur R. Edwards, Chicago, on "Certain Phases of Uremia, Their Diagnosis and Treatment," and by Dr. W. D. Haggard, Nashville, Tenn., on "The Present Status of Surgery of the Stomach."

Pacific Coast Surgeons Meet.—At the third annual meeting of the Pacific Association of Railway Surgeons, San Francisco, August 17, the following officers were elected: President, Dr. Thomas W. Huntington, San Francisco; vice-presidents, Drs. Thomas C. McCleave, Berkeley, Cal., and William O. Spencer, Huntington, Ore.; Secretary, Dr. James P. Dunn, Oakland, Cal., and treasurer, Dr. Frank L. Adams, Oakland.

Seaboard Air Line Surgeons Meet.—Surgeons of the Seaboard Air Line recently met in annual convention at Old Point Comfort, Va., and elected the following officers: President, Dr. Gottlob A. Neuffer, Abbeville, S. C.; vice-presidents, Drs. W. C. Monroe, Sanford, Fla., Gray G. Holladay, Portsmouth, Va., and Jarrett W. Palmer, Ailey, Ga.; and chairman of executive committee, Dr. Southgate Leigh, Norfolk, Va. The 1906 meeting will be held in Savannah, Ga.

American Roentgen Ray Society.—The sixth annual meeting of the American Roentgen Ray Society will be held at the Johns Hopkins Hospital, Baltimore, September 28-30. The Stafford Hotel has been selected as headquarters. The program includes papers by foreign as well as by American workers in this special department of medicine. All regular practitioners are eligible to membership in the society and are invited to attend the scientific sessions and to view the exhibition of apparatus. Further information can be obtained from the secretary, Dr. Russell H. Boggs, Empire Building, Pittsburg, Pa.

Cumberland Valley Medical Association.—At the third annual meeting of this association held at Mount Holly Park, Md., the following officers were elected: President, Major James Evelyn Pilcher, M.D., Carlisle, Pa.; vice-presidents, David F. Unber, Mercersburg, Pa., Augustus C. Maisch, Hagerstown, Md., and George C. Borst, Newville, Pa.; secretary, Dr. John J. Coffman, Scotland, Pa.; assistant secretaries, Drs. Philip R. Koons, Mechanicsburg, Pa., Henry C. Devilbiss, Chambersburg, Pa., and DeWitt C. R. Miller, Mason and Dixon, Pa.; and treasurer, Dr. John J. Koser, Shippensburg, Pa. Major Pilcher presented a memoir on the "Medical Lessons in the Far East," in which he illustrated by the success of the Japanese medical department, the importance of state medicine and of the active participation of physicians in public affairs. At the annual banquet Major Pilcher presided as toastmaster.

Postal War on Medical Pretenders.—According to the Philadelphia *Record*, the postal authorities are attempting to rid Philadelphia of "quack" doctors, fake medical men, etc. On August 28 over a score of persons "who have been advertising in a manner which the authorities consider objectionable were summoned to the postoffice to identify themselves before they could secure mail addressed to them." All the visitors were questioned by the postal inspectors and warned against carrying on their business through the medium of the mails. The position of most of them is such that the federal authorities can take no legal steps, because no overt act has been committed of which the authorities have any knowledge. Several of those summoned had written very plain letters, ostensibly to some woman, but really to the inspectors, offering to perform an illegal operation for a special price; but it is necessary to show that an operation was performed in consequence of the writing of the letter. The empty promise to commit a prohibited act for pay does not constitute a crime. According to the *Record*, publications which have been printing the offending advertisements were also notified by the postal authorities that they must cease publishing them or suffer prosecution.

THE YELLOW FEVER SITUATION.

Louisiana.—The situation among the fishing settlements in Jefferson parish has become very bad.——On the sugar plantations the disease still [illegible] are being modified.——During the w[illegible] cases have been reported: Havelona [illegible] son, 16, 2 deaths; Port Barrow, 2; St. Rose, 19; Amelia, 12 and 1 death; Bayou Bœuf, 9; Houma, 2; Ardoyni, 3; Kenner, 19, 2 deaths; Hanson City, 13, 1 death; St. Bernard, 7; Point La Hoche, 2; Pecan Grove, 8, 1 death; Belmont, 1; Elizabeth, 1, 4 deaths; Donaldsonville, 4; St. Gabriel, 1; Alexandria, 1; Smoke Bend, 2; Shaffer plantation, 30; [illegible]endale, 1; Belle Grove, 6; Terrebonne parish, 2, 1 death; Riverside (to August 31), 134, 5 deaths; Leeville (to September 1), 321, 29 deaths; La Place, 7.——Dr. Milton F. Smith, health officer at Shreveport, writes that only three cases have occurred there, with one death. All the patients came from New Orleans and were held in detention.

New Orleans.—Surgeon White has ordered compulsory fumigation of houses, including those whose occupants are out of the city.——As a step to educate the public and in addition to lectures, the city newspapers have reprinted in full the medical papers recounting the steps in the discovery of mosquito conveyance.——The federal officers on August 22 decided to put a quietus on Dr. Leach and the arsenic fad. It was published that he had, in 1890, urged arsenization for yellow fever, cholera and bubonic plague. Surgeon-General Sternberg's unfavorable report was reprinted.. Further, Surgeon White showed that arsenized persons were then under treatment for yellow fever. This proved to be too much for Dr. Leach, who beat a retreat to Minnesota, bewailing his "unfair treatment." It is estimated that up to August 22 some 7,000,000 arsenic tablets "prepared under the direction of Dr. Reginald Leach, arsenical expert," had been taken by New Orleans people in the last two weeks. Just before he left his supports voted to aid the federal service in all its work, thus closing the arsenic incident.——The Orleans Paris Medical Society has issued and distributed an attractive and practical pamphlet addressed to physicians, trained nurses and others entrusted with the care of yellow fever cases.——New Orleans people who have been away on vacations are now freely returning.——Dr. J. T. Wolff and Dr. L. A. Meroux have the fever.——All the authorities on September 1 joined in signed statements that the crisis was past and the fight won.——On September 2 there were but 29 new cases, with 3 deaths. Total cases to September 3, 2,037; total deaths to September 3, 294; death rate, 14.4 per cent.——Dr. Philip Berge was arrested September 2 for failure to report 2 cases of yellow fever.——Surgeon White has joined with the New Orleans Medical Society in asking that moving day be postponed from September 1 to October 1.

Other States.

Arkansas.—Governor Jefferson Davis annulled the permits and certificates of health issued by the State Board of Health, ordered that no attention be paid to any sort of certificate of health, ordered that no railroad crews cross the boundary line from Louisiana, and refused to permit Dr. Goldberger of the United States Public Health and Marine-Hospital Service to pass by rail over a few miles of Arkansas territory on an errand of mercy to another point in Louisiana. Dr. G. M. D. Cantrell, president; Dr. R. B. Christian, secretary, and Drs. W. H. Miller and W. B. Hughes at once resigned from the State Board of Health.

Florida.—Three cases, all among Greeks, of yellow fever were announced at Pensacola on August 29. Up to September 2, 8 cases had been found there, and there had been one death.

Illinois.—In the Springfield *Register* of August 25 Secretary Egan of the State Board of Health was quoted as pronouncing as "an unmitigated lie" the story of a case of yellow fever at Brownsville.——A car of 35 Paducah residents from Chicago is said to have been held in Cairo, locked in the car, for a number of hours.

Kentucky.—Paducah has not yet defied the State Board of Health by quarantining, but has appointed a train inspector and has ordered that only the health officer may give certificates of health.

Mississippi.—The Greek who died at Gregory, Mo., of yellow fever was but recently arrived from Natchez, Miss., but on August 21 Natchez assured the world that "there has not been the slightest suspicion of yellow fever here since 1898." Yet on August 27 cases were reported from Natchez, the report denied by the health officer on August 27, and on August 29 Surgeon Wasdin, Marine-Hospital Service, positively diagnosed 9 cases and noted 5 suspects. Since then 2 additional cases have been reported.——Dr. John Guiteras on August 30 made a positive diagnosis of yellow fever in two white persons, neither of whom, it is said, had been out of Vicksburg for two months, and both of whom were within the protection of a close shotgun quarantine. Five more were found in the next two days.——Gulfport, which for the last time on August 21 announced that it had no cases of the fever, has since reported 16 cases, all occurring within quarantine.——Mississippi City was visited August 13 by Dr. Sanders and Dr. Mohr of the Alabama health board, who thought they found a suspicious case. Surgeon Wasdin saw the patient a day later and said it was not yellow fever, but a local physician asked him to see another case which was yellow fever, and then others were unearthed. As in some other places, the cases were so mild that they easily escaped diagnosis.——The Mississippi state notification law is simple and effective if enforced, providing $50 fine and ninety days in jail (the statutory penalty for a misdemeanor) for any physician who fails immediately to notify the secretary of the State Board of Health of any case of yellow fever, cholera, dengue, smallpox, or any other virulent epidemic contagious disease.——Governor Vardaman on September 1 commenced the work of the Marine-Hospital Service and asked for its help at Natchez and Vicksburg. He also has recently recommended more rational quarantines, especially not to restrict movement of freight. His general attitude has become decidedly helpful.

Oklahoma and Indian Territories.—On August 26 the state quarantined against Louisiana.——Indian Territory fears it has a case of yellow fever at Maysville.

Pennsylvania.—Dr. Thomas J. Mays, Philadelphia, had a letter in the New York *Sun* of August 29 calling the mosquito etiology of yellow fever "one of the most disastrous of medical errors," and writing of "the presumptuousness of the germ theory."

Tennessee.—Memphis was much aroused by Surgeon White's report that a Memphis woman fell ill with yellow fever on the day of her arrival in New Orleans. Quarantines against Memphis followed. Governor Vardaman of Mississippi and Secretary Hunter of the state health board went to Memphis to investigate. Charges against Surgeon White were threatened, but the date on the Memphis health certificate held by the patient appeared fully to substantiate Dr. White's conclusion.——Governor Cox notified the quarantine officials of Grand Junction, in Hardeman County, not to interfere with transfer of passengers from train to train, telling them he would send militia there if the interference continued.——The inspection service on trains in and out of Chattanooga has been assumed by the United States Public Health and Marine-Hospital Service at the request of the State Board of Health. ——Memphis had a sensational flare-up over apparent conflict of authority between the police and the health officer, which appeared as a misunderstanding and which resulted in the health officer keeping his own inspectors.——Governor Cox on September 1 sounded the governors of southern states as to a conference on immigration and quarantine.

Texas.—The state quarantine office at Beaumont has been closed.——The Mexican border is closely watched.——The banks are not taking up the deficiency bonds offered by the state health officer.

FOREIGN.

Russian Red Cross.—The Russian Red Cross has spent about $11,000,000 in the course of the present war. During July the total expenses of its various hospitals were only $150,000, but they are much higher after a battle.

Asiatic Cholera in Prussia.—Cholera seems to be spreading in West Prussia. Twenty-two cases and six deaths are reported. Twelve sanitary stations have been established along the Weichsel river, and the Prussian government is sending physicians from other ports of Germany to assist the local health authorities.

International Congress of Anatomy.—The first International Congress of Anatomy was held recently at Geneva. The following anatomic societies took part: The anatomic societies of Great Britain and Ireland, the German *Anatomische Gesellschaft*, the Association of American Anatomists, the *Unione Zoologica Italiana*, and the French *Association des Anatomistes*. Nearly 200 individuals attended. The scientific proceedings were of great interest. The next meeting will be held at Bordeaux, France, at Easter, 1906, under the presidency of Professor Viault.

Pharmacology

Secrecy.—Whatever is secret is suspicious; this especially applies to medicines.

Patent and Secret Proprietary Medicines.—Some weeks ago we published a letter from Mr. Bok of the *Ladies' Home Journal* in which he appealed to physicians for aid in the fight against patent medicines. Since then some correspondence has passed between Mr. Bok and the Editor of The Journal. The last letter received was accompanied with a number of advertisements clipped from medical journals—and we regret to say some were from The Journal of the American Medical Association, one of which is still there and probably will be till the contract expires—with a query, "What is the difference between these and 'patent medicines'?" No reply has been sent, as we are not able to answer. If any of our readers can tell the difference between most of the secret proprietary medicines that are advertised to physicians in medical journals and patent medicines that are advertised to the public in newspapers, we hope they will inform us so that we can reply to the editor of the *Ladies' Home Journal*.

Reading Pages for Sale.—The following is a copy of a letter in our possession, the original of which was sent to a manufacturing pharmaceutical firm by a monthly medical journal, which is supposed to be up to the average at least in its ethical conduct. It shows clearly the *Deus ex machina* in the administration of certain medical journals:

> Gentlemen:—We hope this letter will induce you to place a special contract for our special June issue, which is to be issued in honor of the Portland meeting of the American Medical Association. This issue will have a circulation of 12,000 copies, and will be read by the best men in the profession.
>
> You should take a page or two pages for a special advertisement of your ————. The cost for one page is $25, for two pages $40. *Should you place a contract for this issue we shall publish a three-hundred-word report in your interest in our reading columns.* We know it would be to your advantage to be in a special issue that will reach the leading men of the profession.
>
> We trust you will be with us, and thanking you for the courtesy of an early reply, we beg to remain,
>
> Yours sincerely,

Official Carlsruhe Warning Against Irregular Practices.—THE JOURNAL has mentioned from time to time the official notices published by the municipal authorities of Carlsruhe warning the public against certain irregular practitioners and against proprietary medicines, etc., which are advertised in the local press or on the billboards. The list includes a number of American nostrums. The instigator of the warnings is the *Stadrath* or mayor, who is earning the encomiums of all interested in protecting the public health and pocket. He has recently had all the warnings collected and published in a booklet of 148 pages, which is offered for sale by the publishing house of G. Braun, Carlsruhe. The *Deutsche med. Wochft.* suggests that this booklet deserves a place on the table in the waiting room of every physician. It will bear translating into all languages, as many of the nostrums it describes are advertised in all civilized countries.

The Control of Proprietary Remedies.—A serious attempt is being made by the Council of Pharmacy and Chemistry of the American Medical Association to control the various secret remedies which are put before the medical profession in that country. The following particulars of the scheme are taken from a copy of the rules for which we are indebted to the courtesy of a well-known firm of druggists. It appears that in the United States of America there is a rapidly growing sentiment against the increasing legion of secret preparations. THE JOURNAL of the American Medical Association conceived the idea of forming a board of control, to be composed of pharmacists and chemists, which should pass in review all medicinal preparations offered for insertion in the advertising pages of that journal. That idea has been modified by making the functions of the proposed board similar to those of the Committee of Revision of the United States Pharmacopeia. The work is to be taken up where that committee left off, and a description of the unofficial preparations which conform to the required standard will be published in the form of a book to be entitled "New and Unofficial Remedies." In other words, it will form an extra pharmacopeia, giving useful details of reputable preparations. The board of trustees of the American Medical Association has authorized the formation of an advisory board, to be known as the Council of Pharmacy and Chemistry, to carry out the work. The council is composed of men eminent in medicine and pharmacy as writers, teachers and research workers. The Council proposes immediately to examine into the composition of the various medical preparations that are offered to physicians, and are not included in the United States Pharmacopeia or in other standard text-books or formularies. In the rules here given the term "article" is applied to any drug or preparation used in the treatment of disease.

(Here follow the Rules of the Council.)

The manufacturers of legitimate preparations have nothing to fear from this action on the part of the American Medical Association. On the contrary, they are to be congratulated that the Association has undertaken to separate the wheat from the chaff. In this country, medical practitioners are overwhelmed with samples and literature of preparations which may be good, bad or indifferent. The composition is not usually disclosed and the habit is formed of throwing all aside, the good and the bad together. The list of unofficial preparations of known compositions and strength when published by the American Medical Association should prove valuable to the medical profession and a safeguard to the public. Measures of similar character might with advantage be adopted in this country. It should not be difficult to find funds for the purpose, especially if a working arrangement were made with the American Medical Association whereby each country should investigate its own products to avoid covering the same ground twice.

Though the rules adopted by the American Medical Association are good and worthy of imitation, they are not sufficiently comprehensive to nullify entirely the present system which leads to self-drugging. The weak points are not hard to find. Let it be imagined that a practitioner prescribes a preparation which is labeled on the lines laid down in the rules as follows: "A hypnotic and sedative, containing three-quarters of a grain of morphin in 110 minims. Dose 5 to 30 minims." Unless the practitioner initials and dates the prescription whenever he requires it to be repeated there is nothing to prevent the repetition of the prescription dozens and even hundreds of times. Pharmacists should be requested to consider it a breach of etiquette to copy a prescription for a patient or to make it up for any other person. Again, it should be a rule that no proprietary medicine should be delivered to the patient in the original package in order to prevent the purchase of further supplies without a prescription. The excellent rules of the American Medical Association should therefore be supplemented by further rules for the guidance of pharmacists on these points touching the repetition of prescriptions and the transference of medicines from original packages before delivery to the patient. A set of rules of this kind, supplemented by a more complete code of pharmaceutical etiquette, would benefit alike the public and the medical profession and should find a place in the system of medico-pharmaceutical ethics.

Again, it is obvious that another weak point in the proposed scheme is that it will almost of necessity fail to touch the very class of secret or proprietary remedies which are productive of the largest amount of self-drugging—viz., so-called "patent" medicines produced for the express purpose of appealing to the credulity of the multitude. Since the proposed list is rightly intended solely for the use of medical men the failure to secure recognition will hardly be of any material detriment to the sale of such preparations which will still be advertised in the lay journals and reach the public for whom their proprietors cater.—(Editorial, *The Lancet*, Aug. 12, 1905.)

[*The Lancet* is correct in its last paragraph. The patent-medicine evil should be assailed, but the proprietary nostrum must first be eradicated. Before we can proclaim war on patent medicines, with energy and with a clear conscience, it will be necessary for us as physicians to rid ourselves of the proprietary nostrum evil by ceasing to prescribe preparations that are nothing more nor less than patent medicines. Before medical journals can criticize newspapers for carrying patent-medicine advertisements, they must themselves refuse advertisements of similar preparations, even though these be dignified with the name of proprietary medicines. THE JOURNAL of the American Medical Association itself is not yet entirely free from this reproach, but it is freeing itself as rapidly as undesirable contracts expire.—ED.]

Correspondence

The Construction of the Panama Canal, a Sanitary Problem.

ANN ARBOR, MICH., Aug. 31, 1905.

To the Editor:—In view of the fact that yellow fever is prevalent in Panama, and in view of the statement that more than 60 per cent. of the people in the Canal Zone are now infected with malaria, and in view of the report of the presence of the plague on the isthmus, it seems unnecessary to argue that the method followed by this government up to the present time, in the construction of the canal, has not been characterized by wisdom. Please permit me to offer the following statements, which, in a condensed way, represent my views concerning the means that should be adopted in the carrying out of this great enterprise. These suggestions I have hurriedly condensed and will state as follows:

1. The first thing that should be done is to render the Canal Zone a habitable place. That this has not been done, although we have been in possession for more than two years, must be admitted by all.

2. The engineering problem involved in the construction of the Panama canal is of secondary importance compared with the sanitary problem which must be met.

3. The French failed to complete the canal, not because they had not the engineering ability necessary to do it, but because they were wholly unable to cope with the insanitary conditions existing in that locality.

4. In converting the Canal Zone into a habitable location, engineering skill must be employed, but it will be only

Other States.

Arkansas.—Governor Jefferson Davis annulled the permits and certificates of health issued by the State Board of Health, ordered that no attention be paid to any sort of certificate of health, ordered that no railroad crews cross the boundary line from Louisiana, and refused to permit Dr. Goldberger of the United States Public Health and Marine-Hospital Service to pass by rail over a few miles of Arkansas territory on an errand of mercy to another point in Louisiana. Dr. G. M. D. Cantrell, president; Dr. R. B. Christian, secretary, and Drs. W. H. Miller and W. B. Hughes at once resigned from the State Board of Health.

Florida.—Three cases, all among Greeks, of yellow fever were announced at Pensacola on August 29. Up to September 2, 8 cases had been found there, and there had been one death.

Illinois.—In the Springfield *Register* of August 25 Secretary Egan of the State Board of Health was quoted as pronouncing as "an unmitigated lie" the story of a case of yellow fever at Brownsville.——A car of 35 Paducah residents from Chicago is said to have been held in Cairo, locked in the car, for a number of hours.

Kentucky.—Paducah has not yet defied the State Board of Health by quarantining, but has appointed a train inspector and has ordered that only the health officer may give certificates of health.

Mississippi.—The Greek who died at Gregory, Mo., of yellow fever was but recently arrived from Natchez, Miss., but on August 21 Natchez assured the world that "there has not been the slightest suspicion of yellow fever here since 1898." Yet on August 27 cases were reported from Natchez, the report denied by the health officer on August 27, and on August 29 Surgeon Wasdin, Marine-Hospital Service, positively diagnosed 9 cases and noted 5 suspects. Since then 2 additional cases have been reported.——Dr. John Guiteras on August 30 made a positive diagnosis of yellow fever in two white persons, neither of whom, it is said, had been out of Vicksburg for two months, and both of whom were within the protection of a close shotgun quarantine. Five more were found in the next two days.——Gulfport, which for the last time on August 21 announced that it had no cases of the fever, has since reported 16 cases, all occurring within quarantine.——Mississippi City was visited August 13 by Dr. Sanders and Dr. Mohr of the Alabama health board, who thought they found a suspicious case. Surgeon Wasdin saw the patient a day later and said it was not yellow fever, but a local physician asked him to see another case which was yellow fever, and then others were unearthed. As in some other places, the cases were so mild that they easily escaped diagnosis.——The Mississippi state notification law is simple and effective if enforced, providing $50 fine and ninety days in jail (the statutory penalty for a misdemeanor) for any physician who fails immediately to notify the secretary of the State Board of Health of any case of yellow fever, cholera, dengue, smallpox, or any other virulent epidemic contagious disease.——Governor Vardaman on September 1 commenced the work of the Marine-Hospital Service and asked for its help at Natchez and Vicksburg. He also has recently recommended more rational quarantines, especially not to restrict movement of freight. His general attitude has become decidedly helpful.

Oklahoma and Indian Territories.—On August 26 the state quarantined against Louisiana.——Indian Territory fears it has a case of yellow fever at Maysville.

Pennsylvania.—Dr. Thomas J. Mays, Philadelphia, had a letter in the New York *Sun* of August 29 calling the mosquito etiology of yellow fever "one of the most disastrous of medical errors." and writing of "the presumptuousness of the germ theory."

Tennessee.—Memphis was much aroused by Surgeon White's report that a Memphis woman fell ill with yellow fever on the day of her arrival in New Orleans. Quarantines against Memphis followed. Governor Vardaman of Mississippi and Secretary Hunter of the state health board went to Memphis to investigate. Charges against Surgeon White were threatened, but the date on the Memphis health certificate held by the patient appeared fully to substantiate Dr. White's conclusion.——Governor Cox notified the quarantine officials of Grand Junction, in Hardeman County, not to interfere with transfer of passengers from train to train, telling them he would send militia there if the interference continued.——The inspection service on trains in and out of Chattanooga has been assumed by the United States Public Health and Marine-Hospital Service at the request of the State Board of Health.——Memphis had a sensational flare-up over apparent conflict of authority between the police and the health officer, which appeared as a misunderstanding and which resulted in the health officer keeping his own inspectors.——Governor Cox on September 1 sounded the governors of southern states as to a conference on immigration and quarantine.

Texas.—The state quarantine office at Beaumont has been closed.——The Mexican border is closely watched.——The banks are not taking up the deficiency bonds offered by the state health officer.

Official Carlsruhe Warning Against Irregular Practices.—The Journal has mentioned from time to time the official notices published by the municipal authorities of Carlsruhe warning the public against certain irregular practitioners and against proprietary medicines, etc., which are advertised in the local press or on the billboards. The list includes a number of American nostrums. The instigator of the warnings is the *Stadrath* or mayor, who is earning the encomiums of all interested in protecting the public health and pocket. He has recently had all the warnings collected and published in a booklet of 148 pages, which is offered for sale by the publishing house of G. Braun, Carlsruhe. The *Deutsche med. Wochft.* suggests that this booklet deserves a place on the table in the waiting room of every physician. It will bear translating into all languages, as many of the nostrums it describes are advertised in all civilized countries.

The Control of Proprietary Remedies.—A serious attempt is being made by the Council of Pharmacy and Chemistry of the American Medical Association to control the various secret remedies which are put before the medical profession in that country. The following particulars of the scheme are taken from a copy of the rules for which we are indebted to the courtesy of a well-known firm of druggists. It appears that in the United States of America there is a rapidly growing sentiment against the increasing legion of secret preparations. The Journal of the American Medical Association conceived the idea of forming a board of control, to be composed of pharmacists and chemists, which should pass in review all medicinal preparations offered for insertion in the advertising pages of that journal. That idea has been modified by making the functions of the proposed board similar to those of the Committee of Revision of the United States Pharmacopeia. The work is to be taken up where that committee left off, and a description of the unofficial preparations which conform to the required standard will be published in the form of a book to be entitled "New and Unofficial Remedies." In other words, it will form an extra pharmacopeia, giving useful details of reputable preparations. The board of trustees of the American Medical Association has authorized the formation of an advisory board, to be known as the Council of Pharmacy and Chemistry, to carry out the work. The council is composed of men eminent in medicine and pharmacy as writers, teachers and research workers. The Council proposes immediately to examine into the composition of the various medical preparations that are offered to physicians, and are not included in the United States Pharmacopeia or in other standard text-books or formularies. In the rules here given the term "article" is applied to any drug or preparation used in the treatment of disease.

(Here follow the Rules of the Council.)

The manufacturers of legitimate preparations have nothing to fear from this action on the part of the American Medical Association. On the contrary, they are to be congratulated that the Association has undertaken to separate the wheat from the chaff. In this country, medical practitioners are overwhelmed with samples and literature of preparations which may be good, bad or indifferent. The composition is not usually disclosed and the habit is formed of throwing all aside, the good and the bad together. The list of unofficial preparations of known compositions and strength when published by the American Medical Association should prove valuable to the medical profession and a safeguard to the public. Measures of similar character might with advantage be adopted in this country. It should not be difficult to find funds for the purpose, especially if a working arrangement were made with the American Medical Association whereby each country should investigate its own products to avoid covering the same ground twice.

Though the rules adopted by the American Medical Association are good and worthy of imitation, they are not sufficiently comprehensive to nullify entirely the present system, which leads to self-drugging. The weak points are not hard to find. Let it be imagined that a practitioner prescribes a preparation which is labeled on the lines laid down in the rules as follows: "A hypnotic and sedative, containing three-quarters of a grain of morphin in 110 minims. Dose 5 to 30 minims." Unless the practitioner initials and dates the prescription whenever he requires it to be repeated there is nothing to prevent the repetition of the prescription dozens and even hundreds of times. Pharmacists should be requested to consider it a breach of etiquette to copy a prescription for a patient or to make it up for any other person. Again, it should be a rule that no proprietary medicine should be delivered to the patient in the original package in order to prevent the purchase of further supplies without a prescription. The excellent rules of the American Medical Association should therefore be supplemented by further rules for the guidance of pharmacists on these points touching the repetition of prescriptions and the transference of medicines from original packages before delivery to the patient. A set of rules of this kind, supplemented by a more complete code of pharmaceutical etiquette, would benefit alike the public and the medical profession and should find a place in the system of medico-pharmaceutical ethics.

Again, it is obvious that another weak point in the proposed scheme is that it will almost of necessity fail to touch the very class of secret or proprietary remedies which are productive of the largest amount of self-drugging—viz., so-called "patent" medicines produced for the express purpose of appealing to the credulity of the multitude. Since the proposed list is rightly intended solely for the use of medical men the failure to secure recognition will hardly be of any material detriment to the sale of such preparations which will still be advertised in the lay journals and reach the public for whom their proprietors cater.—(Editorial, *The Lancet*, Aug. 12, 1905.)

[*The Lancet* is correct in its last paragraph. The patent-medicine evil should be assailed, but the proprietary nostrum must first be eradicated. Before we can proclaim war on patent medicines, with energy and with a clear conscience, it will be necessary for us as physicians to rid ourselves of the proprietary nostrum evil by ceasing to prescribe prepations that are nothing more nor less than patent medicines. Before medical journals can criticize newspapers for carrying patent-medicine advertisements, they must themselves refuse advertisements of similar preparations, even though these be dignified with the name of proprietary medicines. The Journal of the American Medical Association itself is not yet entirely free from this reproach, but it is freeing itself as rapidly as undesirable contracts expire.—Ed.]

Correspondence

The Construction of the Panama Canal, a Sanitary Problem.

Ann Arbor, Mich., Aug. 31, 1905.

To the Editor:—In view of the fact that yellow fever is prevalent in Panama, and in view of the statement that more than 60 per cent. of the people in the Canal Zone are now infected with malaria, and in view of the report of the presence of the plague on the isthmus, it seems unnecessary to argue that the method followed by this government up to the present time, in the construction of the canal, has not been characterized by wisdom. Please permit me to offer the following statements, which, in a condensed way, represent my views concerning the means that should be adopted in the carrying out of this great enterprise. These suggestions I have hurriedly condensed and will state as follows:

1. The first thing that should be done is to render the Canal Zone a habitable place. That this has not been done, although we have been in possession for more than two years, must be admitted by all.

2. The engineering problem involved in the construction of the Panama canal is of secondary importance compared with the sanitary problem which must be met.

3. The French failed to complete the canal, not because they had not the engineering ability necessary to do it, but because they were wholly unable to cope with the insanitary conditions existing in that locality.

4. In converting the Canal Zone into a habitable location, engineering skill must be employed, but it will be only a

Ernest Pierpont, M.D. Chicago Medical College, 1880, an old resident of the Ojal Valley, Cal., died at his home, Overlook, Nordhoff, August 26, aged 50.

John Van Dermark. M.D. Illinois, 1883, died at his home in Rosendale, N. Y., August 24, from typhoid fever, after an illness of one week, aged 57.

Henry F. Garey, M.D. Washington University School of Medicine, Baltimore, 1876, of Kansas City, Mo., died at Baltimore August 31, from nephritis.

John J. Lawrence, M.D. New York University, New York City, 1861, died at his home near Coakley, N. C., from dropsy, August 21, aged 68.

J. Y. Hicks, M.D. Tulane University of Louisiana, New Orleans, 1852, died at his home in Moulton, Texas, aged 23.

Abroad.

Christopher Heath, F.R.C.S. Death has suddenly removed one of the most prominent of London surgeons and teachers, Mr. Christopher Heath. Born in London in 1835, he was the grandson of Mr. John Heath, a surgeon in the Royal Navy, was educated at King's College School and Hospital, receiving his M.R.C.S. degree in 1856. He served as a surgeon with the Baltic fleet in the Crimean war. In 1856 he was appointed demonstrator of anatomy at Westminster Hospital and in 1862 lecturer on anatomy and assistant surgeon. In 1866 he became assistant surgeon and teacher of operative surgery at University College Hospital, and in 1875 he was made surgeon and professor of surgery. While at the Westminister Hospital he wrote his well-known "Practical Anatomy," which reached a ninth edition in 1902. A year after his appointment to University College Hospital he was awarded the Jacksonian prize for his essay on "The Injuries and Diseases of the Jaws, Including Those of the Antrum with the Treatment by Operation or Otherwise." In 1881 he was elected a member of the Council of the Royal College of Surgeons, and in 1895 president. He was an admirable teacher, being always clear and practical, as many popular works which emanated from his pen show. Among the best known are his "Course of Operative Surgery," and his "Manual of Minor Surgery and Bandaging," which ran into twelve editions. He also edited his standard "Dictionary of Practical Surgery." In 1897 he delivered the Lane Medical Lectures at the Cooper Medical College in San Francisco, which were listened to with great attention, not only by the students, but by hundreds of practitioners from the Pacific coast. A pupil of Sir William Ferguson, Mr. Heath was a bold and successful operator. As an authority on the surgical diseases of the jaws he was foremost. He was a keen controversialist and a hard hitter. He died suddenly at his residence in London, August 8, aged 70.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

DETERIORATION OF APOMORPHIN HYDROCHLORATE.

Dodge City, Kansas, Aug. 22, 1905.

To the Editor:—Anent your observation on apomorphin, in reply to an inquirer in The Journal of August 19, page 548, I beg to say that H. C. Wood, in the tenth edition of his work on "Therapeutics," merely mentioned the discolorations, as also does H. H. Rusby in his article on the drug in Wood's "Reference Handbook." Gould's "Students' Dictionary" does not mention it, but Lippincott's "Medical Dictionary"—late revision—condemns the use of the discolored material.

Some four years ago I had occasion to use apomorphin in a case of acute alcoholism, and injected the discolored tablets with good results. I stuck the tube in my pocket hypo and had no occasion to use it again till last week, when, on responding to a hurry call, I found a man who had swallowed a half ounce of laudanum, and was already profoundly under the influence. My heart misgave me when I pulled out that old green tube: it was clear that the man could not be made to swallow anything, and that a stomach-tube was a useless piece of furniture. To have gone to the drug store to search for a tube of fresh tablets would have consumed valuable time; so I hurriedly injected 1/6 gr. of the discolored drug into the patient's arm without waiting for any sort of cleansing, and in about three minutes he was giving a lively exhibition of reverse peristalsis of the stomach to the delight of a highly interested audience and doubly to the relief of the attending physician. No untoward symptoms developed.

Since reading your condemnation of the discolored article, I have replaced my green tablets with white ones in a brown tube: although I can not avoid the suspicion, on account of the favorable result above described, that I have allowed myself to be euchred out of my fifteen cents.

W. H. Graves.

PRODUCTION OF SYNTHETIC PROTEIDS.

Nutley, N. J., Aug. 22, 1905.

To the Editor:—Is there, in English, any volume embodying the work of L. v. Fisher and others in the laboratory production of synthetic proteids? Where can I obtain information as to these, their variety and character and methods of production? Haeckel says: "Chemists have hitherto tried in vain to master the chemical structure of these obscure protein compounds," meaning, particularly, the various albumins. Are any of these included with some sugars and urea, etc., as laboratory products?

Joseph Clements.

Answer.—Details concerning the synthetic preparation of proteid-like substances, involving principles and methods discovered by Kossel, Curtius, Fischer and others, are not described in English books on chemistry. The chemistry of proteids, insofar as it is understood to-day, is treated of in Otto Cohnheim's "Chemie der Eiweisskörper," a second edition of which has appeared recently. Unfortunately, this is not translated into English.

TEST FOR URIC ACID.

Houston, Texas, Aug. 26, 1905.

To the Editor:—Please give me a quick and easy method for estimating the percentage of uric acid in urine. W. A. H.

Answer.—A very convenient and fairly exact method is the one in which Ruhemann's uricometer is used. The tube is filled up to certain marks with carbon disulphid, and then with a solution containing iodin 1.5 grams, potassium iodid 1.5 grams and absolute alcohol 15 grams in 185 c.c. of distilled water. On adding a certain amount of urine and shaking, the carbon disulphid will become of a dark brown copper color: with more urine the carbon disulphid will absorb all free iodin and the mixture will look like urine. The adding of urine should be stopped as soon as the carbon disulphid shows only a slight reddish tint, because this will disappear entirely after repeated shakings. The test is finished when the indicator appears snow-white, a sign that all iodin has been neutralized by the urine. After the foam has settled, the proportion of uric acid is read off on the scale.

ACONITIN.

Ashton, S. Dak., Aug. 28, 1905.

To the Editor:—A number of text-books state that aconitin should not be used internally, yet at the same time stating that it has the same physiologic action as aconite. Will you state why it should not be used, if it should not be? Has it the same physiologic action as aconite? Are there reliable preparations for internal use to be had? J. M. Crabb.

Answer.—Aconitin is used internally. It is the most potent of all vegetable alkaloids. In the U. S. Pharmacopeia (8th dec. rev.) the dose is given as 1/400 gr. (0.00015). It has practically the same action as aconite, but must be used cautiously and in minute doses.

State Boards of Registration

COMING EXAMINATIONS.

Massachusetts Board of Registration in Medicine, State House, Boston, September 12-13. Secretary, E. B. Harvey, Boston.

Central District Indian Territory Board of Medical Examiners, South McAlester, October 2. Secretary, W. B. Caldwell, Hugo.

Utah State Board of Medical Examiners, Salt Lake City, October 2. Secretary, R. W. Fisher, Salt Lake City.

Board of Medical Examiners of Arizona, Phoenix, October 2-3. Secretary, A. Martin, Phoenix.

Idaho State Board of Medical Examiners, Boise, October 3. Secretary, J. L. Conant, Jr., Genesee.

Indiana Board of Medical Registration and Examination, State House, Indianapolis, October 3. Secretary, W. T. Gott, Crawfordsville.

Board of Medical Examiners of Montana, The Capitol, Helena, October 3. Secretary, W. C. Riddell, Helena

North Dakota State Medical Examining Board, Grand Forks, October 3. Secretary, H. M. Wheeler, Grand Forks.

Minnesota State Board of Medical Examiners, Old Capitol Building, St. Paul, October 3-5. Secretary, C. J. Ringnell, Minneapolis.

Rhode Island State Board of Health, State House, Providence, October 5-6. Secretary, G. T. Swarts, Providence.

Regular Board of Medical Examiners of Georgia, The Capitol, Atlanta, October 9. Secretary, F. D. Paterson, Cuthbert.

Michigan State Board of Registration in Medicine, Capitol Building, Lansing, October 10. Secretary, B. D. Harison, Sault Ste. Marie.

State Medical Board of the Arkansas Medical Society, Little Rock, October 10. Secretary, J. P. Runyan, Little Rock.

State Board of Medical Registration of Vermont, Y. M. C. A. Hall, Burlington, October 10-12. Secretary, W. S. Naya, Underhill.

Kansas State Board of Medical Registration and Examination, State House, Topeka, October 10-11. Secretary, G. F. Johnston, Lakin.

Board of Medical Supervisors of Washington, D. C., Washington, D. C., October 12. Secretary, W. C. Woodward, Washington, D. C

Board of Medical Examiners of State of Texas, San Antonio, October 17. Secretary, T. T. Jackson, San Antonio.

State Board of Medical Examiners of New Jersey, Trenton, October 17-18. Secretary, E. L. B. Godfrey, Camden.

State Board of Health of Illinois, The Great Northern Hotel, Chicago, October 18. Secretary, J. A. Eagan, Springfield.

Louisiana State Board, New Orleans, October 20-21. Secretary, F. A. Larue, New Orleans.

Arizona July Report.—Dr. Ancil Martin, secretary of the Board of Medical Examiners of Arizona, reports the written examination held at Phoenix, July 4-5, 1905. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 8, all of whom passed.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending September 2, 1905:

Shook, Jay R., asst.-surgeon, left Fort Des Moines, Iowa, with Troop 'G,' 11th Cavalry, to Terre Haute, Ind., and return.

Billingslea, C. C., asst.-surgeon, reported for temporary duty at Fort D. A. Russell, Wyo., from Fort Riley, Kans.

Siler, Joseph F., asst. surgeon, left Fort Meade, S. Dakota, with 6th Cavalry on field duty.

Bourke, James, asst.-surgeon, granted two months and twenty-eight days' leave of absence when his services can be spared, with permission to go beyond the sea.

Baker, Frank C., asst.-surgeon, ordered, on completion of competition at Sea Girt, N. J., to return to his proper station, Presidio of Monterey, Cal.

Quinton, W. W., asst.-surgeon, left Fort McPherson, Ga., en route to Fort Barrancas, Fla., on detached duty.

Bernheim, J. R., dental surgeon, left San Francisco, Cal., en route to Fort Slocum, N. Y., for duty.

Coffey, A. McD., contract surgeon, left Fort Lawton, Wash., and arrived at Fort Davis, Alaska, for duty.

Byars, C. R., contract surgeon, left Fort Sam Houston, Tex., and arrived at Fort Sill, Okla. Ter., for temporary duty with Provisional Regiment of Field Artillery.

Halliday, Francis A., contract surgeon, relieved from temporary duty at Fort Caswell, N. C., and further duty at Fort McPherson, Ga., and ordered to Fort Fremont, S. C., for duty.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending September 2, 1905.

McCormick, A. M. D., surgeon, detached from the *Hartford* and ordered home to wait orders.

Brister, J. M., P. A. surgeon, detached from the *Atlanta* and ordered home to wait orders.

Riggs, R. E., asst.-surgeon, detached from the *Newark* and ordered home to wait orders.

Byrnes, J. C., surgeon, detached from the *Texas* and ordered to the Naval Academy.

Freeman, G. F., P. A. surgeon, detached from the Naval Station, Olongapo, P. I., and ordered to the Naval Station, Cavite, P. I.

Taylor, J. S., P. [illegible] from the *Ohio* and ordered to duty at the Un[illegible]kin, China.

Wickes, G. L., [illegible] from the Naval Station, Cavite, P. I., and [illegible]

Pryor, J. C., surgeon, ordered to the Naval Medical School, Washington, D. C.

Dunn, H. A., P. A. surgeon, detached from the *Terror* and ordered home to wait orders.

Hathaway, G. S., asst.-surgeon, ordered to the Naval Hospital, Washington, D. C.

Geiger, A. J., asst.-surgeon, detached from the *Severn*, granted leave for thirty days, and then to wait orders.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Aug. 30, 1905:

Sawtelle, H. W., surgeon, to proceed to Richmond, Va., for special temporary duty.

Magruder, G. M., surgeon, granted leave of absence for one month from Aug. 26, 1905, on account of sickness.

Gardner, C. H., P. A. surgeon, to proceed to New Orleans, La., and report to Surgeon J. H. White for special temporary duty.

Foster, M. H., P. A. surgeon, to proceed to Galveston, Texas, and assume temporary command of the service.

Stiles, Ch. W., Chief, Division of Zoology, granted leave of absence for twelve days from Aug. 14, 1905.

Hunt, Reid, Chief, Division of Pharmacology, granted leave of absence for ten days from Aug. 21, 1905.

Hunt, Reid, Chief, Division of Pharmacology, to represent service at meeting of American Pharmaceutical Association at Atlantic City, N. J., September 4-9, 1905.

Richardson, N. D., acting asst.-surgeon, granted leave of absence for seven days from Aug. 17, 1905.

Stevenson, J. W., acting asst.-surgeon, to report at Washington, D. C., for special temporary duty.

Thompson, C. V., acting asst.-surgeon, granted leave of absence for sixteen days from Sept. 2, 1905.

Richardson, S. W., pharmacist, to report at Washington, D. C., for special temporary duty.

McKay, M., pharmacist, relieved from duty at Boston, Mass., and directed to proceed to Cincinnati, Ohio, and report to acting asst.-surgeon in charge for duty and assignment to quarters.

Woods, C. H., pharmacist, on being relieved from duty at Cincinnati, Ohio, to proceed to Evansville, Ind., and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist G. I. Van Ness, Jr.

Carlton, C. G., pharmacist, granted leave of absence for seven days from Aug. 22, 1905.

Van Ness, G. I., pharmacist, leave of absence for thirty days from Aug. 1, 1905, granted Pharmacist Van Ness by Department letter of July 19, 1905, amended so that said leave shall be for nineteen days only.

Van Ness, G. I., Jr., pharmacist, on being relieved from duty at Evansville, Ind., by Pharmacist C. H. Woods, to report at Washington, D. C., for duty.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General Public Health and Marine-Hospital Service, during the week ended August 19, 1905:

SMALLPOX—UNITED STATES.

Arkansas: Fort Smith, May 20-June 3, 2 cases.

California: Los Angeles, August 5-12, 5 cases; San Francisco, August 12-19, 2 cases.

District of Columbia: Washington, August 12-19, 2 cases.

Florida: Jacksonville, August 12-19, 1 case.

Illinois: Chicago, August 12-19, 2 cases, 2 deaths.

Louisiana: New Orleans, August 12-19, 1 case, imported.

Massachusetts: Lowell, August 12-19, 1 case.

Ohio: Canton, March 1-April 2, 1 case.

Wisconsin: Appleton, August 11-18, 4 cases; Milwaukee, July 30-August 12, 2 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, June 17-24, 1 case.

SMALLPOX—FOREIGN.

Africa: Cape Town, July 8-15, 5 cases.

Brazil: Bahia, July 15-22, 1 death; Rio de Janeiro, July 16-23, 21 cases, 1 death; Rio Grande de Sul, July 11, epidemic.

France: Paris, August 4-11, 17 cases, 7 deaths.

Great Britain: Cardiff, Aug. 6-12, 2 cases; Newcastle-on-Tyne, July 29-August 5, 1 case.

India: Bombay, July 11-25, 1 death; Calcutta, July 15-22, 2 deaths; Karachi, July 15-23, 1 case, 1 death; Madras, July 8-21, 8 deaths.

Mexico: City of Mexico, July 15-August 12, 23 cases, 18 deaths.

Panama: Bocas del Toro, July 22-28, 1 case.

Russia: Odessa, July 30-August 5, 9 cases, 2 deaths; St. Petersburg, July 15-29, 5 cases, 3 deaths.

Spain: Barcelona, July 21-August 10, 7 deaths.

Turkey: Constantinople, July 23-August 6, 7 deaths.

YELLOW FEVER—UNITED STATES.

Louisiana: Ascension Parish, to August 14, 1 case, 1 death; Avoyells Parish, 1 case, 1 death; Caddo Parish, 4 cases; Calcasieu Parish, 3 cases, 2 deaths; East Carroll Parish, 1 case, 1 death; Iberville Parish, 1 case, 1 death; Jefferson Parish, 5 cases, 5 deaths; Lafourche Parish, 3 cases, 1 death; Madison Parish, 2 cases, 1 death; Orleans Parish, July 21-Aug. 17, 1,129 cases, 165 deaths; Plaquemines Parish, to August 14, 11 cases, 2 deaths; Rapides Parish, 2 cases; St. Charles Parish, to August 15, about 18 cases, 3 deaths; St. James Parish, 1 case; St. John Parish, to Aug. 14, about 12 cases, 2 deaths; St. Mary Parish, 48 cases, 3 deaths; Terrebonne Parish, 2 cases, 1 death.

YELLOW FEVER—FOREIGN.

Mississippi: Mississippi City, to August 17, 10 cases.

Brazil: Rio de Janeiro, July 16-22, 20 cases, 7 deaths.

Guatemala: Livingston, July 22-August 5, 4 deaths; Zacapa, August 5, present.

Honduras: Chamelicon, August 10, present; Choloma, present; Puerto Cortez, July 22-28, 2 cases, Aug. 3-10, 1 death.

Mexico: Tierra Blanca, Aug. 6-12, 2 cases, 1 death; Vera Cruz, 6 cases, 3 deaths.

CHOLERA.

India: Bombay, July 11-25, 2 deaths; Calcutta, July 15-22, 14 deaths; Madras, July 7-21, 33 cases.

PLAGUE—INSULAR.

Philippine Islands: Manila, June 17-24, 2 cases, 2 deaths; Cebu, 2 cases, 2 deaths.

PLAGUE—FOREIGN.

China: Hongkong, June 3-17, 47 cases, 47 deaths.

India: Bombay, July 11-25, 84 deaths; Calcutta, July 15-22, 10 deaths; Karachi, July 8-23, 18 cases, 15 deaths.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

The Reduction of Fever.

QUININ.

Aside from the hydrotherapeutic measures in the reduction of temperature Shoemaker, in *Med. Bull.*, regards quinin as the most effective agent in reducing temperature and that in periodical fevers, he states, it is a specific. It limits tissue change, checks fermentation, prevents putrefaction and inhibits the activity of infective germs and thus limits the production of heat. He does not advise it given in enormous doses, for in such large doses it is a gastrointestinal irritant and is injurious to Peyer's patches. He, therefore, recommends it in moderate doses as a tonic and as a reducer of temperature. In epidemic influenza it is of decided value. It counteracts the fever, sustains the strength, allays the cough, and is particularly valuable when the disease is complicated by bronchopneumonia. The fever of croupous pneumonia is likewise favorably influenced. In scarlatina and erysipelas this drug is one of the chief reliances.

SALICYLIC ACID.

Salicylic acid is of use in a number of febrile affections and especially in acute inflammatory rheumatism. Its purest form is obtained in oil of gaultheria. According to this author, salicylic acid is inferior to quinin in the reduction of fevers not of rheumatic origin, and in rheumatism it is surpassed by oil of gaultheria and salicin.

As a remedy for colds and rheumatic pains an infusion made from the leaves of the wintergreen is recommended. The pure oil is effective in doses ranging from 2 to 20 minims (.12 to 1.30). It possesses both antiseptic and antipyretic properties and quickly relieves pain of rheumatic origin when given in full doses every two hours in milk or enclosed in capsules. Its physiologic action is the same as that of salicylic acid and its toxic effects are much less than that of the artificial acid.

In scarlatina the author states that the oil of wintergreen forestalls the occurrence of arthritic complications which are liable to develop in this disease. It may be applied locally combined as follows:

℞. Olei gaultheriæ
Olei olivæ, āā........................ʒiv 15|
M. Sig.: Apply locally to the affected joints.

SALICIN.

Salicin, which is a principle akin to the salicylates and derived from the willow and poplar, is better borne by the stomach than either salicylic acid or the oil of gaultheria. It does not depress the heart, but, on the other hand, serves as a tonic. It can be given safely in doses of several drams daily, the usual dose being 10 grains (.65) every two or three hours. It should be given every hour until three or four doses have been given. It is of value in both the acute and chronic forms of rheumatism, also in the treatment of influenza. A combination of salicin and quinin is a good one in such cases. Salicin is also valuable in tuberculosis to subdue the hectic fever and to check the toxic diarrhea. It also improves the appetite and increases the digestive powers. In pelvic inflammations accompanied by febrile reaction, as in cases of salpingitis, oöphorites, metritis and peritonitis, it is valuable. In the rheumatic fevers of children it is especially to be recommended, as it is easily borne by them. It promotes more rapid convalescence and never produces delirium.

ALCOHOL.

Alcohol has some effect in reducing fever by diminishing tissue change and promoting heat radiation. It is not, however, given primarily to reduce temperature, but it is of value when fever is present, in some cases to quiet delirium and to promote sleep. Its administration, therefore, should depend on the condition of the patient. The malt liquors are frequently given during the stage of convalescence from fevers. In hemorrhagic measles or scarlatina, diphtheria and pneumonia, alcohol is demanded, and it is frequently of service in the treatment of erysipelas.

CAMPHOR.

Camphor, like alcohol, stimulates the heart and circulation in low fevers. It diminishes the production of heat and lessens tissue waste. It is of more benefit when given in small doses, as large quantities depress. Its virtue is too often overlooked, so states the author, while there is such a strong tendency at the present time to experiment with new drugs. This drug overcomes restlessness and excitement caused by high temperature. It is of value in typhoid fever and typhoid pneumonia, especially in aged individuals. It is also of value in the eruptive fevers and influenza.

ACONITE.

Aconite reduces fever by its effect on the circulation. It diminishes the action of the heart, decreases the frequency of the pulse rate and lowers blood pressure. It also promotes elimination by the skin and kidneys. It is of value, therefore, in the treatment of sthenic fevers, which not infrequently are seen in robust individuals. In typhoid fever it is of no service. In the eruptive fevers of childhood it produces good effect, also in acute inflammatory conditions, in pleurisy, pneumonia, pericarditis, endocarditis and tonsillitis, by promoting the elimination and reducing the temperature.

VERATRUM VIRIDE.

Veratrum viride allays the overactivity of the heart and reduces the tension of the pulse. It should not be prescribed in large doses, as they cause nausea and vomiting and sometimes are followed by collapse. It is contraindicated in typhoid fever unless violent delirium and a high tensioned pulse is present. In the beginning of the first stage of pneumonia it is very valuable. It may be given in from 10 to 15 minim (.65-1.00) doses of the tincture every two hours to reduce temperature and pulse rate. It is harmful in the second stage of pneumonia.

GELSEMIUM.

Gelsemium is another preparation which lowers the pulse rate and decreases arterial tension. It acts on the ganglia of the heart. This preparation also increases the activity of the skin and reduces fever. It should be given only in fevers of the sthenic type to allay the cerebral excitement, congestion and inflammation. It is sometimes recommended for this purpose in allaying the cerebral excitement, congestion and inflammation present in cerebrospinal meningitis. It is more serviceable in diseases of children. It is recommended by the author in beginning pneumonia and pleurisy and in remittent fever.

ANTIMONY.

Antimony acts by depressing the heart's action and is a diaphoretic. Tartar emetic is of value in acute bronchitis by reducing temperature and promoting secretion by the mucous membrane. It is very valuable in the treatment of tonsillitis and parotiditis. The coaltar products are mentioned by the author only to be condemned as a class of agents which produce grave influences on the heart and circulation in general. They depress the nervous system and in some cases produce collapse, cyanosis, dyspnea, vertigo and vomiting.

Corns.

Brocq, in an abstract in *Med. News*, recommends that the corn be softened at night with a piece of flannel covered with soap and spirits, followed by curetting it with a curette or a knife. Apply daily for six or eight days the following dressing:

℞.	Ext. cannabis ind. alc.	gr. viiss		50
	Acidi salicylici	gr. xv	1	
	Alcoholis	m. xv	1	
	Spts. etheris	ʒss	2	
	Collodii (flexible)	ʒiss	6	

M. Sig.: Apply locally once a day.

After the foregoing dressing has been applied for the required number of times the foot should be bathed in hot water and the corn curetted. Other methods consist in moistening the corn with a concentrated solution of salicylic acid in alcohol, covering it with pulverized salicylic acid and sealing with a piece of cotton. The dressing should be renewed in four or five days, and if inflammation is present the treatment should be stopped. About the eighth day the foot should be soaked in hot water and the corn can then be removed.

The following combination is regarded as valuable in the removal of corns:

℞.	Acidi salicylici	gr. xl	2	65
	Ext. cannabis ind.	gr. v		30
	Collodii flex. q. s. ad	℥i	30	

M. Sig.: To be painted over the corn once or twice daily for several days. Or:

℞.	Ext. cannabis ind.	gr. iii		20
	Acidi salicylici	ʒss	2	
	Olei terebinthinæ	m. xv	1	
	Acidi acetici glacial	m. vi		40
	Cocainæ (alk.)	gr. vi		40
	Collodii q. s. ad	ʒv	20	

M. Sig.: Apply a thin coating over corn every night until it drops off. Or:

℞.	Acidi salicylici	gr. x		65
	Ext. cannabis ind.	gr. iv		25
	Alcoholis			
	Etheris, āā	ʒss	2	
	Collodii	ʒiii	12	

M. Sig.: Apply locally. Or:

℞.	Potass. hydratis	gr. iii		20
	Tinct. iodi	ʒi	4	
	Glycerini	℥ss	15	
	Aquæ destil	℥i	30	

M. Sig.: Apply to the corn morning and night with a camel's hair brush.

Cystitis.

The following combination is recommended in the treatment of cystitis:

℞.	*Salol*	ʒii	8	
	Pulv. acaciæ q. s.			
	Aquæ cinnamomi	℥xii	360	

M. Ft. mistura. Sig.: One tablespoonful four times a day.

A suppository is sometimes necessary to relieve the accompanying pain:

℞.	Pulv. opii	gr. iv		25
	Ext. hyoscyami	gr. vi		40
	Ol. theobromæ q. s.			

M. Ft. sup. No. vi. Sig.: One suppository two or three times a day, if necessary, to relieve the pain.

Medicolegal

Privileged Communications.

Section 3163 of the Code of Civil Procedure of Montana, among other things, provides: "There are particular relations in which it is the policy of the law to encourage confidence and to preserve it inviolate; therefore, a person can not be examined as a witness in the following cases: . . . (4) A licensed physician or surgeon can not, without the consent of his patient, be examined in a civil action as to any information acquired in attending the patient which was necessary to enable him to prescribe or act for the patient." Most of the states in the union, if not all, the Supreme Court of Montana says, in the personal injury case of May vs. Northern Pacific Railway Co., have similar statutory provisions.

In the case before the court the plaintiff on her direct examination merely described her injury, and told of her treatment by two physicians. On cross-examination she admitted that a third physician had also attended her as her physician, and had treated her for the injury complained of; but she did not assume to detail any conversation had with him, or to tell of the character or extent of the treatment which he gave her. The defendant insisted that this physician should have been permitted to testify as to the condition of the plaintiff at the time he attended her as her physician. But the court does not think so.

Of course, says the court, if the patient calls the physician as a witness to testify, he thereby expressly consents to the proceeding, or, if he sits by and fails to object, he tacitly consents that the physician may testify. Furthermore, it has been held that where the patient directly attacks the physician, as by an action for damages for malpractice, he abandons the protection given by the statute, for he thereby challenges the physician to disprove the patient's contention as to the character of his injury or of the physician's treatment. Lane vs. Boicourt, 128 Ind. 420. It has also been held that where two or more physicians are employed at the same time, with respect to information gained at the same consultation, calling one of the physicians as a witness by the patient constitutes a waiver of the statutory prohibition as to the other or others (Morris vs. Railway Co., 148 N. Y. 88), although this doctrine is disputed by respectable authority (Baxter vs. Cedar Rapids, 103 Iowa, 599). Likewise it has been held that, where the patient calls the physician as a witness at one trial, this constitutes a waiver of the privileges as to that physician on a second trial of the same case. McKinney vs. Railroad Co., 104 N. Y. 352. But this doctrine has also been disputed in Burgess vs. Sims Drug Co., 114 Iowa, 275, and Grattan vs. Insurance Co., 92 N. Y. 274.

But so far as this court's investigation discloses, no court of last resort has ever held that the mere fact that the patient testifies generally concerning his condition constitutes a waiver of the privilege granted by the statute. In Marx vs. Railroad Co., 10 N. Y. Supp. 159, the Supreme Court of New York held that, where the patient assumes to tell all that took place between himself and the physician, this constitutes a waiver of the privilege; and in Treanor vs. Railroad Co., 16 N. Y. Supp. 536, decided by the Common Pleas Court of New York City, it was also held that, where the patient testifies without reservation as to his injuries and their effect on him, this likewise constitutes a waiver of the privilege. But these cases were later disapproved, and in effect directly overruled, by the Supreme Court of New York in Fox vs. Turnpike Co., 69 N. Y. Supp. 551, and Dunckle vs. McAllister, 74 N. Y. Supp. 902, and by the Court of Appeals of New York in Morris vs. Railway Co., above cited. In Highfill vs. Railroad Co., 93 Mo. App. 219, it is said that, where a patient goes on the stand and testifies as to what his physician found and said, he thereby waives the privilege under the statute. It may be safely said that the Missouri Appellate Court is now the only court asserting the doctrine announced by it, and even that case can hardly be a precedent in favor of the contention of the defendant here, for this plaintiff did not assume to tell what the third physician mentioned had done for her, or to detail any conversations with him, and her statement that he had been her physician was not a voluntary one, but was brought out on cross-examination.

It is not the inherent incompetency of the evidence that precludes it being given, but it is the fact that the evidence comes from a person who occupies a certain relation of confidence to the patient, by virtue of which the statute says he shall not disclose his information without the consent of the person from whom he gained it. So far as this court is aware, the authorities are uniform in holding against the contention of the defendant in this case. Williams vs. Johnson, 112 Ind. 273; Railroad Co. vs. Shepherd, 30 Ind. App. 193; Warsaw vs. Fisher, 24 Ind. App. 47; Green vs. Nebagamain, 113 Wis. 508; McConnell vs. City of Osage, 80 Iowa, 293; Baxter vs. Cedar Rapids, 103 Iowa, 599; Burgess vs. Sims Drug Co., 114 Iowa, 275; Butler vs. Railway Co., 30 Abb. N. C. 78, affirmed in 143 N. Y. 630; Mellor vs. Railway Co., 105 Mo. 455.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

August 26.

1 *Three Cases of Tumor of Spinal Cord Operated on with Good Result. J. C. Warren, Boston.
2 *What Action Should Be Taken to Suppress Smallpox? H. M. Bracken, Minneapolis, Minn.
3 *Nature and Cause of Hunger, Appetite and Anorexia. M. I. Knapp, New York.
4 Beriberi. J. L. McCool, Marcus Hook, Pa.
5 *To What Extent is Climate a Negligible Factor in the Treatment of Pulmonary Tuberculosis? W. L. Dunn, Asheville, N. C.
6 *Medical Treatment of Excessive Uric Acid in the Urine. B. Robinson, Chicago.

1. **Tumor of Spinal Cord Successfuly Operated On.**—Warren reports two cases of localized tumors of the spinal cord in which removal completely relieved the symptoms, and a third case in which operation was followed by marked improvement.

2. **Suppression of Smallpox.**—Bracken, in order to make the best report possible to the Conference of State and Provincial Boards of Health of North America on the best means of controlling smallpox, obtained from various public health officials, scientists and practitioners their opinions on this most important question, and uses these opinions as the basis for his arguments in favor of compulsory examination, at least of children, and against the indefinite continuance of quarantine as a means of suppressing smallpox. In conclusion he urges that the conference put itself on record as follows: Believing that all attempts to restrain smallpox by means of quarantine in a community not protected by vaccination will fail; that rigid quarantine in a well-vaccinated community is unnecessary; that attempts to control the spread of smallpox by means of quarantine is unscientific, irrational, unsuccessful and misleading; that in laying down strict rules for the quarantine of smallpox, sanitary authorities are favoring unscientific and illogical methods and are conveying false ideas as to safety, this conference protests against further attempts to control smallpox by means of quarantine and requests the passage of compulsory vaccination laws similar to those of Germany, requiring (1) the compulsory vaccination of infants, (2) revaccination at puberty. The conference should further place itself on record as requesting that steps be taken to secure a safe and efficient vaccine, and that vaccination be carried out by official vaccinators acting under the authority of the various boards of health; also that steps be taken to secure a vaccine the quality and efficiency of which are beyond question. Legislators and the people should be advised as to their responsibilities in suppressing smallpox, and a time should be set for the total abandonment of quarantine as a means of attempting to control this disease.

3. **Nature and Cause of Hunger, Appetite, and Anorexia.**—Knapp says that hunger is a lesser degree of pain, produced by the contraction of the muscularis either of the pylorus or of the entire stomach or of the duodenum, or of the contraction of the muscularis of all these structures. If the contraction is more intense, it is felt as a painful hunger. If the contraction is of a slight degree, it is evanescent. This is the reason hunger passes away after a certain lapse of time, even if no food has been taken; it means simply that the contraction gave way to relaxation. A "good and hearty" appetite should not be encouraged, nor should it be regarded with complaisance. Such an appetite must be considered as pathologic and must invariably be suppressed by the physician, as it is caused by a stronger contraction, hence causing greater irritation of the mucosa, which should not be. Absence of contraction, the inability to contract, relaxation, distension—these being the opposite, the reverse of contraction, result in anorexia.

4. **Beriberi.**—McCool thoroughly reviews the literature and reports four cases which he believes are illustrative of four of the six forms of beriberi.

5. **Climate in Tuberculosis.**—Dunn states that since the dietetic-hygienic regimen may be much more thoroughly and efficiently conducted under certain climatic conditions, climate is a negligible factor only: (1) When the financial status of the patient is such that he cannot live in the health resort under conditions just as good as those obtainable at home, with or without the expenditure of the same amount of money; (2) when the patient has not the moral strength to make a business of getting well; (3) when the disease has become hopelessly advanced.

6. **Medical Treatment of Excessive Uric Acid in Urine.**—Robinson says that the rational treatment of excessive uric acid in the urine consists in the administration of ample fluids at regular intervals and of foods containing elements to produce basic combinations with the uric acid forming urates which are freely soluble. He advises the administration of a flavored 12-grain sodium chlorid tablet. The patient places on the tongue a half-tablet and drinks a glassful of water (better hot) before each meal, and in the middle of the forenoon (10 a. m.), middle of the afternoon (3 p. m.), and at bedtime (9 p. m.. The patient thus drinks three pints of 1/4 to 1/2 normal salt solution daily. This practically renders the urine normal, and acts as ample prophylaxis against the formation of uric acid calculus. If parenchymatous nephritis exists the salt should not be administered, as it excessively stimulates the renal parenchymatous cells. In such cases the water only should be given. An alkaline tablet is also given. It is composed of: Cascara sagrada, 1.6 mg. (1/40 gr.); aloes, .022 gm. (1/3 gr.); sodium bicarbonate, .065 gm. (1 gr.); potassium bicarbonate, .022 gm. (1/3 gr.); magnesium sulphate, .13 gm. (2 gr.). One-sixth to one tablet (or more as required to move the bowels once daily) is placed on the tongue before meals and followed by 236 c.c. (8 oz.) of water (better hot). At 10 a. m., 3 p. m. and bedtime one-sixth to one tablet is placed on the tongue and followed by a glassful of fluid. In the combined treatment the sodium chlorid tablet and alkaline tablet are both placed on the tongue together. This method furnishes alkaline bases (sodium and potassium) to combine with the free uric acid, in the urine, producing perfectly soluble alkaline urates and materially diminishing the free uric acid. The alkaline and sodium chlorid tablets take the place of all so-called mineral waters.

7 *Asthma. S. Kohn, New York.
8 Freedom from Uric Acid and How to Obtain It. A. Haig, London.
9 *Long Island Appendicitis. A. E. Gallant, New York.
10 *Lacerations of the Cervix Uteri. A. H. Gardner, New York.
11 Case of Delayed Menstruation; Flow Established at First Spontaneously. [illegible] atment; Conception. B. P. Hirst and [illegible]
12 *Serum Therapy in [illegible] er, New York.

7. **Asthma.**—Kohn discusses the clinical history of asthma exhaustively. He doubts the universal utility of operative work in the nose, but speaks highly of the value of institutional treatment for asthma and urges the establishment of sanatoria for this purpose.

9. **Long Island Appendicitis.**—Gallant discusses cases treated on Long Island and formulates the following rules for guidance in deciding when to operate: 1. With a history of sudden, sharp abdominal pain, soon followed by nausea and vomiting and fever, appendicitis may be surmised, and if a little later the pain becomes localized or most intense in the right iliac region, with right-sided rigidity, the diagnosis stands confirmed. 2. The "safe" treatment of acute or recurrent appendicitis during the attack is operation within the first forty-eight hours following the primary pain. 3. If toward the close of the second day, in spite of an icebag continuously applied over the appendicular region and free castor-oil evacuation of the bowels, the pain and rigidity, with or without nausea and vomiting, temperature and pulse elevation, continue or return, to delay operation under such conditions can only subject the patient to the danger of rupture, extensive gangrene, general peritonitis, intestinal obstruction, and a fatal issue. 4. In the presence of a mass or of tumefaction delay is dangerous—operate at once. 5. Interval operation is free from danger, requires but seven days in bed, two weeks from business, and gives freedom for life.

10. **Lacerations of Cervix Uteri.**—Gardner sums up his views

on this question as follows: 1. Many ills are the result of unrepaired lacerations of the cervix. 2. The frequency and extent of these tears may, to a certain extent, be lessened by allowing more time for dilatation in the first stage of labor; by a more judicious use of the forceps in time and force; and by the proper use of podalic version. 3. The most frequent cause of subinvolution of the uterus and prolonged convalescence is unrepaired lacerations. 4. In all probability many of the frequently quoted morbid conditions ascribed to lacerations are the result of infection of the lacerated surface rather than the laceration itself. 5. Many cases of severe hemorrhage are due to unrecognized cervical lacerations. 6. Immediate repair in the hands of an able surgeon-obstetrician is the best means of controlling such hemorrhage, and also of preventing infection of the torn surfaces. 7. Primary tracheoplasty is easily and quickly done, but a secondary repair is a difficult and tedious procedure. 8. In case of failure in obtaining union in the primary operation, the condition of the woman is none the worse, while if successful, which is usually the case with skillful surgeons, the patient is spared many of the ills which lacerations of the cervix sooner or later entail.

12. **Serum Therapy in Erysipelas.**—Ayer reports the results obtained in 33 additional cases. He says that the shortening of the average duration of the disease by 2.6 days expresses the value of this form of treatment.

14. **Astigmatism a Cause of Vomiting in School Children.**—Brav finds that some children, during their school term, have regular attacks of vomiting, the primary cause of which is often obscured. He says that it may be laid down as a rule that vomiting in school children, not preceded by a sensation of fullness, distress in epigastrium, epigastric pain, eructation of gases, regurgitation of fluid, heartburn, fever and chills, is caused by astigmatic errors of refraction which demand correction.

26 Dermoid Cysts of the Mediastinum. R. S. Morris, Ann Arbor, Mich. (Continued.)

21. **Appendicostomy and Cecostomy in Chronic Colitis.**—Since October, 1902, Meyer has made use of appendicostomy for obstinate chronic colitis, amebic as well as ulcerative, in four patients, and of cecostomy in one, a man in whom the appendix seemed of too small caliber to permit of thorough flushing. These five cases nicely demonstrate the great value of colon flushing in the various chronic affections of the large intestine, catarrhal, tuberculous, specific and amebic. Of course, in cases of chronic catarrh due to the presence of multiple papillomata, there is not much benefit to be derived from the treatment. They, further, show the excellence of Weir's idea of utilizing the appendix for this purpose, disproving the fear entertained by many, viz., that irrigation through a small tube would be unsatisfactory. If two quarts of fluid introduced through a tube 14 mm. in circumference, can be made to pass the entire large intestine within ten minutes, this is all that can be expected. Meyer says that in view of the obstinacy of ulcerative colitis in its various forms, and its tendency to recurrence, too much stress can not be laid on the advisability of keeping open the communication with the caput coli for a considerable length of time, and of insisting on a properly selected diet in conjunction with rational internal medication. Both must assist the salubrious effect of colon flushing. Meyer considers appendicostomy the operation of choice in all cases of obstinate, chronic colitis. It is simple, safe and effective, and the same is true of the after-treatment. He gives it the preference over cecostomy in all cases in which the appendix is passable.

29 Efficacy of Serum Treatment in Streptococcus Puerperal Septicemia. E. B. Young, Boston.
30 What the Suburban Surgeon is Doing in the Abdomen, and How He Does It. C. E. Durant, Haverhill, Mass.

27. **Empyema of Frontal Sinus.**—Caleb discusses the clinical history of this affection, and the methods of operating for its cure. He sums up the advantages and disadvantages of these methods as follows: The Ogsten-Luc operation has for advantage the slight deformity produced. For disadvantage it has the great probability of recurrence. The same is true of Jansen's method. Kuhnt's, Ridell's and Coakley's methods yield less probability of recurrence, as they destroy the sinus, but they produce greater or less facial deformity, Coakley's probably giving the least of the three. To all of these methods there is one great objection—that the ethmoid cells are not sufficiently considered. Killian's operation seems to combine the advantage of sinus obliteration with the removal of the ethmoid cells; but it is hard to judge as yet of its practical results as far as deformity and danger to the eye are concerned.

28. **Localization of Chronic Suppurations of Urinary Tract.**—Chute emphasizes careful location of chronic urinary suppurations as an essential for accurate treatment. He has found the conclusions drawn from the glass tests, as applied to suppurations of the urethra, often misleading, while those drawn from the irrigation test are more accurate. Without cystoscopic examination, it is at times almost impossible to differentiate chronic suppurations of the bladder from those of the kidney. Before operating on a suppurative lesion of the kidney it is essential to verify the diagnosis as to which kidney is involved, either by seeing turbid urine issuing from the corresponding ureteric orifice or by ureteral catheterization. Reliance on symptoms alone, even when these seem to leave no doubt, may lead to serious error.

42 *Celluloid Corset—Consideration of Its Usefulness and the Technic of Manufacture. H. W. Jones, St. Louis.

36. **Determination of Secreting and Evacuating Functions of the Stomach.**—McGrew describes his method as follows: In the morning, fasting, the patient is given a test meal consisting of 60 grams of biscuit and 240 c.c. of a solution made up of 30 c.c. of the iron indicator and 210 c.c. distilled water. For practical purposes nine biscuits and an eight-ounce bottle filled to the neck, putting in first the 30 c.c. iron solution and adding distilled water, will afford a ready means of dosage and be surprisingly accurate. One hour after its ingestion the test meal is withdrawn, following the Mathieu-Rémond technic. To dilute the stomach contents, pour into the stomach, through the tube, 200 c.c. of distilled water. The patient then mixes the water and stomach contents thoroughly by active abdominal and diaphragmatic movements, which should be continued about two minutes, after which period the diluted specimen may be withdrawn, the tube having remained meanwhile *in situ*. In order to make the calculations it is necessary to know: 1, the quantity of the undiluted specimen; 2, the acidity of the undiluted specimen; 3, the acidity of the diluted specimen; 4, the quantity of iron which remained in the stomach into a graduate the first point is settled without more ado. Set the diluted specimen to filter. Thoroughly and vigorously stir the undiluted specimen with glass rod, after which 20 c.c. should be measured from it into an evaporating dish, and the remainder set to filter. To the 20 c.c. add 8 to 10 drops pure hydrochloric acid and 8 to 10 drops pure nitric acid, and boil the whole for several moments until the excess of nitric acid has been entirely driven off. Then add enough distilled water to bring the amount again to 20 c.c. and filter. To 10 c.c. of the filtrate add 5 c.c. of a 5 per cent. solution of ammonium sulphocyanid. Compare the color of this mixture with that of a standard solution composed of a 1/10 dilution of the mother iron solution, 10 c.c. of which (after the iron has been reduced to the chlorid by adding three or four drops of pure HCl and boiling until clear) are treated with 5 c.c. of the same 5 per cent. ammonium sulphocyanid solution. This is the ordinary colorimetric process. For example: Comparing the filtrate mixture and the standard solution, it appears that the former is a lighter shade, hence contains less iron. Add, therefore, mother solution of iron (reduced as above), drop by drop, reversing the tube back and forth after each to thoroughly mix the solutions, until the colors in the two tubes exactly correspond. Then, taking the lower level of the discus, calculate the amount of iron added. Suppose the tube to have contained 10 c.c. filtrate to which 5 c.c. ammonium sulphocyanid solution has been added, and the tube shows that 6 c.c. mother iron solution has been added to bring the color up to the standard. The 6 c.c. mother iron solution contains 6 mg. iron, but the same quantity of the standard solution contains 1 mg. iron. Therefore, the 10 c.c. filtrate contains 4 mg. iron. It remains to determine the total stomach contents, when the quantity of test meal remnant may be easily calculated. Using phenolphthalein as an indicator, ascertain the acidity of the diluted and the undiluted specimens respectively. Then calculate the total stomach contents by multiplying the acidity of the diluted specimen (A') by the quantity of water introduced (Q), and dividing the result by the acidity of the undiluted (A) minus that of the diluted specimen (A'). Suppose the total stomach contents are found to have been 160 c.c. It has been previously determined that each 10 c.c. contain .4 mg. iron; but each 1 mg. is equivalent to 10 c.c. of the original test meal. Therefore, 64 c.c. of the original test meal remained within the stomach and 236 c.c., or 78 per cent., had been evacuated. The evacuatory percentage is, therefore, 78. The volume of the gastric juice is the total stomach contents, 160 c.c., less the volume of the test meal remnant, 64 c.c., or 96 c.c. This is 1.5 times the volume of the test meal remnant. The secretory percentage, therefore, is 150.

39. **Diagnosis of Ureteral Stones.**—According to Harris, a diagnosis of ureteral stones based on the symptomatology can never be more than presumptive, and previous to the advent of the Roentgen ray and the ureteral catheter, a diagnosis of ureteral stone in any portion of the ureter, except the lower end, was seldom made, except at operation. There may be other bodies in the pelvis capable of casting shadows which from appearances alone can not be distinguished from shadows cast by ureteral stones. Hence, in some of these cases a correct diagnosis can be made only by the use of the ureteral bougie.

41. **New Clinical Phenomena.**—Chromo-diagnosis is a word coined by Abrams to describe a method of examination which is specially applicable in the early detection of distended cutaneous veins. One may use colored glass, or, better still, sheets of gelatin of various colors, purchasable from any dealer in magic lanterns. For convenience the sheets may be mounted in cardboard frames. The patient faces the light, while the observer faces the patient. It will be found by looking through either magenta or red-colored gelatin, that the veins are brought into special prominence, and that many veins not evident to the unaided eye can be detected by the colors mentioned. Yellow gelatin will aid in the detection of the diaphragmatic excursions, although to a degree less evident than by painting the skin over the cutaneous arc described by the excursions of the diaphragm with an alcoholic solution of gamboge. Green causes red cutaneous areas to appear black like silhouettes, whereas yellow intensifies the color of erythematous patches. Violet intensifies the most insignificant erythematous area. Blue intensifies brown spots. Violet causes yellow skin lesions to assume a salmon-pink color. The use of the foregoing colors refers to the effects obtained in daylight. Icteric coloration is not demonstrable by gaslight, but when a violet gelatin sheet is employed yellow is seen as a dark yellow. Let the patient rest in the recumbent posture with head nearest to the window, so that the light falls on the exposed chest from behind. The observer stands at the side of the patient, holding in his hand a red gelatin sheet in such a way that the light filtering through the sheet falls on the chest. In a thin subject, especially during forced inspiration, and with the sheet properly adjusted, the chest presents a skeletal appearance and the intercostal spaces are clearly differentiated from the ribs. In the examination of several cases of pneumothorax and hydrothorax the foregoing differentiation was found to be less pronounced or absent, and for this reason chromo-diagnosis may serve as an aid in the diagnosis of the affections mentioned.

42. **Celluloid Corset.**—The method of making the corset employed by Jones consists in pouring a plaster form of the body or part in question, smoothing and finishing this form or model, applying undershirts one after another on this form, and painting each one of these with the celluloid solution, until the desired thickness has been reached. A plaster cast of the trunk is first taken. This is filled with liquid plaster made just thick enough to pour with some difficulty. The cast is usually set first on a box, over a hole, which has been cut through the top, just large enough to admit a heavy stick, which is used to support the form. The object in having the central support larger at one end than at the other is twofold—to save as much plaster as possible in pouring, and to allow the support to be slightly withdrawn an hour or so after the plaster becomes hard. This can be done by resting the plaster form on some object and tapping the end of the support with a hammer until it is driven out a few inches. This will be more easily accomplished if the bar be greased previous to pouring. If this procedure be not gone through with, the water which remains in the plaster form will be absorbed by the wood, and in a few hours the swelling which takes place will break the form. If a bar of iron or piping be used in place of wood there is no danger of the form cracking, but in such case the bar must remain in the plaster and can not be used again without destroying the form. After the form has been poured twenty-four hours the cast can be stripped off, and this will be more easily accomplished if the inner side has been previously coated with vaselin. The form

should then be smoothed down carefully with a draw shave to cut down all humps, and later with a paper cutter's knife. All hollows should be filled with liquid plaster until the whole is fairly smooth. In making leather jackets it is usual to cover the form with a coating of shellac. This should never be done in making the celluloid jacket, as the acetone used later will cause the jacket to adhere to the cast so strongly that it will be ruined in removing. Instead, after the form is perfectly smooth, it should be rubbed down with talcum powder until the surface is shiny. The form is then ready for applying the celluloid. A supply of women's summer undershirts should be obtained or, if the jacket be a small one, children's undershirts. From five to eight or nine shirts will be used, according to the thickness of the jacket. Two of these are now fitted on the form, one over the other, and made to lie perfectly smooth. The celluloid, which will be the color of honey and the consistency of molasses, is poured from the bottle, preferably into a tall graduate of a pint capacity, and larger at the top than at the bottom. A bowl can be used, or, in fact, any receptacle, but the graduate is convenient to mix the celluloid with more acetone, when it is too thick, and in other ways has proved the best. An ordinary painter's brush, three inches wide, is used for applying the liquid celluloid, which is laid on the shirted form and spread over evenly and rubbed in. It is not necessary to wait until one coat is dry before adding the next, as the acetone evaporates almost immediately. Three or four coats are painted on, and when the meshes of the shirt seem well filled and the celluloid begins to run over and around the sides of the form (the number of coats will depend on the consistency of the celluloid), no more should be applied for ten minutes. Then, while the celluloid in the shirts is still rather soft, another shirt is put on. This will adhere immediately and should be made perfectly smooth. This is filled in the same way, and the process is repeated until the desired number of shirts is used. If time is no object, the shirts may be allowed to dry one by one, and the process extended over several days. In order to ascertain when the desired thickness has been reached it is necessary to trim the jacket at the edge of the form, where the redundant undershirt overhangs, but care must be taken that a good clean cut be made downward and at a distance of a fraction of an inch inside the edge, as at the edge and beyond, the cut jacket will appear much thicker than it really is, since the different layers at this point are not so firmly matted together. The average thickness is from 2 to 3 mm., and it is rare that less than seven shirts are used. When the desired thickness has been reached, several layers are applied to the last shirt, until no more can be taken up. When dry the jacket will be smooth and shiny and of a yellow color. It can be made white by the addition of zinc oxid to the last few layers of celluloid, although this makes it duller. If too much zinc oxid is used, in case a very white jacket is desired and the last two or three shirts have been painted with the white solution, the jacket will be somewhat weakened, since the zinc makes the celluloid brittle. This is true also when white celluloid is used originally instead of the yellow. After the jacket is finished it should be allowed to remain on the plaster form for about a week. In the meantime it may be trimmed around the edges with a sharp, strong knife. In a week it will be dry enough to remove. A clean cut should be made directly down the middle into the plaster, the edges pried up and the jacket stripped off. If talcum powder has been used the jacket slips off easily, especially if the form has been well smoothed, but occasionally a little plaster will adhere to the inner side. This can be scraped out with a knife. The inside is never coated with celluloid, as it invariably changes the shape of the jacket. The jacket can now be tried on and trimmed out under the arms and at the bottom, so as to allow for sitting down, but it should not be allowed to remain very long off the form, as it has a tendency to curl up at the edges. When properly fitted, have a harness-maker bind the edges with leather, paste pads of felt where the jacket will come in contact with bony prominences, and either sew straps and buckles in front or insert hooks for lacing. Five or six straps are usually sufficient. When extra support is needed use strips of steel riveted to the jacket or attach apparatus to the jacket. Thus the actual outlay for materials in no case will exceed $14 or $15, and in most cases will be less than $10.

43 *Radical Operation for the Cure of Chronic Frontal Sinusitis. T. J. Harris, New York.
44 *Brief Analysis of 350 Cases of Epilepsy. H. M. Cox, New York.
45 Stricture of the Eustachian Tube. W. C. Phillips, New York.

43. **Radical Operation in Chronic Frontal Sinusitis.**—The various operations employed in the treatment of this affection are discussed by Harris. He prefers Killian's operation which, he says, is indicated in many cases and gives uniformly good results.

44. **Epilepsy.**—Nearly all the patients constituting the series of 350 cases analyzed by Cox were chronic epileptics, representing almost all types of the disease. About 41 per cent. (146) were women, and 58 per cent (204 cases) were men. Fifty-six per cent. (196) occurred in the first decade of life; 27 per cent. (95) in the second; 11 per cent. (39) in the third; 4 per cent. (14) in the fourth, and 1.4 per cent. (5) in the fifth, and only one case occurred after the fifth decade. In 15 cases one or both parents were epileptic; in eight the father alone was affected. In 20 cases there was a history of epilepsy in the grandparents, uncles and aunts. In 18 cases in which epilepsy was not traceable in the ancestors, brothers and sisters were affected. Indirect hereditary influences were present as follows: Tuberculosis in 24 cases; alcoholism in 17 cases; neurasthenia and hysteria in 9 (in four instances it was in the mother); cancer in 6 cases; insanity, 5 cases; apoplexy, organic heart disease and paralysis, 12 cases; migraine, 3; paresis and nephritis, each 2; tabes, meningitis and diabetes, each 1. The exciting cause attributed in 157 of the cases under consideration was as follows: Dentition, 22; menstrual disorders, 21; trauma, 17, in at least 6 of which the attack caused the fall resulting in injury rather than the injury causing the attack; alcoholism, 10; masturbation, 9; cerebral palsies, 8; meningitis, 8; encephalitis, 7; scarlatina, 6; grief and anxiety, 5; measles, 5; diphtheria, 4; chorea, 4; hydrocephalus, 4; idiocy, 15; malaria, menopause, smoking, syphilis and autointoxication, each 2, and eyestrain, parotitis, dysentery and erysipelas, each 1. As to treatment, Cox says when the lesions can be localized and the vitality of the patient is sufficiently high, surgery should be resorted to, other measures failing, although the results obtained from operative interference are seldom curative, and, unfortunately, are disappointing.

36. **Determination of Secreting and Evacuating Functions of the Stomach.**—McGrew describes his method as follows: In the morning, fasting, the patient is given a test meal consisting of 60 grams of biscuit and 240 c.c. of a solution made up of 30 c.c. of the iron indicator and 210 c.c. distilled water. For practical purposes nine biscuits and an eight-ounce bottle filled to the neck, putting in first the 30 c.c. iron solution and adding distilled water, will afford a ready means of dosage and be surprisingly accurate. One hour after its ingestion the test meal is withdrawn, following the Mathieu-Rémond technic. To dilute the stomach contents, pour into the stomach, through the tube, 200 c.c. of distilled water. The patient then mixes the water and stomach contents thoroughly by active abdominal and diaphragmatic movements, which should be continued about two minutes, after which period the diluted specimen may be withdrawn, the tube having remained meanwhile *in situ*. In order to make the calculations it is necessary to know: 1, the quantity of the undiluted specimen; 2, the acidity of the undiluted specimen; 3, the acidity of the diluted specimen; 4, the quantity of iron which remained in the stomach into a graduate the first point is settled without more ado. Set the diluted specimen to filter. Thoroughly and vigorously stir the undiluted specimen with glass rod, after which 20 c.c. should be measured from it into an evaporating dish, and the remainder set to filter. To the 20 c.c. add 8 to 10 drops pure hydrochloric acid and 8 to 10 drops pure nitric acid, and boil the whole for several moments until the excess of nitric acid has been entirely driven off. Then add enough distilled water to bring the amount again to 20 c.c. and filter. To 10 c.c. of the filtrate add 5 c.c. of a 5 per cent. solution of ammonium sulphocyanid. Compare the color of this mixture with that of a standard solution composed of a 1/10 dilution of the mother iron solution, 10 c.c. of which (after the iron has been reduced to the chlorid by adding three or four drops of pure HCl and boiling until clear) are treated with 5 c.c. of the same 5 per cent. ammonium sulphocyanid solution. This is the ordinary colorimetric process. For example: Comparing the filtrate mixture and the standard solution, it appears that the former is a lighter shade, hence contains less iron. Add, therefore, mother solution of iron (reduced as above), drop by drop, reversing the tube back and forth after each to thoroughly mix the solutions, until the colors in the two tubes exactly correspond. Then, taking the lower level of the discus, calculate the amount of iron added. Suppose the tube to have contained 10 c.c. filtrate to which 5 c.c. ammonium sulphocyanid solution has been added, and the tube shows that 6 c.c. mother iron solution has been added to bring the color up to the standard. The 6 c.c. mother iron solution contains 6 mg. iron, but the same quantity of the standard solution contains 1 mg. iron. Therefore, the 10 c.c. filtrate contains 4 mg. iron. It remains to determine the total stomach contents, when the quantity of test meal remnant may be easily calculated. Using phenolphthalein as an indicator, ascertain the acidity of the diluted and the undiluted specimens respectively. Then calculate the total stomach contents by multiplying the acidity of the diluted specimen (A') by the quantity of water introduced (Q), and dividing the result by the acidity of the undiluted (A) minus that of the diluted specimen (A'). Suppose the total stomach contents are found to have been 160 c.c. It has been previously determined that each 10 c.c. contain .4 mg. iron; but each 1 mg. is equivalent to 10 c.c. of the original test meal. Therefore, 64 c.c. of the original test meal remained within the stomach and 236 c.c., or 78 per cent., had been evacuated. The evacuatory percentage is, therefore, 78. The volume of the gastric juice is the total stomach contents, 160 c.c., less the volume of the test meal remnant, 64 c.c., or [illegible] c.c. This is 1.5 times the volume of the test meal remnant. The secretory percentage, therefore, is 150.

39. **Diagnosis of Ureteral Stones.**—According to Harris, a diagnosis of ureteral stones based on the symptomatology can never be more than presumptive, and previous to the advent of the Roentgen ray and the ureteral catheter, a diagnosis of ureteral stone in any portion of the ureter, except the lower end, was seldom made, except at operation. There may be other bodies in the pelvis capable of casting shadows which from appearances alone can not be distinguished from shadows cast by ureteral stones. Hence, in some of these cases a correct diagnosis can be made only by the use of the ureteral bougie.

41. **New Clinical Phenomena.**—Chromo-diagnosis is a word coined by Abrams to describe a method of examination which is specially applicable in the early detection of distended cutaneous veins. One may use colored glass, or, better still, sheets of gelatin of various colors, purchasable from any dealer in magic lanterns. For convenience the sheets may be mounted in cardboard frames. The patient faces the light, while the observer faces the patient. It will be found by looking through either magenta or red-colored gelatin, that the veins are brought into special prominence, and that many veins not evident to the unaided eye can be detected by the colors mentioned. Yellow gelatin will aid in the detection of the diaphragmatic excursions, although to a degree less evident than by painting the skin over the cutaneous arc described by the excursions of the diaphragm with an alcoholic solution of gamboge. Green causes red cutaneous areas to appear black like silhouettes, whereas yellow intensifies the color of erythematous patches. Violet intensifies the most insignificant erythematous area. Blue intensifies brown spots. Violet causes yellow skin lesions to assume a salmon-pink color. The use of the foregoing colors refers to the effects obtained in daylight. Icteric coloration is not demonstrable by gaslight, but when a violet gelatin sheet is employed yellow is seen as a dark yellow. Let the patient rest in the recumbent posture with head nearest to the window, so that the light falls on the exposed chest from behind. The observer stands at the side of the patient, holding in his hand a red gelatin sheet in such a way that the light filtering through the sheet falls on the chest. In a thin subject, especially during forced inspiration, and with the sheet properly adjusted, the chest presents a skeletal appearance and the intercostal spaces are clearly differentiated from the ribs. In the examination of several cases of pneumothorax and hydrothorax the foregoing differentiation was found to be less pronounced or absent, and for this reason chromo-diagnosis may serve as an aid in the diagnosis of the affections mentioned.

42. **Celluloid Corset.**—The method of making the corset employed by Jones consists in pouring a plaster form of the body or part in question, smoothing and finishing this form or model, applying undershirts one after another on this form, and painting each one of these with the celluloid solution, until the desired thickness has been reached. A plaster cast of the trunk is first taken. This is filled with liquid plaster made just thick enough to pour with some difficulty. The cast is usually set first on a box, over a hole, which has been cut through the top, just large enough to admit a heavy stick, which is used to support the form. The object in having the central support larger at one end than at the other is twofold—to save as much plaster as possible in pouring, and to allow the support to be slightly withdrawn an hour or so after the plaster becomes hard. This can be done by resting the plaster form on some object and tapping the end of the support with a hammer until it is driven out a few inches. This will be more easily accomplished if the bar be greased previous to pouring. If this procedure be not gone through with, the water which remains in the plaster form will be absorbed by the wood, and in a few hours the swelling which takes place will break the form. If a bar of iron or piping be used in place of wood there is no danger of the form cracking, but in such case the bar must remain in the plaster and can not be used again without destroying the form. After the form has been poured twenty-four hours the cast can be stripped off, and this will be more easily accomplished if the inner side has been previously coated with vaselin. The form

should then be smoothed down carefully with a draw shave to cut down all humps, and later with a paper cutter's knife. All hollows should be filled with liquid plaster until the whole is fairly smooth. In making leather jackets it is usual to cover the form with a coating of shellac. This should never be done in making the celluloid jacket, as the acetone used later will cause the jacket to adhere to the cast so strongly that it will be ruined in removing. Instead, after the form is perfectly smooth, it should be rubbed down with talcum powder until the surface is shiny. The form is then ready for applying the celluloid. A supply of women's summer undershirts should be obtained or, if the jacket be a small one, children's undershirts. From five to eight or nine shirts will be used, according to the thickness of the jacket. Two of these are now fitted on the form, one over the other, and made to lie perfectly smooth. The celluloid, which will be the color of honey and the consistency of molasses, is poured from the bottle, preferably into a tall graduate of a pint capacity, and larger at the top than at the bottom. A bowl can be used, or, in fact, any receptacle, but the graduate is convenient to mix the celluloid with more acetone, when it is too thick, and in other ways has proved the best. An ordinary painter's brush, three inches wide, is used for applying the liquid celluloid, which is laid on the shirted form and spread over evenly and rubbed in. It is not necessary to wait until one coat is dry before adding the next, as the acetone evaporates almost immediately. Three or four coats are painted on, and when the meshes of the shirt seem well filled and the celluloid begins to run over and around the sides of the form (the number of coats will depend on the consistency of the celluloid), no more should be applied for ten minutes. Then, while the celluloid in the shirts is still rather soft, another shirt is put on. This will adhere immediately and should be made perfectly smooth. This is filled in the same way, and the process is repeated until the desired number of shirts is used. If time is no object, the shirts may be allowed to dry one by one, and the process extended over several days. In order to ascertain when the desired thickness has been reached it is necessary to trim the jacket at the edge of the form, where the redundant undershirt overhangs, but care must be taken that a good clean cut be made downward and at a distance of a fraction of an inch inside the edge, as at the edge and beyond, the cut jacket will appear much thicker than it really is, since the different layers at this point are not so firmly matted together. The average thickness is from 2 to 3 mm., and it is rare that less than seven shirts are used. When the desired thickness has been reached, several layers are applied to the last shirt, until no more can be taken up. When dry the jacket will be smooth and shiny and of a yellow color. It can be made white by the addition of zinc oxid to the last few layers of celluloid, although this makes it duller. If too much zinc oxid is used, in case a very white jacket is desired and the last two or three shirts have been painted with the white solution, the jacket will be somewhat weakened, since the zinc makes the celluloid brittle. This is true also when white celluloid is used originally instead of the yellow. After the jacket is finished it should be allowed to remain on the plaster form for about a week. In the meantime it may be trimmed around the edges with a sharp, strong knife. In a week it will be dry enough to remove. A clean cut should be made directly down the middle into the plaster, the edges pried up and the jacket stripped off. If talcum powder has been used the jacket slips off easily, especially if the form has been well smoothed, but occasionally a little plaster will adhere to the inner side. This can be scraped out with a knife. The inside is never coated with celluloid, as it invariably changes the shape of the jacket. The jacket can now be tried on and trimmed out under the arms and at the bottom, so as to allow for sitting down, but it should not be allowed to remain very long off the form, as it has a tendency to curl up at the edges. When properly fitted, have a harness-maker bind the edges with leather, paste pads of felt where the jacket will come in contact with bony prominences, and either sew straps and buckles in front or insert hooks for lacing. Five or six straps are usually sufficient. When extra support is needed use strips of steel riveted to the jacket or attach apparatus to the jacket. Thus the actual outlay for materials in no case will exceed $14 or $15, and in most cases will be less than $10.

52. **Rational Therapy.**—Bell calls attention to the fact that while preventive medicine is steadily moving onward, winning victories on every hand, therapeutics has for years occupied, and still occupies, an unenviable position, and that this is especially true of drug treatment. He states that therapy is the one weak link in medicine. He reviews the treatment of disease during the last three decades and discusses the relation of physicians to proprietary medicines. The following reasons, he thinks, are responsible for the present state of affairs: 1. Insufficient and impractical instruction in this branch of medicine. 2. The unfortunate tendency in medical schools to devote all energy to the investigation, detection and prevention of disease, to the exclusion of rational therapy. 3. The delusion of considering drugs the only agents for combating disease, thus seriously minimizing the beneficial effects of modern therapy. 4. The willingness of a considerable part of the profession to prescribe anything and everything thrust on the market, regardless of composition or merit. 5. The worse than evil influence of the so-called therapeutic nihilists in the ranks of the profession. Bell reviews the various means of remedying this state of affairs and refers to the work of the Council on Pharmacy and Chemistry in the following terms:

> The important work undertaken by the Council on Pharmacy and Chemistry of the American Medical Association, will doubtless prove exceedingly helpful and beneficial to the entire profession, [illegible] the indifferent prescriber, ready and willi[illegible] and everything, regardless of merit. The [illegible] l Chemistry, composed of able and experienced pharmacists and chemists, proposes to examine into the composition and the status of the various medical preparations offered to physicians, which are not included in the United States Pharmacopeia or in other standard text-books. These will include the synthetic chemical compounds, as well as the so-called proprietaries and pharmaceutical specialties put out under trademarked names. Preparations which conform to the standard established by the Council will be incorporated in "New and Nonofficial Remedies," a book to be published by THE JOURNAL of the American Medical Association. This distinguished body of impartial experts should receive the hearty co-operation of all honorable manufacturing pharmacists and chemists, and of the entire medical profession, in making this important work in the highest degree successful. Let us hope that this important work will be fearlessly pursued, in order that reliable results may follow.

He says that with the new and expurgated pharmocopeia and the valuable aid of the Council on Pharmacy and Chemistry, with the growing feeling in the profession in favor of a rational therapy, we may hope to see the weak link in medicine, therapeutics, so strengthened in the near future as to commend itself alike to the public and to the skeptic within the profession. He also refers at some length to the need of medical education and of uniform medical laws.

53. **Renal Decapsulation.**—After careful study of the literature and observations in a personal case, Schmauss concludes that the Edebohls operation is deserving of further trial, and that we are not only justified in recommending it in suitable cases, after the various therapeutic measures have been sufficiently tried and found wanting, but that it is our duty to do so. This operation, like any other, has not only its indications, limitations and contraindications, as already pointed out, but also its difficulties—(a) unusually small space between last rib and ilium, either due to a short waist, or great length and obliquity of the twelfth rib; (b) undue mobility of the kidney, so that it may be difficult to locate it; (c) perinephritic adhesions or high locations up under the ribs—especially when enlarged, as in his case; (d) firm attachment of the capsule proper in some cases of interstitial nephritis. Certain precautions must be observed to insure the best results: 1, The patient should be carefully prepared for the operation; 2, the development of shock and anuria should be counteracted by appropriate measures; 3, the ilio-hypogastric and ilio-inguinal nerves are to be preserved; 4, undue trauma to the kidney proper and the surrounding structures should be avoided; 5, in replacing the kidney care must be exercised to avoid twisting the pedicle. Much has been said about posturing the patient to facilitate delivery of the kidney; this will increase the working space and help to bring up a loose kidney, but will not influence a normally situated kidney up under the ribs. On the contrary, it has occurred to Schmauss that a pillow or roll might increase the difficulty. Grasping the fatty capsule with a number of small forceps, and thus drawing out the organ, has been advised, but this is only possible if the kidney is movable. Schmauss makes an oblique incision parallel with the twelfth rib, and, if necessary, resecting the latter. Thus retraction can be exerted upward and thereby the kidney rendered more accessible and more room obtained for the hand. In this way considerable time is saved, the fat is disturbed less, and the kidney is spared undue trauma—through handling, pulling, tearing, etc.

55. **Determination of Errors of Refraction.**—Spratt recorded the comparative results obtained with the use of charts without cycloplegia and again of the same eye after instillation of homatropin, 2 per cent., every ten minutes, for a period of one and one-half hours. The patients, all of whom were adults except six, were selected only with reference to their intelligence. In 95 per cent. of cases the astigmatism determined by the use of charts and fogging, but without cycloplegia, was within .25 D. of that found after the use of homatropin. This includes 95 (75 per cent.), of a total of 126 eyes in which there was no difference in the amount. In 4 cases there was an apparent error of .37 D. and in one case an error of .50 D. No eye in the above series would have been given too strong a concave glass if the cycloplegic had been omitted. In two-thirds of the eyes the total myopia corresponded exactly with that found under a cycloplegic. The remaining one-third would have been under-corrected from .12 D. to .37 D. Several cases showing from —.3 D. to —.7 D. of myopia are included in the above. As would be expected, there was less uniformity in results obtained in the eyes showing hypermetropia. Fourteen cases showed less than .50 D. and in 35 eyes (or 42 per cent.), the total hypermetropia was correctly determined without cycloplegia. Spratt concludes his paper as follows: With intelligent adults, subjective methods of refracting are preferable to objective methods. The comparison of two lines at right angles, these corresponding to the axis of maximum and minimum refraction of the dioptric system of the eye, is a more accurate method of determining errors of refraction than by the use of test letters. Astigmatic charts, as devised by Verhoeff, are preferable to the single line charts, as the contrast produced by the cross lines enables one to estimate more accurately any difference in distinctiveness in the test lines corresponding to meridians of maximum and minimum refraction. In practically all cases the astigmatism and myopia can be as accurately determined without as with cycloplegia. A large proportion of cases of hypermetropia can be satisfactorily refracted without the use of cycloplegia.

13. **Frontal Sinusitis.**—Thomson reports 2 cases, both terminating fatally. In the first case the cause was meningitis following an osteomyelitis due to septic absorption from chronic suppuration in the frontal and ethmoidal sinuses. Evidently the traumatism caused by the Caldwell-Luc operation performed on the left maxillary sinus stimulated the latent suppuration in the ethmoid and frontal cavities of the same side, and surgical treatment of the left frontal sinus led to septic absorption from the chronic suppuration going on in the frontal and ethmoidal sinuses on the opposite side. This patient died three months from the onset of symptoms and two months from the first opening of the left frontal sinus. The second patient died about a year and a half after the first operation from a meningitis caused by subdural abscesses. Thomson concludes as follows: 1. In cases of multisinusitis it is well to drain the maxillary cavity some time before the frontal sinus is operated on. Both cavities may be operated on at the same time; but if only one sinus is operated on at a time it should be the frontal sinus, the lower cavity being drained until it can be opened. 2. In spite of a free opening of the frontal sinus, the establishment of a large communication with the nose, and the avoidance of closure of the external wound, a slow infection of the bone may take place leading ultimately to infection of the meninges. This may even be started in suppurating cavities on the side opposite to the one operated on. 3. The local condition of the wound, as well as the pulse, temperature and feelings of the patient, may fail to indicate the onset of mischief. After from one to three weeks this is revealed by headache, pain, tenderness and puffy swelling on the forehead or around the eyes. 4. When septic osteomyelitis has started the most vigorous measures may fail to arrest it. It may last one and a half years before terminating fatally. 5. The chief danger appears to lie in the ethmoidal labyrinth, owing to its anatomic irregularities and to the difficulty of treating them satisfactorily. 6. Up to the present the operation which best meets these difficulties is that of Killian. In many cases a preliminary endonasal operation on the ethmoid is advantageous.

15. **Aspiration in Diseases of the Ear and Nose.**—Sondermann has devised an apparatus for aspiration in diseases of the ear and of the nose which, he believes, possesses no disadvantages. It consists of a hollow mask open at one side and surrounded by a hollow ring of hardened rubber, and by means of an elastic tube it is connected with the suction ball. The latter, as well as the elastic tube, possesses a valve by which the air can only pass outward after the suction ball has been compressed. As the mask is of triangular shape it can also be applied to the nose if required. By a slight pressure it fits almost hermetically on the skin and, therefore, can be applied easily at any time by the patient himself without the help of another person. There is no contact whatever with the external meatus and its contents and there is scarcely any danger to be feared from too strong a suction, as the rarefaction of air is spread over a relatively large space and can not exceed the amount corresponding to the elasticity of the suction ball. In cases of acute suppuration a slight aspiration will be found sufficient in order to evacuate the pus from the middle ear and even from the cells of the mastoid process into the external meatus. On the other hand, in cases of chronic empyema a stronger suction ball can be used, and especially when the membrana tympani or the ossicles are partly or entirely missing. Then it will be possible to exert a more intense suction, by which less fluid secretions are discharged if the nidus is connected with the middle ear. To this must be added that the walls of the cavity are artificially rendered hyperemic. In two cases of acute suppuration of the middle ear in which the mastoid process was also affected by the disease, as was shown by the swelling and the tenderness, and in which the intense pain continued in spite of the free and copious discharge of pus, the aspect of both the cases changed at once after the pus had been evacuated several times a day by aspiration. The pain and tenderness ceased almost directly as well as the discharge and the patients rather liked the aspiration because they felt an immediate relief in both head and ear. The result of the treatment has also been satisfactory, for the condition of the ears after the application was by no means worse than it had been before. It appears from this that the ears had not in any way been injured by the suction method, although it had been frequently applied. On the other hand, it is scarcely to be feared that any harm should result as the suction force required for evacuating pus is but slight. There is no doubt but that the patients are treated in this way far more pleasantly than by attempts at removing pus by compressing the air in the Eustachian tube or in the external meatus. The apparatus used for the suction method when applied to the nose has the same form as the one described above, but, of course, its mask is smaller, as the two nostrils and their immediate neighborhood only need be hermetically closed.

17. **Congenital Multiple Occlusions of Small Intestine.**—The small intestine of the patient, in the case reported by Emanuel, was occluded in three places, while in five others the lumen of the bowel was practically obliterated by angular constructions giving rise to a localized distention of the intestine immediately above, and a relative collapse below the points of construction. The specimen was taken from an infant seven months old. Operative interference was deemed inadvisable. On opening the abdomen at autopsy, the most conspicuous feature was a distended duodenum which was of even greater volume than the stomach. The bowel was completely obliterated at the duodeno-jejunal junction. The second and third obliterations were found in the jejunum. The annular constrictions were all situated in the jejunum.

18. **Silver Wire and Electricity in Aneurism of Abdominal Aorta.**—The aorta having been exposed, Griffiths selected a spot on the surface of the tumor devoid of large vessels, and enclosed a small circle in a purse-string suture. Through the center of this a fine long metal trocar and cannula were thrust well into the sac. The trocar was withdrawn, the cannula remaining in position, and through this was introduced a vulcanite cannula for insulating purposes. Next some fine silver wire was introduced into the sac through the double cannula. After a foot or so of wire was introduced the wire kinked, so it was cut off flush with the cannula and pushed home with a ramrod which had been specially prepared with a cupped end for this purpose. Some more wire was then pushed through and connected with the negative terminal of a constant current battery, the circuit being completed through the patient by means of an electrode placed on the thorax. A current of from 15 to 25 milliamperes was given and continued for 15 minutes. At the end of this time it was noticed that the aneurism felt harder and the expansile pulsation had grown less even if it had not quite disappeared. The wire (about six feet) was then pushed home with the ramrod, and the cannula withdrawn. The purse-string suture was tied, and the abdomen closed. It was noticed after the abdomen was closed that the bulging caused by the tumor had almost disappeared. The patient suffered greatly from shock and although consciousness was recovered, restlessness was very marked, the patient throwing himself about and exhausting what little pulse remained. He died five and a half hours after operation. The postmortem examination showed that there had been no hemorrhage. The heart was healthy; the arch of the aorta showed signs of atheromatous changes. The aneurism came off from the main trunk of the abdominal aorta and communicated with it by means of a narrow elongated mouth about one and a half inches in length. The sac was filled with a dark clot and coiled wire, a double loop of which had entered the aorta and passed for about two and a half inches up into the thoracic aorta. There was no erosion of the vertebræ.

22. Luxation of Atlas in Man of Megalithic Age.—Baudouin, in conducting antiquarian researches in the western part of France last year, excavated a skeleton with forward dislocation of the atlas. The skeleton was found under an enormous slab of stone, and before it was removed it was preserved intact by pouring a solution of silica over it. The depression in which it lay was also silicated, thus confirming the findings in the skeleton. The luxation was evidently accidental, due to the falling of the large slab. Baudouin reviews other cases of forward luxation of the atlas on record, showing the exact correspondence with the findings in this skeleton of a prehistoric being.

24. Hydatid Embolism of Pulmonary Artery.—The syndrome induced may be that of ordinary embolism of the lungs, or it may be modified by the character of the embolus. The special syndrome is characterized by sudden onset accompanied by symptoms suggesting ordinary pulmonary embolism, but with the intense, persisting dyspnea unaccompanied by distinct stethoscopic signs. Hemoptysis and symptoms of asystole also develop, terminating fatally in time. In some cases an ascending infection hastens the accidents and death ensues in a syndrome suggesting pneumonia. A history of hydatid cysts elsewhere facilitates the diagnosis. The hydatid vesicle does not completely obstruct the vessel, nor does it entail secondary thrombosis, but the disturbance in the circulation proves fatal sooner or later. In the 12 cases on record, the affection had a protracted course in 4. The patient in the case described was a printer of 42, previously apparently healthy, who succumbed in a few days with dyspnea, cyanosis and other symptoms suggesting pneumonia.

25. Hydro-Hemolysis Test for Tubercle Bacilli.—Ten c.c. of human blood are diluted with 200 gm. of distilled water which destroys the blood corpuscles almost at once. The limpid fluid is then distributed in two or three vials and centrifuged; the sediment is then spread on six or eight cover glasses and examined for bacilli. These stain and show up finely, and are detected with much greater facility and more promptly than by other technics.

32. Tetany of Parathyroid Origin.—Marinesco's article is a clinical lecture on a case of intermittent tetany exhibiting several symptoms supposed to be peculiar to exophthalmic goiter. He reviews the various causes of tetany, calling attention to the fact that the thyroid body becomes hypertrophied during gestation, and that the lack of this physiologic hypertrophy is liable to entail serious disturbances. On the other hand, gestation has an unfavorable influence on already existing thyroid and parathyroid insufficiency, as has been abundantly proved by clinical and experimental research. This suggests that tetany and eclampsia may be the result of parathyroid insufficiency. This assumption is corroborated by Vassale's recent success in treatment of eclampsia with extract of parathyroid glands, chronicled in THE JOURNAL recently, page 363. Marinesco put his patient on this organ therapy and during the twenty-three days interval at date of writing the tetany had not reappeared and the other symptoms had gradually subsided. He used beef parathyroid glands and is convinced that this parathyroid treatment has a promising future in treatment of various forms of spasmodic contractions.

33. Early Surgical Treatment of Intrapulmonary Non-Tuberculous, Fluid Pockets.—Lejars denounces the dilatory way in which morbid processes in the lungs are allowed to develop unhindered. Their spontaneous irruption into the air passages and expulsion by a vomica are rare occurrences and the physician should not trust to such an event. The dangers of delay outweigh those of a vague diagnosis, and early surgical intervention should be the rule, not the last resource. It is the only means of cure in the majority of cases, and the physician and surgeon should endeavor to popularize it.

34. Retention of Urea in Bright's Disease.—Widal and Javal summarize their extensive study of this subject in the statement that chlorids and urea may be retained in the organism together or separately in the course of Bright's disease. The mechanism of their accumulation varies for each. In the course of the "uremic" state the phenomena due to the retention of the chlorids are distinct from those due to the accumulation of nitrogen in the blood. These two kinds of retention offer entirely different indications for dietetic treatment. Deprival of salt is effectual in combating the water-accumulating effects of retention of the chlorids. When the nitrogenous bodies are accumulating in the blood, ingestion of albuminoids should be reduced. Administration of from 100 to 150 gm. of lactose aids in nourishing the patient while it does not favor the development of toxic substances, and with abundance of water is liable to banish the attacks of eclampsia and the edema, as occurred in a recent case in Lemierre's experience, after four days of this lactose and water diet. The theoretic régime for a patient with retention of nitrogenous bodies would be exclusively carbohydrates and fats, substances which form merely carbonic acid and water in their disassimilation. Such a diet, however, could be imposed only for a short time, as albuminoids are necessary for regeneration of the tissues. Comparison of the proportion of urea in the blood with the proportion of albumin in the diet allows the quantity of albuminoids to be ingested to be scientifically regulated. Local or general venesection is a valuable aid in this disease, and it allows surveillance of the proportion of urea in the blood which should be systematically determined. As a general rule, however, the amount of albumin allowed in Bright's disease should be moderate but sufficient. Milk is not so innocent as generally supposed, for 3.5 liters contain about 120 cm. of albumin, that is, more than the normal man has need of. The milk supplies also too much water for certain cases. Out of 3 patients who died with an excess of urea in the blood, 2 had been on a milk diet for several weeks and one had ingested nothing but 3 liters of milk a day for the space of two years, when the first symptoms of the terminal uremia developed. It must not be forgotten that the nitrogen in the food, whether from meat, vegetables or milk, leads to the production of urea. Milk owes its value in kidney disease to the lack of salt, and Widal's experience has demonstrated that it can be advantageously replaced by substituting for 3 liters of milk, 400 gm. of meat and 500 gm. of bread, without salt, or a milk-vegetable diet which is much more appetizing. Meat in itself is not injurious in kidney disease. As a general rule, from 100 to 200 gm. of meat will be found sufficient to supply the necessary albuminoids while imparting variety to the diet. Research on patients whose blood was tested repeatedly for urea, has only confirmed the value and harmlessness of this amount of meat given in combination with starchy substances or milk. An excess of salt should always be avoided in the diet as a precautionary measure, and likewise an excess of albumin, as one never knows when accumulation and retention may be impending.

35. **Are Moral Emotions Able to Induce Organic Nervous Affections?**—Cheinisse answers his question in the affirmative, and cites a number of instances to sustain his assertion that a psychic shock under certain circumstances may induce an anatomic lesion of the nerve centers, just as it may favor the development of epilepsy, hysteria or a neurosis of any kind. He insists also on the fact that a certain interval may and usually does elapse between the emotion and the first manifestations of the consecutive nervous affection. Paralysis from fright and similar affections may be readily cured by appropriate measures, but, on the other hand, they may persist, and the prognosis should always be more or less guarded.

38. **Palliative Operation on Stricture in Rectum.**—Leuk has performed in several cases an exceedingly simple operation which apparently answers the desired purpose as effectually as the more complicated technics. His first patient was a woman of 35, with a history of syphilis. Between 4 and 5 cm. above the anus a circular stricture narrowed the lumen to 1 cm. He excised a wedge of the stricture large enough to allow the passage of feces through the opening thus enlarged. The incision was restricted to the constricting parts, and did not enter the underlying tissues. This prevented any secondary cicatrix formation and shriveling. The excision was done through the speculum without fear of hemorrhage, as Allingham has expressly declared that "hemorrhage from the rectum need not be feared." During the two years since the patient has been free from any disturbances in defecation without restrictions as to diet. The local inflammation in the rectum has been materially reduced, and the general health has improved, while there has been no further increase in the constriction. The effects were equally good in two similar cases. He urges that this simple measure should be given a trial before undertaking more complicated technic, as it is liable to prove all that is necessary, and if not, it does not interfere with more radical procedures later.

41. **Congenital Small Stomach.**—Bendersky's article on what he calls "microgastria" has already been mentioned in these columns. He has found that certain persons, always women, have an abnormally small stomach. They suffer from repeated uncontrollable vomiting, apparently of the nervous type. They are also subject to obstinate hiccoughing. He thinks the condition is analogous to the infantile uterus, and suggests that the food should be taken in small amounts. Treatment is of little use except possibly repeated lavage of the stomach, as the mucous membrane seems to be abnormally sensitive in these cases.

42. **Balneotherapy in Urinary Affections.**—Among the points emphasized by Posner is the necessity for discriminating between salt-containing and salt-free waters in treatment of urinary affections. The action of salt in inducing edema has been amply demonstrated in the last few months. Chronic catarrh of the bladder and kidney pelvis seem to be best adapted for treatment with mineral waters. Chronic parenchymatous nephritis contraindicates them. Neuroses of the urinary and sexual apparatus are often favorably influenced by a course of treatment at a watering place.

61 *Zur lokalen Sensibilisierung und Immunisierung der Gewebe gegen die Wirkung der Radiumstrahlen (tissues and radium rays). R. Werner.

47. **Treatment of Infected or Suspicious Wounds.**—Friedrich writes from Bier's clinic and states that his observation of Bier's method of treating even acute inflammations by inducing passive congestion has converted him from a pronounced opponent to an admirer, although he is waiting for time to pass final judgment on this technic. He is convinced that the adoption of physical measures in the treatment of wounds, abandoning the chemical, and striving to promote and supplement the biologic processes, is the greatest advance since Lister. In all wounds suggesting the possibility of tetanus, he advises total excision of the focus and foreign body, supplemented by preventive injections of antitoxin.

49. **Treatment of Chronic Perityphilitis.**—Albu proclaims that the indication for surgical intervention, in these cases at least, should not be the pathologic condition, but the impairment of health. He does not advise operating in chronic perityphilitis unless the diagnosis is absolutely sure, and when serious disturbances persist after careful internal treatment, including rest in bed, regulation of the bowels, wet packs, sitz baths and belladonna. He relates a number of cases which simulated chronic appendicitis but proved to be visceral neuralgia or hysteroneurasthenia, spastic obstipation or other affection, readily yielding to the above internal measures.

52. **Id.**—Boas does not regard the prognosis of chronic appendicitis as very serious, but still he advises the removal of the appendix even in the cases in which the inflammation never becomes acute. Internal treatment is of little benefit in these interminable chronic cases. Chronic inflammation developing after an acute attack should always be operated on, as also persisting disturbances in children and at the age of puberty. In the young, physical and dietetic restraint is absolutely unenforceable, and the appendix should be removed. He has never known of an instance of the complete cure of chronic perityphilitis. Sooner or later the patients return.

53. **Appendicitis and Pregnancy.**—Gauss describes 2 cases of appendicitis complicating pregnancy to call attention to the difficulty of diagnosis and the special indications in these cases. Differentiation and treatment require simultaneous gynecologic and obstetric experience with surgical and internal medical co-operation.

54. **Treatment of Incarcerated Hernia.**—Brix again calls attention to the readiness with which incarcerated hernia can be reduced after being sprayed with ethyl chlorid. He has frequently witnessed spontaneous reduction of the hernia under the spray.

55. **Cysts in Cerebellum.**—Lichtheim reports 2 cases of cysts in the left half of the cerebellum accurately diagnosed and operated on by Garré. The symptoms subsided afterward in each case with the exception of the irreparable optic atrophy.

He urges exploratory incision and prompt intervention to forestall choked disc in such cases.

56. Retention of Sphincter Muscle in Removing Rectal Cancer.—Kraske reports 14 cases which illustrate the advantages of the technic which he advocates and follows.

61. Means to Enhance Action of Radium Rays.—Werner relates the result of extensive research on the action of radium and means to enhance it. He found that the tissues reacted much more intensely to the rays when previously sensitized with injections of activated lecithin or of a solution of eosin. Still better results were obtained by a slight preliminary inflammatory reaction induced either by chemical, thermic or mechanical irritation or congestion. He became convinced that the local accumulation and destruction of leucocytes by these measures was an important factor in the result, and hence increased it by preceding leucocyte-attracting injections of turpentine or nucleic acid. He also found it possible to render the tissues more resistant or immune by a preceding prolonged irritation, refrigeration or preliminary exposure to the rays. He suggests that a combination of these various measures might materially enhance the value of radium therapy. By rendering the surrounding tissues immune and by increasing the susceptibility of the pathologic tissues, it might prove possible to increase the intensity of the exposure and to lengthen it without harm.

62. The Breslau Clinic for Children's Diseases.—Czerny protests against regarding the infant department as a mere appendix to the pediatric clinic. It should be considered the most important feature of the institution. Orthopedics and surgery have no place in the pediatric polyclinic, it should be devoted almost exclusively to children under two years of age. It should aim to keep a running record of each case and to follow the children from year to year. By this means, material of incalculable value will be accumulated, and many workers in various well-managed children's clinics can cooperate in a single task. Study of the physiology and pathology of the child during its first two years of life is the most important part of the pediatrist's work.

67. Alimentary Albuminuria.—Kaliski and Weigert fed large amounts of albumin to healthy children—as much as 24 raw eggs in two days in some instances, and 42 in three days in another. In only 2 of the entire number of children could even traces of albumin be detected in the urine thereafter. The tests with cooked albumin were all negative. They suggest as a possible explanation for alimentary albuminuria the assumption of insufficient digestion—a condition of gastric achylia. Persons in this condition should be preferred for the tests.

69. Treatment of Obesity in Children.—Orgler recommends potatoes and fluids in abundance with avoidance of fat and sauces. An obese boy on these restrictions lost ten pounds in the course of a month. The nitrogen balance was kept up or nitrogen taken in excess, as shown in the dietary appended.

70. Lime Content of Infants' Brains.—Quest announces that the proportion of lime in the brain of the fetus or newlyborn child is remarkably large, but that it soon sinks to the ordinary proportion. He is inclined to regard a deficiency of lime as possibly responsible for the increasing tendency to cerebral excitability in children. The brains of 3 children who had succumbed to convulsions showed an abnormally small proportion of lime in their composition.

75. Influence of Food on Chemical Composition of Organism.—The percentage of water is a decisive factor in artificial culture media, and Weigert suggests that this may be a factor also in individual immunity. Extensive experiments on animals demonstrated that the character of the food has a marked influence on the retention of water in the body. The proportion of water is the highest when the food consists principally of carbohydrates. Other experiences are related which lend plausibility to this view that individual immunity may be influenced by the character of the food and the consequent retention of water. The large amount of easily digested fat in the breast milk may be one cause for the relative high immunity of breast-fed children.

76. The "Exudation Diathesis."—Czerny suggests that a congenital anomaly may be responsible for various affections accompanied by exudation, such as eczema, recurring bronchitis, tonsillitis, retropharyngitis and other affections of mucous membranes. They form a group with features in common, suggesting a congenital anomaly of the juvenile organism. The course of the individual cases is determined by the character of the food, the condition of the nervous system and intercurrent infections. Avoidance of all overfeeding, a vegetable diet, excluding even eggs, and systematic disregard of exaggerated subjective disturbances and scrupulous avoidance of intercurrent infections are the most important means of combating this "exudative" diathesis.

91. Paradoxical Sweating in a Child.—The child was a girl of 6, who perspired at certain points, the back of the head, breast, etc., on exposure to cold. The tendency to this abnormal perspiration occurred at periods of a few months, with long intervals. Under arsenic the periods have become shorter, the intervals longer, and the tendency has been much reduced.

96. **Cancer of the Uterus.**—Runge sees hope for better results in the treatment of carcinoma of the uterus in further improvement of operative technic, but more especially in an earlier diagnosis of the disease. The earlier the patient comes to operation the more satisfactory the results will be. The great moral responsibility resting on the family physician, to whom such patients usually first apply, must be thoroughly appreciated. The symptoms of beginning carcinoma should be borne in mind, especially the fact that pain is a late appearing symptom, and the importance of irregular and easily induced hemorrhage. The physician should realize that, especially in cancer of the cervix, the hours are precious and a day's delay in confirming the diagnosis may be fraught with momentous consequences. He should use every effort to persuade the patient to permit an immediate examination. A piece of tissue excised should be submitted at once to an expert. If doubt exists, it is best to send the patient at once to a specialist. It is important also that women should be instructed to note every suspicious symptom and not to be misled by the idea of "change of life," etc. Midwives are often consulted, and they should be cautioned against giving an opinion on these matters, and the physician should refrain from prescribing without thorough examination. Women should be cautioned against trusting to the representations of irregular practitioners.

97. **Intravenous Injections.**—Doevenspeck can not corroborate the favorable opinion of Mendel in regard to the results of intravenous injections of salicylic acid compounds and thiosinamin. He has had much less brilliant success, finding in several cases that, after the intravenous injection had failed, other modes of applying the salicylates were successful in curing obstinate rheumatic affections. The effect of thiosinamin in removing cicatricial tissue was never striking, and the failures outnumbered the successes. The author can not, therefore, agree with Mendel that this method will constitute the therapy of the future, on account of its exacting technic and of the fact that it offers only slight advantages over ordinary methods. He thinks, however, that it is capable of more extensive application than would appear from the present reports. Extensive trials of it have been made in Italy, where the intravenous route is commonly used, and animal experiments have shown that the veins bear the introduction of considerable amounts of various medicines without harm.

98. **Iron in Stomach Diseases.**—Elsner considers it established that iron is absorbed and assimilated, and that organic combinations are the most suitable for therapeutic administration because iron is contained in the food in proteid combination. A difference in the hemoglobin-forming power of the various preparations of iron has not been demonstrated, so that the choice of the various preparations at present should be decided by their effect on the digestive organs. Elsner experimented with a hemoglobin preparation to determine its effect upon the digestive functions. He concludes as follows: Symptoms of dyspepsia do not contraindicate the use of iron preparations, but in such case functional investigation of the stomach should precede the use of iron. Iron preparations are contraindicated in organic stomach diseases, with hyperacidity or hypersecretion, and if existing dyspeptic troubles are increased by the use of the iron.

99. **Artificially Soured Milk as a Dietetic Treatment for Infants.**—Remmel has substituted for buttermilk, as a food for sick children, an artificially soured milk made by inoculating pure centrifuged milk ("skim milk") with a pure culture of lactic acid bacilli. The milk is boiled with a chemically pure preparation of starch, which causes the casein to assume a colloidal form. The best test for the success of the preparation is the smell and taste. The odor should be feebly acid and pleasantly aromatic, and the taste should be a sweetish sour, never bitter or rancid. If the stomach rejects it or the number of stools are increased, the fault probably lies in the preparation. In such cases it should be omitted for a few days and a new beginning made with a fresh preparation. Soxhlet's nutrient sugar is added to the extent of 25 gm. per liter, together with an equal amount of cane sugar and from 10 to 15 gm. of the starch preparation. When cool, the "acidifying tablet" is added. This he has found to be of the greatest advantage, as it allows the use of other carbohydrates that otherwise could not be tolerated. This food is usually well liked by children. In regard to indications for the use of the soured milk he concludes that the acute, often febrile, bacterial diseases of the intestine after a period of abstinence, furnish an indication for the sour milk diet, with the exception of intestinal troubles caused by a too rich carbohydrate diet with fermentation and slimy stools. It is still more necessary, however, in chronic nutritive disturbances from the lightest dyspepsia with relative hypochylia, to the most severe, often apparently irreparable atrophy with extensive disturbance of metabolism. He suggests its use for adults in metabolic disturbances (diabetes and gout), as well as in gastrointestinal diseases and tuberculosis, and as a convalescent diet on account of its being rich in albumin, easily digested, and cheap.

COLOHEPATOPEXY OR COLON SUBSTITUTION.

A NEW OPERATION FOR PERIGASTRIC ADHESIONS AFTER GALLSTONE OPERATIONS.

E. WYLLYS ANDREWS, M.D.
CHICAGO.

All postoperative adhesions after gallstone operations do not cause trouble. In many cases no pain or disturbance results from numerous firm bands uniting stomach, liver and colon. In others there are disturbances of great variety, ranging from slight dragging to severe pyloric compression, torsion of the pars pylorica, hour-glass stomach, dilatation, vomiting, and evidence of outside pressure on the liver ducts, even to the extent of causing jaundice and hepatic colic. There may even be symptoms simulating recurrence of gallstones.

With the increase of gallstone surgery, the disposal of the viscera after operating so as to avoid gastric deformation by adhesions will have to be given much more serious attention, or else a series of operations will have to be performed to relieve deformities almost as distressing as the original disease.

As adhesion building is normal to gallstone surgery, it must be ascribed to luck and accident rather than to forethought that so few of these sequelæ occur.

This risk may be understood more clearly by considering, so to say, the geography and orientation of this corner of the abdomen. There is no part of the cavity which has such invariable boundaries as the gallstone surgical field. Unlike most parts, it is not subject to the floating in or intrusion of other viscera. Its surroundings, to a certain extent, shut it off and prevent it from draining into or out of the rest of the cavity. In form it is a triangle, bounded above by the liver and appendages, below by the colon and mesocolon, and to the left by the stomach, gastrohepatic omentum and duodenum. Of course, the pylorus lies somewhat behind and partly between the colon and the liver. The triangle is a potential cavity only. As soon as retractors are introduced, the triangular form of the space is developed. This space can also be conceived as a spherical triangle, or as a pyramid, with its base on the abdominal wall, and its apex in the foramen of Winslow. The left border of the cavity is made up of the pars pylorica, pylorus, gastrohepatic ligament and duodenum in a line, having its center somewhat immovably fixed by the second portion of the duodenum.

This potential space, which I have ventured to call a "triangle," really becomes such when it has been filled with drainage tubes and gauze strips after operation. It is between the above mentioned organs and seldom any others that postoperative adhesions form. Of course, the mesocolon and the various omenta play an important part by interposing their layers. The greater omentum often rises to help fill this space, and I have sometimes encouraged this tendency by using it to cover the colon and pylorus. Either with or without such interposition, the result of operation and drainage, or of pericystic inflammation alone, is the obliteration of this "triangle." As long as the present methods of operating continue, the occurrence of these adhesions must be expected. It is not clear that it would be desirable to prevent them. They are, in fact, an end to be sought, necessary and life-saving, in all abdominal work not strictly aseptic; the only thing which makes transperitoneal drainage practicable. They are even more life-saving when perforation and pericystitis have occurred without operation, a thing much more common than was formerly recognized.

We, therefore, expect, with or without previous operation, that many cases will show the colon, liver base or edge and stomach end agglutinated into a mass around the gall tracts. It is easy to estimate that in most instances no bad symptoms are caused by these adhesions. Fortunately, most gallstone patients leave us cured. The minority which fail of relief, or are made worse, may be divided into three classes:

1. Those cases in which no stone was found; or, in other words, in which mistakes in diagnosis had been made.
2. Those cases in which some of the stones were overlooked.
3. Those cases, successful in other respects, in which perigastric adhesions and deformity appear to keep up the gastralgia.

This unpleasant minority should be studied carefully from every possible standpoint. In proportion as the adherent masses are deep and posterior, they are less troublesome, since they concern parts normally fixed by omentum and less mobile. In some cases, it is as if the gastrohepatic omentum had merely extended its attachments and been fortified by the gastrocolic or the greater omentum and the mesocolon, which had thrust themselves into the diseased area. The only effect of this is to anchor the first portion of the duodenum and colon a little more firmly than usual, while the pars pylorica is still free to rotate as the stomach distends, and no outside pressure is felt on the pyloric ring.

It is far different when the anterior wall or either curvature of the stomach becomes seriously entangled with the gall bladder, liver edge or abdominal wall (Figs. 1 and 2). We can best realize what gastric pain and functional disturbance this can produce by recalling the different anatomic relations of the full and empty stomach, as demonstrated by Symington. The empty viscus has its right end near the middle line. The distended stomach moves several inches to the right by rotating around the second portion of the duodenum, which has little motion. The pylorus, he shows, moves more than the duodenum, and the pyloric part of the stomach is more movable than either. In other words, the full or dilated stomach rises into the cupola of the diaphragm and then rotates until the pylorus is pushed over against the gall bladder. The pyloric end of the stomach then overlaps the less movable pylorus, forming the so-called antrum pylori of Schaefer and Symington. It finally takes such a position that what was the anterior wall faces, first, outward, then even posteriorly, lying in contact with liver and gall bladder in a wholly new relation. It is when adhesions form in something like this right-sided relation that I have found gastralgia and loss of function curable by operation. On the other hand, when adhesions form chiefly between the colon and gall passages, or liver edge, no matter how dense and wide they are, I have never known of any trouble to result from them.

Lauenstein[1] gives some drawings of these adhesions to several viscera.

Since writing the foregoing I have seen the short but interesting paper of Dr. Robert T. Morris[2] on what he calls "gall spiders" or weblike adhesions around the gall tracts after inflammation, e. g., cholecystitis, gastroduodenitis, diaphragmatic pleurisy, etc. Morris lays stress on the factor of dragging on the great sympathetic ganglia. He also attributes cases of mucous colitis and diarrhea to colon adhesions. He advocates the breaking up of these adhesions and the use of Cargile membrane, or aristol powder, to prevent them from reforming. The paper shows great insight and cleverness in a new direction.

My own conclusions, based on five operations, are rather at variance with this. I have already stated that I regard postoperative and preoperative adhesions as necessary and desirable. In a great number of gall-tract adhesions between liver, colon, gall bladder and duodenum, I do not recall any instance of angulation of the cystic duct or apparent dragging on the sympathetic ganglia, nor any of mucous colitis due to bands. The trouble I have seen has always been from gastric disturbance, and then only when the anterior wall or one border beyond the pylorus became involved.

I also differ entirely with Morris regarding the technic of removing these adhesions. I have no faith at all in Cargile membrane or in aristol to prevent their reforming. There is, in fact, no problem more difficult to me than that of breaking up large adherent areas between liver, colon, stomach and pylorus, and then preventing their reunion.

My own solution is not to try to prevent them, but simply to let them readhere in a more advantageous relation.

In each of the cases given below, the stomach was the organ deformed, and in the same manner each time—by too extensive union to the liver. The problem, on opening the abdomen, was not so much how to release the adhesions as how to prevent their reforming in the same position. While it is true that long bands can be cut and not reunite, flat or broad adherent surfaces must grow firmly together if left in contact. The interposition of anything like foil or membrane will only increase the density of these adhesions, just as gauze packing does.

It is in our power, nevertheless, to rearrange the position of these three movable organs so as to exclude any one of them and to make the union chiefly between the other two. Thus the stomach can be released entirely from the liver false attachment at the expense of the colon, which will then take its place and become adherent to the liver adhesions.

The operation I now practice is precisely this, substitution of the colon for the stomach after the latter has been dissected from the liver, and might be called colohepatopexy or colon substitution. I employ sutures to maintain it in this new and false, though harmless, position. As this technic has been evolved from several tentative efforts, and has worked admirably in curing the stomach distress, I feel like advising it in all similar cases. Doubtless cases of bands or of Morris' "gall spiders" may also be met, and may be treated by simple division, as he suggests. I have not seen many cases except of the stomach type, and in those I do not think anything but colon transposition will give relief.

1. Incision about the middle of the right rectus or nearer the middle line if an old scar is to be avoided. Plenty of room is required.

2. Careful study of the shape, position and mobility of the stomach will disclose in a typical case numerous short bands or a broad connection uniting the liver edge and a large part of the pyloric end of the stomach, as well as the lesser curvature or anterior wall. In Case 3 (Fig. 2), the attachment of about an inch of the greater curvature caused a degree of hour-glass contraction at a point two inches from the pylorus. In the other cases. the union was between broad surfaces from the gall bladder to the middle line.

3. The most careful separation of the liver from the stomach should be made, and, if necessary, the liver tissue rather than the stomach wall cut and lacerated in the dissection. Bleeding can be checked by hot sponges in the usual way if ligatures are not applicable. The pylorus should be examined by invaginating between thumb and forefinger, to demonstrate that gastroenterostomy or pyloroplasty is not needed.

4. It will be found that the separated viscera will fall back into intimate contact, and that there is no safe way of drawing the stomach to the left and anchoring it. The transverse colon is, therefore, pulled up with any loose omentum which is present, and thrust into the space between liver and pylorus. This is not so much of a displacement as might be supposed from a written description. The bowel is not rotated and does not cross over the stomach, but only forces it toward the right. It is practically the same position which the hepatic flexure assumes after gall-tract adhesions in average cases. To hold the colon in this new relation, its omenta are stitched to the gastrohepatic ligament, liver surface, or such adhesions as form the angle between pylorus and liver. With ordinary care, tissue can be found to sew to without endangering the ducts or large vessels of the liver or of the bowel wall. The more loose omentum can be interposed the better. Of course, a colon suspension incidentally is done here, which cures at the same time any prolapse of the stomach which may be present.

In the following cases the patients have been operated on by this method:

Case 1.—Mrs. H., aged 43, was operted on for gallstones November, 1904, by Dr. McArthur. She was greatly improved as to colic and icterus, but returned for gastric distress, most severe after eating, with some atacks of vomiting and constant sense of weight in epigastrium.

---

[1] Int. Surg., p. 367.

[2] Medical Record, March. 25, 1905.

Operation.—Laparotomy, Jan. 18, 1905, showed dense adhesions between the pyloric part of stomach, including about one-third of the lesser curvature and the liver edge for three or four inches. The gall bladder fundus seemed covered by and adherent to the stomach. The liberation of the stomach was somewhat tedious. After drawing it away from the liver it would immediately fall back in contact when released. The colon, which was nearly free, was drawn up and held against the denuded liver surface by three catgut stitches, one of which was deep and included some of the gastrohepatic omentum.

Result.—Complete relief of gastralgia and digestive trouble followed at once, and the patient made a rapid recovery. She has since had no recurrence of gallstone or stomach trouble.

Case 2.—H. S., male, aged 29.

History.—Three years ago he had a gallstone operation, performed by Dr. Frank T. Andrews. He has remained free from hepatic colic, but gradually has acquired a form of gastric functional disturbance, causing dragging pain, anorexia and pain after eating.

Operation.—The operation, February, 1905, was identical with that in Case 1. Less trouble was found in releasing the adhesions, which were mainly between the anterior and upper border of the stomach and the edge and under surface of the liver. The colon was made to take the place of the stomach by attaching it to the denuded liver.

Result.—Permanent relief followed this interference.

Case 3.—H. T., male, aged 33.

History.—Dr. Davis referred patient for chronic gastralgia and dragging pain. No splash or typical signs of hour-glass stomach were present. There was absence of organic acid and normal free hydrochloric acid. He never had boring pain, bleeding or hyperacidity. There was no history of cholecystitis. No operation had been performed.

Operation.—On abdominal section the main adhesions were found between the upper border of the stomach and liver border for about three inches. The greater curvature was also attached by a band at one point about three inches from the pylorus, and thus looped up, constricting the stomach at that point. The colon substitution was performed February, 1905, and the patient had entire relief as long as he was under observation.

Case 4.—Mrs. T. O., aged 57.

History.—The patient has had numerous attacks of cholecystitis, with sepsis, during two years; no jaundice or true colic. There has been some constant pain in the gall-bladder region and in the right shoulder. I removed the gall bladder, which was greatly enlarged, November, 1903, finding no stones. Periodically since then and for the past six months constantly there has been dragging pain, anorexia and occasional vomiting.

Operation.—Operation showed pylorus immovably fixed to liver, gall tracts and colon by firm union of flat surfaces, but no long bands which could be cut. After stripping and dividing these adhesions, the pylorus and stomach were pushed well to the left, and the colon lifted up and anchored between them and the liver by its omenta.

Result.—Immediate relief was obtained, which continued for the three weeks she remained in the hospital. I have not had a report since.

Case 5.—Mrs. O. D., aged 36.

History.—Two years previously she had an operation for pelvic disease, appendix removal and gallstones at one time, by Dr. Graham at the Presbyterian Hospital. One year later she began to have pain in epigastrium, generally after eating. She would vomit partly digested food. There was no blood or bile in vomitus. She had acid eructations and some pain radiating to the right shoulder blade. Drugs, lavage and diet regulation gave slight relief. There has been, since first operation, no icterus or biliary colic, and no tumor or soreness over the gall bladder.

Operation.—May 30, 1905. An incision was made through the old scar, the usual gall-bladder incision, about four inches long. The omentum was adherent all along the old scar; the adhesions were quite firm and dense all through the right hypochondriac region and around the gall bladder, and extended posteriorly along the ducts. One distinct rope-like adhesion, which was very firm, drew the anterior stomach well over to the gall bladder and upward toward the liver. This adhesion twisted the pyloric end of the stomach and the organ was dilated considerable; palpation showed no pyloric obstruction. The gall bladder had been sutured to the peritoneum in the previous operation. It was hour glass in shape and contained three stones the size of a pea. The coats of the viscus were slightly thickened and inflamed.

Technic: Adhesions were broken up or ligated and cut, the rope-like adhesion drawing the stomach to the right was freed. The gall bladder was opened and the stones removed. They were soft like putty. To prevent the stomach from again becoming adherent to the gall bladder the transverse colon was drawn up (the stomach being pushed to the left), and sutured between the gall bladder and stomach under the liver. Three catgut sutures were used. Omentum was also spread over the old adhesions and the abdomen closed in the usual manner. A Mayo drainage tube was put in the gall bladder with pursestring suture of catgut.

Result.—A marked relief from vomiting and stomach distress was obtained at once. The patient on one or two occasions had vomited after improper eating without permission, but is quite relieved of the old distress.

In all these cases, gastric lavage was first tried ineffectively. The symptomatology was fairly distinct, because of the history of gall-tract inflammation or of operation, the prominence of pain, and dragging sensation, and the absence of hyperacidity or signs of pyloric obstruction. I debated the propriety of gastroenterostomy as a remedial measure in each of them. It is possible that such a drainage would have done good, but probably less good than the method used.

CONCLUSIONS.

1. Gall-tract adhesions are inevitable after disease and operation.
2. They are beneficent, harmless and symptomless in all but a few cases.
3. These few represent malposition rather than trouble from adhesions *per se*.
4. The colon, gall bladder, duodenum and pylorus can adhere to each other without impairing their function. The other parts of the stomach cause trouble if involved.
5. Such adhesions will reform when separated, unless the colon be substituted for the stomach.
6. The causing of colon adhesion to the liver does not disturb its function perceptibly.
7. Probably certain vague gastric disturbances have been treated by gastroenterostomy when the patients would have had more benefit from this operation.

THE TREATMENT OF EMPYEMATA OF THE MAXILLARY SINUS THROUGH THE NOSE.*

GEORGE L. RICHARDS, M.D.
Otologist and Laryngologist Fall River Union Hospital.
FALL RIVER, MASS.

The questions of etiology and differential diagnosis are considered in this paper only so far as they have direct bearing on the proper treatment.

ETIOLOGY.

Empyemata of the antrum may be divided etiologically into two classes.

In the first class are those cases which originate in diseased processes in the tooth roots or which occur in connection with and as a result of pathologic processes around the tooth roots and are said to be as a whole cases of dental origin.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

In the second class of cases, which increasing experience is showing us to be much the larger of the two, are those empyemata of the antrum due to nasal conditions. The epidemic form of influenza known as grip, is by far the most common cause of the acute empyemata, whereas old, long-continued inflammations, ethmoidal or frontal, or any other nasal cause which interferes with the natural drainage of the antrum through its natural or acccessory openings, are responsible for the chronic cases.

DIAGNOSIS.

This must be made with reference to the etiology, as far as it can be determined. Exploratory puncture with the trocar beneath the inferior turbinate is the simplest method of determining the presence or absence of pus. A study of the nasal conditions and a study of the tooth conditions will usually determine which factor is the one at fault. It will often be found advantageous in cases of doubt to have a consultation with a dentist.

TREATMENT.

Originally, nearly all antral empyemata were drained through a tooth socket and the entire after treatment kept up through the opening which resulted from the extraction of the tooth, with the result that many patients were compelled to wear tubes of various sorts, rubber, gold or silver, for varying lengths of time, weeks, months or even years. As this treatment failed in a large majority of instances, the next operation which came into vogue was the more radical one of opening through the canine fossa, removal of the mucous membrane of the antrum with thorough inspection of the cavity, accompanied with a counter opening into the nose and the immediate or subsequent closure of the canine fossa opening. This procedure effects cures but in many instances is probably a more extensive operation than is absolutely necessary.

In recent years, many rhinologists, finding that the washing out after exploratory puncture underneath the inferior turbinate, when continued for a certain length of time, not infrequently effected cures, especially in acute cases, have been led to study more thoroughly the possibilities of treatment of these empyemata by purely nasal methods. Among these rhinologists are Freeman of Philadelphia, who published some years ago an important article on the treatment of these empyemata and introduced a trocar and canula; the chairman of this section, Dr. Myles, who has a trocar and canula for perforating the antral wall; Mikulicz, Curtis, Claoue, and the secretary of this Section, Dr. Freer. I have been using this method for several years, having been led thereto as a result of trying Dr. Freeman's method some years ago, which, though imperfect as to its instruments, was still a step in the right direction.

There is a large class of cases of empyemata of the antrum in which the antrum is merely acting as a reservoir for pus and in which the antral mucous membrane is not of itself particularly degenerated. Such cases are especially adapted to treatment through the nose, which is the natural drainage point of the antrum. The mouth is an abnormal drainage point, and any opening from the antrum into the mouth is in constant danger of being infected from the mouth, no matter how thoroughly clean it may be at the time of operation. Whenever it is necessary to make such an opening, as in cases of simple empyemata of dental origin or after the radical operation through the canine fossa, an endeavor should be made to close it as soon as possible and permanently to separate the cavity of the antrum from the cavity of the mouth.

In the presence of antral disease the course of procedure should be somewhat as follows: If the infection is of dental origin the tooth should be extracted and the infection treated. The opening should be allowed to close as soon as possible. In the presence of symptoms not suggestive of dental trouble or when in doubt as to the origin of the antral disease, an exploratory puncture should be made high up underneath the inferior turbinate at the junction of its middle and anterior thirds or over the inferior turbinate near the natural orifice of the maxillary sinus. A curved canula, with or without trocar answers very well for puncture underneath. The only point to be especially noted is the exact point at which to enter the trocar. In ordinary shaped faces the junction of the anterior and middle thirds of the inferior turbinate answers very well. In patients in whom the malar bone is set rather far back on the face and the nose is relatively long, one should go a little further back, as otherwise there is some danger of perforating a little too far forward and even of entering the cheek. The right-angled, sharp trocar needle of Killian does very well to make an opening for diagnostic purposes. It is entered in the middle meatus just above the line of the inferior turbinate, where the bone is usually very thin. I generally use a stout, bevel-edged needle trocar, or that of Killian. The antrum is then washed out. The next step in the treatment is to continue this washing out of the antrum for a few days and see if it will not be sufficient to effect a cure. The opening can be readily found with a curved Eustachian catheter slightly smaller than the caliber of the trocar canula, or the same instrument can be introduced each time the antrum is washed out. The pain of this procedure is very little when a 20 per cent. solution of cocain combined with adrenalin is used.

If discharge of pus still continues, simple washing through the small opening will probably be insufficient. A probe passed through the opening will give some information as to the character of the antrum. If the cavity seems large and roomy and the mucous membrane does not feel particularly boggy, the presumption is that a cure may be obtained by simple washing. If at the end of a longer or shorter time, a week or more, the simple washing is followed every day by discharge of pus, not diminishing much in quantity, it becomes evident that better drainage must be obtained. The next point is to enlarge the opening into the antrum sufficiently so that it will remain open during the required time of treatment. The naso-antral wall is thinnest just above and just below the insertion of the inferior turbinate, while thickest on the absolute floor of the nose. It is desirable to get the point of drainage at the lowest possible point since in the main the patient maintains the head in the erect posture and the drainage is therefore the better.

The question then arises whether to make it above or below the inferior turbinate or to remove the anterior portion of the inferior turbinate itself. Opinions differ as to which method is the most desirable. Many operators remove a portion of the inferior turbinate. It seems to me, however, that this bone has a valuable function in the nasal economy and that in nearly all instances a sufficiently large opening for drainage can be obtained underneath or above it without in any way interfering with it unless it be enormously large and swollen. My method of procedure is to introduce through this opening first a curette of about the same size as the opening and then a series of curettes, each a little larger than the one immediately preceding it, until I have a good-sized window into the antrum. As the bone is relatively thin, this can be done without much pain under the influence of 20 per cent. cocain and adrenalin solution, or powdered cocain introduced on the tip of a moist cotton swab. As soon as this window is made, I cut away backward with some form of alligator cutting forceps (I like those of Dr. Myles as well as any, or the bone forceps of Dr. Kerrison), until I have a good-sized opening into the antrum, so large that the largest size Eustachian catheter or other tube can be passed without difficulty. The opening can then be further enlarged so that the cavity can be packed with gauze, and if one has curettes of various sizes with long shanks a good portion of the mucous membrane of the antrum may be curetted.

If unable to work satisfactorily underneath the inferior turbinate, the opening can be made above that bone, and in some instances I think it would be a good plan to have an opening in each place, so as to permit of the best possible drainage. The cavity is then washed out by the physician daily, or as often as may be necessary; intelligent patients can soon be taught to introduce the curved canulæ so as to wash out their own antra.

Should the antrum show evidence of polypoid degeneration, or if the condition does not improve after a reasonable length of time under this method, any nasal operation alone will be insufficient and nothing less than the radical operation through the canine fossa and the removal of the entire mucous membrane of the antrum will bring about a cure. By far the greater number of patients who come under the care of the rhinologist can be treated through the nose.

Should there be at the same time, as I believe is occasionally the case, a tooth the point of which is in the way, I would have the tooth extracted just as if the trouble were absolutely of dental origin; but the after-treatment should be continued through the nose alone, the opening in the alveolar process being allowed to close, as drainage through the nose is so much less disagreeable than through the mouth and the after course of treatment is much shorter.

In regard to the choice of instruments, almost anything that will make an opening through the naso-antral wall will answer. Individual operators have their own choice. Whatever the physician may happen to have in his own armamentarium that will answer the purpose is a sufficiently good instrument. If one is familiar with the drill, either the small drill or the trephin drill described by Dr. Freer, or the instruments of Dr. Wells, of Washington, of which the trocar itself is a reamer, may be used. What is necessary is to make with the least pain to the individual a large opening from the antrum to the nose, as near forward as possible, above or below the inferior turbinate. If it seems desirable, the anterior end of the middle turbinate may be removed, thus making a very large opening, as described by Dr. Freer in his recent article, an opening large enough to drain thoroughly the cavity and to allow the introduction of any therapeutic measure which may be indicated in the individual case.

The choice of remedial agents for washing, etc., I do not take up. The point I am considering is a method of treatment rather than a detail.

The following cases of my own will illustrate the points which I have made:

CASE 1.—Mr. Y., aged 37, complained of catarrh, with some pus discharges for a long time. I made an exploratory puncture under the inferior turbinate and washed out through the canula several times. As the discharge of pus continued, I cut away a portion of the naso-antral wall with cutting forceps, underneath the inferior turbinate. I taught the patient to wash out his own antrum. In a short time he was well.

CASE 2.—Miss H. came to me, complaining of pus in the nose which had lasted for some time. She had a decayed second bicuspid, which was extracted; there was an old inflammation at the root, but it did not penetrate the antrum. The antrum was drilled into from the tooth socket, but this opening closed in two days. At the same time, the exploratory opening from the nose into the antrum was enlarged with curettes and cutting forceps. The antrum was washed out daily, first by me and then by the patient herself. Rapid improvement and cure followed in a few weeks. This opening has remained ever since. I saw the patient thirteen months after the operation, washed out the antrum and found it to be free from trouble.

CASE 3.—Mr. V. came to me, complaining of severe head cold. Simple methods of treatment, with washing out of the nose, were continued for some time without much result. I then punctured first one antrum and then the other, finding pus in each. I washed out the antra through the canula trocar opening without much of any result for about ten days. Then with curettes and cutting forceps I enlarged the opening into each antrum, with prompt improvement in drainage, subsidence of all symptoms and rapid cure. Time required, from two to three weeks.

CASE 4.—Mrs. B. had an attack of the grip, following which she was very weak—confined to bed. There were symptoms of pus absorption. I was called by the attending physician to see if there might not be some trouble with the nose. I made an exploratory puncture and found pus in the antrum on one side. The antrum was washed daily through the small opening for a few days, but with no result. I enlarged the opening with curettes, and daily washing for about three weeks resulted in a perfect cure and subsidence of all the symptoms indicative of pus absorption.

I do not mean to intimate that all cases of empyemata of the antrum can be cured by this method. An attempt to cure in this manner in no way prejudices any further operation, but rather prepares for that and shortens the period of after-treatment. I have had cases,[1] in which the more radical operation has been required, and I expect to have such cases in the future.

CONCLUSIONS.

First determine whether the case is of dental or of nasal origin. If of dental origin, treat it accordingly but do not continue, by tube or otherwise, a long-continued course of treatment through the mouth. If of nasal origin, treat in the manner described. If in doubt, treat through the nose, letting the tooth alone unless it seems to be troublesome. Even this method of treatment do not continue indefinitely if the pus continues to be a source of trouble, but do the radical operation through the canine fossa, a description of which does not come within the province of this paper. Lastly, see whether there is a co-existent empyema of the frontal sinus which may be draining into the antrum and keeping up the discharge of pus.

---

[1] "The Relative Frequency of the Dental and Nasal Origin of Antral Empyemata." Ann. of Otol., Rhin. and Laryn., March, 1905. "The Significance of Pus in the Nose with Special Reference to the Affections of the Accessory Sinuses and Their Proper Treatment," Med. News, Dec. 24, 1904.

Professor Gerber of Königsberg[2] recently published a short but lucid article on the principles of treatment in empyemata of the antrum, which are so in accord with my own experiences in this regard that I wish to translate his conclusions somewhat freely and to incorporate them in this paper. He states that he has tried all the various methods which have been advocated and has finally come to the following conclusions, which will govern him until such time as something better may be brought forward. In dealing with diseased antra of Highmore, the following principles should govern the choice of a method of treatment:

First.—Whenever possible, direct the treatment to the point where the antrum has its natural communication with the nose, and especially avoid any long-continued direct communication with the mouth or pharynx.

Second.—In cases which are not severe, the antrum is washed out in the beginning through a sharp canula introduced in the middle meatus.

Third.—If the empyema has lasted a considerable time and the secretion is thick, with considerable odor, this opening in the middle meatus is next enlarged, the so-called supraturbinal resection of Onodi being performed, to include also the inferior meatus, if it be necessary.

Fourth.—In chronic and severe cases it may be necessary to make a large opening from the canine fossa, the so-called radical operation, but this opening, after thorough inspection and cleaning out of the cavity and the making of a broad counter opening in the middle meatus, is carefully closed and the after-treatment entirely performed through the middle meatus.

Fifth.—The only patients who can not properly be treated in this way are those in whom there is a high degree of nasal stenosis, rendering this treatment impossible, and those who will neither continue in daily communication with the physician nor learn to apply themselves the after-treatment through the nasal fossa.

DISCUSSION.

Dr. Otto T. Freer, Chicago, said that the intranasal operation for empyema of the antrum needs a champion, as most men are in favor of operating by the alveolar route. Dr. Freer thinks that the intranasal operation advocated by Dr. Richards and himself is the most rational one and that it will soon displace all others for the relief of chronic empyema of the maxillary antrum. He said that the trend of late years has been to employ the Caldwell-Luc method of operation through the facial wall of the superior maxillary bone but that this is a far more formidable operation than the intranasal one, as it includes a long incision severing the lip from the alveolar process, an opening in the thick bone of the upper jaw in front, the need of a general anesthetic, and the making of an unnatural opening between the antrum and the oral cavity; besides the usual shock and pain caused by a severe operation. In the majority of cases, he said, the result is no better than that obtained by opening the antrum by the intranasal route, while the latter operation inflicts much less injury on the patient. He agreed with Dr. Richards that the opening through the nasal wall may be made of varying sizes, from a mere puncture with the trocar to the removal of nearly the entire inner wall of the antrum. Dr. Freer's technic includes the use of an electric motor and should this for any reason fail to work, the operator could fall back on Dr. Richard's method, for a combination of the best features of both ways of operating will probably give better results than either alone. Dr. Freer has never seen bad effects from the removal of the inferior turbinated body, though he has often heard them suggested. He has frequently removed the lower one-third of the lower turbinated body and has not encountered the permanent crusting and scabbing supposed often to follow this reduction in size of the turbinal, nor has he encountered rhinitis and pharyngitis as a result, and he does not think that the lower turbinated body is as physiologically important as it is supposed to be. For this reason he does not hesitate to resect its anterior two-thirds in performing a radical opening of the antrum through the nasal wall. Resection of the inferior turbinate is also a part of the Caldwell-Luc method and its followers do not speak of bad results following. The Wells rasp seems to Dr. Freer to be a good instrument, for in ordinary mechanical work he has found that a rasp cuts nearly as well as a saw. When the empyema of the antrum is not yet chronic, and when there is but a moderate purulent or seropurulent discharge, the middle meatus offers sufficient access to the antrum and an opening here may be made with the greatest ease. Onodi enters the antrum in this place with a forceps-trocar, whose blades he spreads to make a preliminary opening. This opening he then enlarges to nearly the size of the meatus.

Dr. W. S. Bryant, New York, stated that he puts most reliance on opening through the middle meatus alone, removing if necessary part of the middle turbinate. He uses a probe to locate the natural opening and follows that with a curette, after which he uses one of the angle punches and takes out as much bone as is necessary. The quantity of bone to be removed is in proportion to the bad condition of the mucous membrane, according to whether the drainage must be absolute or need be only relative. After a sufficient opening is made, washing is unnecessary.

Dr. Gardner Perry Pond, San Francisco, said that he has been very much interested in this subject because of Dr. James G. Sharp's work on the accessory sinuses. Dr. Pond has been an advocate of the nasal route and Dr. Sharp of the canine fossa route. As an argument in favor of his method Dr. Sharp quotes the relative frequency with which a double cell is found—the antrum divided by a thin bony wall. In such cases the cell nearest the nose may be opened with the cannula and the operator may not suspect the existence of the other cell, consequently there will be no relief of the symptoms. If, on the other hand, the antrum be opened through the canine fossa, and the opening be made large enough to admit a finger, it can easily be determined whether or not there are two cells. Dr. Pond stated that there is no doubt in his mind that the best drainage is obtained through the floor of the antrum and said that he can see no reason for choosing the middle meatus as a route for entering that cavity.

Dr. L. C. Cline, Indianapolis, stated that he has had considerable experience in the treatment of these cases, particularly some time ago when there was a great deal of grip in the country. Each case is a law unto itself, and that must be remembered in operating. In the old neglected cases a radical operation is necessary; in the subacute or chronic cases of short duration, recovery will often take place if the opening is made through the alveolar process. Dr. Cline does not believe in cutting away the turbinated body unless it is necessary. Drainage is necessary and to get good drainage the anatomical relations in these cases must be borne in mind. Different skulls show marked variations in the size of the cavities. Dr. Cline has often practiced making an exploratory puncture in order to measure the distances. If the tooth is out—and often it is better that it should be out, because so often it is diseased—then it is easy to make a puncture with a sharp drill. Then he cuts with the burr in various directions. This enables him to examine the cavity for polypoid conditions and to determine whether or not a radical operation is necessary. It is a simple procedure. The field can be cocainized and the work done without general anesthesia. Dr. Cline does not believe in making an opening between the superior and the middle turbinated bodies, because then drainage can be obtained only with difficulty. With good drainage and cleansing, these patients, as a rule, will recover.

Dr. C. F. Welty, San Francisco, declared that these patients can be cured by one of these various procedures, so that the question arises as to which one of the routes shall be selected as the best. This can best be done by studying the individuals. The question naturally arises, which does the least harm to the patient. Dr. Welty is firmly convinced that least harm is done by the alveolar route. He has never seen any harm follow the removal of the anterior half of the inferior turbinate, however, but his experience, he said, is limited. All the patients he has operated on by that method have recovered completely. When operated on by the alveolar route they have not recovered so readily. Radical procedure cannot be determined on absolutely until some of the more conservative measures have been used and have failed. Sometimes puncture will cure the patients. Dr. Welty has seen a number cured by a single washing out through the inferior meatus. Hajek is a great believer in the alveolar route. About two years ago he began to use the inferior meatus route. Dr. Welty does not know with what ultimate results. The route by the middle meatus should be condemned from its anatomic relation.

---

[2] Archiv. für Laryngologie and Rhinologie, vol. xvii, part I.

Dr. W. S. Anderson, Detroit, Mich., said that if possible, he should always try to save the inferior turbinated body.

Dr. S. L. Ledbetter, Birmingham, Ala., said that the question arises as to whether a given case is chronic or acute. In all the acute cases, he has found that the patients get well readily after a small puncture and one or two washings. The dentists in his section of the country get the majority of the acute cases; the patients go to them because they have some trouble with the teeth. In the chronic cases, when the lining membrane is diseased and in which there is often a polypoid condition present, recovery may not be secured by simple washings. These patients require the application of some remedy that will destroy the diseased condition of the sinus. This cannot be done without an opening sufficiently large to enable the physician to enter the cavity, which is not always regular and smooth, and to reach all the different portions of that cavity with a probe or applicator. Dr. Ledbetter does not believe that all the points can be reached as readily through the nose as through the canine fossa.

Dr. A. G. Greenstreet, Seattle, Wash., declared that the opening above the inferior turbinated is often referred to, but that very few advocate that route. He saw a case recently in which nature had performed a successful operation by that route. An old man had been suffering for several nights. When he consulted Dr. Greenstreet one side of his nose was full of pus, and in wiping the pus away Dr. Greenstreet got into the antrum above the inferior turbinate. The opening was a large one, so that he could swab the pus out of the antrum. Under antiseptic irrigations the patient was cured up in a short time. It seems to him that in many cases that might be a good route to adopt, for it obviates the necessity of resecting the anterior third of the inferior turbinate body.

Dr. DeVilbiss, Toledo, stated that in long standing cases a radical operation is needed. The cases in which the accessory sinuses are involved are those that have tried his soul the most. In acute cases an exploratory puncture for diagnostic purposes, with simple drainage may be all that is necessary, but in those cases that have lasted for a long time, in which there probably is disorganization of the tissue, whether the operation be through the canine fossa or through the inferior meatus, an opening should be made large enough to permit the introduction of the little finger. If the antrum is found to be in fairly good condition in a case of long standing, the physician should look to the sphenoidal sinus, the ethmoid cells and the frontal sinus. He mentioned a case in which Dr. Myles operated through the nose and the patient did well, but Dr. DeVilbiss usually operated through the canine fossa. He elevates the lip and with a hand trephine bores through the canine fossa and then uses a rasp or drill to enlarge the opening.

Dr. J. H. Martindale, Los Angeles, said that the views held in the different parts of the country seem to give these cases different interpretations. In Los Angeles he does not have an opportunity to treat acute cases, for in southern California there are few such. The cases he has are chronic cases, and in these cases he prefers to enter through the alveolar region if a tooth is absent or through the canine fossa if a tooth is not absent. He does not object to a permanent opening. The opening should often be large enough to permit the introduction of the little finger. It is of no importance, practically, whether the antrum be converted into a part of the oral cavity, provided it can be thoroughly washed out. The method advocated by Dr. Richards, he said, is probably of very great value in a climate where acute cases occur frequently, or where an exploratory operation may be required.

Dr. Robert C. Myles, New York, said that this subject is intensely interesting to him from a purely scientific standpoint, since he has operated in the last fifteen years by every method that has been suggested. He believes that the antrum of Highmore should not be treated after the ordinary rules of surgery. There are thin walls covered by thickened mucosa, and the general surgeon, following the ordinary rules of surgery, would advise curetting thoroughly. Dr. Myles claims that by curetting a worse condition than before is brought about. The normal mucosa is destroyed and part of the periosteum, and there is a large opening into the mouth. A new membrane can not form very soon. If curettement has been as thorough as many writers direct there is practically nothing left. The opening will contract before there is complete obliteration, and all who have tried obliteration of the cavity have abandoned it. A large opening into the nose is frequently made in these cases and the opening in the mouth allowed to close up. So there really is no radical operation. Any operation that leaves a pus cavity in an accessory sinus is not a radical operation. Dr. Myles would endorse the mildest operation that gives the best results, and that operation is a part of the so-called radical operation. The removal of the nasal wall of the inferior meatus is the most essential part of any operation on the antrum of Highmore. He has practically abandoned operating in acute cases because these patients rarely need operation; all they need is an opening to relieve the pressure from the fluid and the gas. Cases frequently become chronic because the pressure is not relieved and sloughing occurs. Dr. Myles presented two small chisels that he has found most satisfactory and simple for opening the antrum.

Dr. George L. Richards said that it seems to him that the dental engine is an instrument that is destined to go out of use rather than to increase in popularity. It is difficult to work in the nose with the large wobbly, flexible shaft. He has used the straight instruments that Dr. Freer describes and the antrum with them can be opened. If an instrument will do the work, the simpler it is the better. Dr. Richards does not recommend the dental engine. Often the operation must be done away from electricity and where it would be difficult to carry a foot-power instrument. He recalled a case in which the patient was nervous and dreaded the coming of a second man who might have surgical propensities. In that case Dr. Richards was able to get into the sinus without the patient hardly knowing that anything but a nasal examination had been done. The instrument that he almost invariably uses for exploratory purposes is a medium sized beveled steel cannula which may be pushed in with the finger or in some cases may require a tap with the mallet. If the gas pressure be gotten rid of the patients often get well of themselves. However that may be, even in the very acute cases a puncture under the inferior turbinate and washing out with some simple antiseptic solution will lessen the severity of the attack. The curved instruments of course go in more easily than the straight ones. Dr. Richards had some difficulty in maintaining the opening, but with the instruments which Dr. Myles has shown he does not anticipate any trouble in the future. With the beveled instruments one does not get out sufficient tissue. Even in the acute cases it may bother the operator to introduce the cannula. In such cases, Dr. Richards simply reintroduces his bevel edge cannula. Opening in the middle meatus, he said, is easier than the puncture under the inferior turbinate. In most instances he has preferred making the opening in the inferior meatus. If the point of opening be selected with reference to the conformity of the face, the operator will find it somewhere between the first and second thirds of the inferior turbinate, carrying the instrument as high up as possible, he will go through a very thin wall. Sometimes it is necessary to go as far back as the second third. It must be remembered that at times there may be great variations. An idea of the anatomic construction of the antrum can be obtained by noticing how the teeth grow and by taking note of the palatal arch. Now and then there is an almost complete septa between the antra so that one cavity might be entered and not the other. Dentists must be instructed concerning the nasal side of these cases, and they can instruct physicians as to the dental side. It does not seem to Dr. Richards that the dental route is the better. The patients who may be treated through the alveolar process may be treated better through the nose. An opening through the mouth is abnormal and the alveolar opening always tends to close. The patients treated through the mouth continue coming to the clinic for a long time. He does not think many American patients would care for such an operation. In his district most patients would prefer to have a little purulent discharge through the nose, rather than to have a so-called radical operation. In reply to a question, Dr. Richards stated that the radical internal method is not indicated in cases in which there is mucoid or polypoid degeneration, though it may give a certain amount of preliminary information. As a diagnostic measure the opening can be made through the nose. In acute cases, recovery usually follows the relief of pressure. In cases complicated with empyemata of the ethmoidal cells or of the frontal or of some of the other sinuses, he would make the opening under the inferior turbinate. If the patient seemed to have insufficient drainage, he would enlarge the opening. If the inferior turbinate lies in such a way that it folds right over the antral wall so that sufficient room cannot be obtained, part of it may be taken off. Again, the front end of the inferior turbinate can be taken off. The cases must be individualized. In a case with comparatively smooth walls and comparatively uncomplicated, drainage and washing will usually suffice. It does not matter so much how long these cases have lasted; more depends on the character of the pus and the condition of the mucous membrane. In cases with polypoid masses, it is better to operate through the canine fossa, unless the instruments presented by Dr. Myles will enable the operator to get sufficient drainage in these cases.

Dr. Otto T. Freer, Chicago, said that he thinks that Dr. Richards has been a little unjust to the dental engine. The handpiece may be disinfected and he should not like to give up the use of so valuable an instrument merely because it can not be cleaned like the implements used for a laparotomy. Dr. Freer certainly has never seen sepsis follow his frequent use of the nasal burrs and trephines. The long burr cuts away the strong ridge left at the bottom between the nasal floor and floor of the antrum, after resection of the upper part of the nasal wall of the maxillary sinus, in a way no other implement can, so that the nasal floor shelves down into the antrum and drainage becomes as nearly perfect as possible. The trephine also perforates the nasal wall with great speed in several places and causes practically no pain. After the trephine the burr may be used to enlarge the opening.

METHEMOGLOBIN AS A FACTOR OF CONSERVATIVE METABOLISM.*

BERNARD OETTINGER, M.D.
Neurologist to the Hospital for the City and County of Denver.
DENVER, COLO.

DEFINITIONS.

Hemoglobin (Hb) is a crystallizable body which constitutes the largest portion of the colored corpuscle. It is a respiratory pigment, has the power to attract oxygen and also other gases. (Kirk.)

Hemoglobinemia is a condition in which the hemoglobin is dissolved out of the red corpuscle and is held in solution in the serum. (Gould.)

Oxyhemoglobin (O_2Hb) results when hemoglobin is united molecule for molecule with oxygen. It is the characteristic constituent of the red corpuscle to which the scarlet color of arterial blood is due. (Gould.)

Reduced hemoglobin is the result of deoxidation of oxyhemoglobin. (Gould.)

Methemoglobin (Met Hb) is a modified form of hemoglobin. It is the product either of incomplete decomposition of hemoglobin or of its excessive oxidation. The oxygen is more firmly combined in it than in oxyhemoglobin. (Gould.)

Methemoglobinemia is the presence of free methemoglobin in the blood. (Gould.)[1]

To the physician of to-day, methemoglobin, because it is known to be a more stable oxygen compound than oxyhemoglobin and is capable of reduction by the tissues only in slight degree, is universally regarded as a blood change deleterious to the organism, or, otherwise to express the equivalent, methemoglobinemia is always an intoxication, be it great or little in degree. It is amply proved that if methemoglobin be present in the blood in sufficient amount death results. Nevertheless, I differ from accepted opinion in so far as to say that methemoglobinemia must not be regarded as invariably deleterious to conservative metabolism, and that, in fact, therapy empirically makes use of this blood change to aid in conservation of nutrition. The following is offered in support of this opinion:

The toxicologist, Selmi, used the word ptomain to describe certain alkaloidal bodies formed during the process of animal tissue putrefaction. Herein the name derived from the Greek word signifying cadaver was appropriate enough. Gautier applied the name leucomain, from the Greek term signifying white of egg, to basic substances preformed in the body tissues or which are products of living tissue metabolism. This distinction, it was found, could not stand. Because putrefaction and normal digestion are practically identical processes, we are not surprised that some of the basic substances originally obtained from putrefying animal matter can be isolated from living protoplasm, both animal and vegetable. More than this, enzymes or unorganized ferments and dilute mineral acids are capable, as well as bacteria, of producing ptomains when acting on the nuclein molecule. These facts enable us to draw conclusions from findings in reference to such basic substances without regard to the usual dual classification. Concerning this argument, however, so much may be said as to their differentiation. The interdependent relation, as based on chemic formulæ, of some of these basic substances (leucomains) to others of the same class and their final elimination products, has been identified with successive oxidation and cleavage processes, as, for instance, those of the best known purin group, form a continuous oxidation series with uric acid as the final product from which urea may be attained by cleavage. Much less is known of antecedent and also of oxidized elimination forms of representative ptomains, such as cholin, muscarin, putrescin, etc., although, as a general proposition, the sufficient oxidation of these basic substances is known to render them innocuous. For the same reason, the relation in general between oxidation of metabolic products and pathologic reduction of red cells hereinafter considered, is clearer as regards the leucomains than the ptomains, although a like need for the oxidation of the latter remains no less obvious.

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] This definition given because as complete as any attainable, nevertheless does not convey the entire meaning of the term methemoglobinemia as used in this article. In experimentation on animals it has been found that an induced blood change from oxyhemoglobin to methemoglobin, in most cases, if not always, takes place within an intact red cell, disintegration occurring later, and hence we obviously may have a methemoglobinemia before the methemoglobin becomes free and reaches the plasma.

As clinicians, we are interested in the connection which retention of these basic substances may have to disease—a factor often recognized, at least, in general terms. C. E. Simon[1] says "both classes of substances (i. e., ptomains and leucomains) are of especial interest to the physician, as their formation or undue accumulation in the body may give rise to serious disturbances." Vaughan and Novy[2] state "the leucomains have been credited by many as playing the chief rôle in autointoxication," and, again, "Wiener's observations on uric acid show that the purin body is not only a nuclein cleavage product, but that it may also be a synthetic one. Furthermore, he has shown that uric acid is not only being made, but is also being constantly destroyed within the body.[3] The process of formation and decomposition results in the normal minimum excretion of uric acid. If, however, the latter change be diminished or inhibited, the amount of uric acid becomes apparently increased and may lead to disease conditions, such as rheumatism. The same view may be extended to the purin bases and the relatively large elimination of these bodies in leukemia may be due not only to increased formation, but also to decreased destruction."

As regards specific blood observations, Prevost and Dumas have noted an accumulation of urea in the blood where it failed of elimination by the kidneys.[4] and, according to Gschleiden, an accumulation likewise occurs in fever. Salomon found uric acid in the blood in demonstrable amounts in cases of pneumonia and fever. von Jaksch obtained blood by cupping from 102 persons, of which only a few were in health, and tested it for uric acid. He detected no uric acid in the blood of the healthy, but found it in varying amounts in the blood of patients who, as a result of heart lesions, of pneumonia, nephritis or anemia, were suffering from dyspnea. The same investigator detected xanthin bases and uric acid in exudates and transudates and also the former in the blood in various pathologic conditions. According to von Limbeck,[5] xanthin bases (i. e., purin bases) have been found in the blood in various diseases by Sherer, Mosler, Salkowski and Salomon. von Jaksch interpreted the accumulation of uric acid in the blood in dyspneic conditions to mean that in these occurred greatly lessened oxidation processes. von Limbeck points out that the error of this conclusion is demonstrated by Kraus, who, by comparative analyses of respired gases in cases of severe anemia as against those of healthy persons. found the coefficient, $\frac{CO^2}{O}$, to be the same in both conditions. In accordance, also, are the observations by Chvostek, Bohland and Biernacki that in simple anemia the patient, instead of using less oxygen, employs rather more than in health. A reasonable conception concerning all blood conditions which have been cited would be the following one, viz., that as a pathologic effect in a great many morbid conditions increased disintegration of tissue cells results in the increased formation of leucomains, the chief known source of which are the nucleins of the nuclei and the proteids of cell protoplasm. Also, it being established that progressive oxidation and subsequent cleavage advances the leucomains to a product suitable for body elimination or one required for further metabolism, *dyspneic conditions (without regard to clinical entity but merely as one sign of intoxication), are always manifestation of an inadequate effort on the part of the organism sufficiently to oxidize these cell disintegration products.* Or, to express the idea from a different view-point, *there is in the blood in conditions which result in increased tissue metabolism an accumulation of basic products which are prepared for further use or for body elimination by oxidation and cleavage processes, and, therefore, the same products up to the point of their sufficient preparation act as powerful reducing agents or deoxidizers.*

To one who approaches the subject without prejudice, the literature of methemoglobinemia develops some unconvincing conclusions as well as patent contradictions. He must be impressed by the fact that substances so far removed from others classed with them in physiologic effect or manner of therapeutic use as are hydrocyanic acid, amyl nitrite, iodin, turpentine, pyridin, chloroform, ether, chlorate and permanganate of potash, phenacetin and other antipyretic coal-tar products, certain toadstool and snake poisons, etc., require differentiation in the consideration of a systemic effect, even though all of these possess a common property to produce in sufficient dose a certain toxemia. He notes the statement by one investigator that before certain substances can change oxyhemoglobin to methemoglobin the hemoglobin must be freed from the corpuscle by the latter's disintegration. Another observer is equally certain that even in these cases the change to methemoglobin is primary and that the solution of the red cell occurs subsequently. If, as in this case, the same substances, as, for instance, arsenuretted hydrogen, snake venoms, toadstool toxins, be set down by a third authority as producers of hemoglobinemia only, the suspicion is born that at the door of the met compound, perhaps, are laid some of the ill effects of poisons whose paramount action is rapid solution of the red cells. It is true that disintegration of the red cell does follow methemoglobin formation,[6] and it is not surprising, for the reason that this superoxidation[7] of the corpuscle is needless in health and hence always presents an extraordinary form of hemoglobin. Yet, a legitimate question may be raised whether or not some other agent, beside that which produces the met oxidation, may not sometimes complicate the latter effect—for instance, the albumin destroying property and, therefore, destructive effect, on the red cell of potassium in the oft quoted met toxemia of potassium chlorate—a result which was manifest in experiments on herbivorous animals (rabbits); or, again, the possibility that in severe methemoglobinemia, the tissues being deprived of enough easily reduced oxyhemoglobin and unable to utilize the methemoglobin, do now attack the reduced hemoglobin, which, as we know, still contains considerable oxygen, deoxidizing it and, in turn, its derivatives up to corpuscular dissolution.[8]

[2] Vaughan and Novy: Cellular Toxins, 1902.

[3] In this case, although successive oxidation is not followed by elimination, it nevertheless has played an equally important rôle in the antecedent metabolism.

[4] Baginsky holds that the amount of the purin base, xanthin normally present in the urine may be increased tenfold in acute nephritis.

[5] Limbeck, Rud. R. von., Grundriss einer Klinischen Path. des Blutes, 1896.

[6] The following are summaries of two detailed studies of fatal methemoglobinemia: Brandenburg's case, a woman 28 years old, who drank at night a solution of 525 grains of potassium chlorate in water was received at the clinic the following morning. The blood examination showed severe leucocytosis, poikilocytes, but these not numerous; also irregularly shaped large and small red cells. The blood was chocolate brown, and showed by spectroscopic examination, the bands of methemoglobin. The separated serum had a brownish tinge, contained methemoglobin, as did also the urine. Counts of red cells from the first to the seventh day demonstrated a daily decrease in red corpuscles as follows: 4.3 mill., 2.5 mill., 2.3 mill, 2.1 mill., 1.9 mill., 1.6 mill. After the fifth day no methemoglobin could be found in the serum. Necropsy following on the seventh day, exhibited parenchymatous inflammation of the myocardium, the liver, stomach mucous membrane and kidneys, the last also showing intense hemoglobin infarcts. *(Grawitz.)*

K. Ehrlich and Lindenthal's Case.—Ten hours after initial symptoms of poisoning by nitrobenzol, the blood was chocolate colored, the serum brownish. the spectral analysis showed presence of methemoglobin, which disappeared on the eighth day. Red cells were rapidly reduced, 2,275,000 on the fifth day, and falling to 900,000 before death on the nineteenth day. Poikilocytosis appeared on the third day and soon reached a remarkable degree. Polychromatic and fragmented cells were abundant. Nucleated red cells were first seen on the third day, and thereafter in very large numbers of all sizes. On the ninth day, the leucocytosis previously low, rose suddenly to 61,000, and the nucleated cells reported at 24,700. The Hb fell steadily to 40 per cent., which, with 900,000 cells was a remarkably high Hb index. There were many myelocytes among the white cells, so that at one time the blood presented the appearance of leukemia. (Ewing.)

Mohr observed six cases of benzol poisoning among workers in benzol factories. In all there was methemoglobinemia, schistocytosis and hemoglobinic degeneration, while nucleated red cells, microcytes and macrocytes were numerous. (Ewing.)

Experimental research as to methemoglobin poisoning has been largely confined to the effects of potassium chlorate, because of the overwhelming blood change which follows the ingestion of large doses of this drug and the former comparative frequency of methemoglobinemia from this cause on account of common administration of toxic doses. A brief review of such research as given in von Limbeck's work on clinical pathology of the blood is as follows:

Marchand, who first experimentally studied the toxic effect on dogs of chlorin salts, stated that the absorption of the latter resulted in a methemoglobinemia which was the cause of death in acute toxemia. Against this conclusion, Stokvis took the position, from experiments chiefly on rabbits, that death in chlorate poisoning was solely due to salt effect and that the formation of MetHb was a postmortem change. This view was apparently refuted by Lenhartz and Riess, who demonstrated methemoglobin in intravascular blood of the animal experimented on. Following these experiments, von Limbeck was able to show by volumetric computation of 0 in the blood of dogs poisoned by $NaClO_3$ that in the latter, and possibly also in man, death in acute chlorate poisoning is due to asphyxia, resulting from lack of reducible hemoglobin. How great, says this observer, is the toxic effect of the chlorate salt as such on the organism, remains an open question which, while it can not be eliminated, may be answered in so far that for dogs and in acute poisoning, this effect is probably subsidiary to asphyxia as a cause of death. For herbivera this conclusion does not hold good. Stokvis, Marchand and Bokai showed that, with rabbits, death followed acute chlorate poisoning in almost all cases without the characteristic blood change and that at least a period of one and a half hours after death needed to elapse before methemoglobin could be demonstrated in the blood. Here the cause of death could be ascribed to the effects of chlorate salts as such. There was no disintegration of corpuscles nor did this seem to occur in acute poisoning of dogs. According to von Limbeck, in subacute methemoglobin poisoning, one must reckon with a greater number of complicating conditions which include production of methemoglobin, effect of salt as such on the tissues, decomposition of blood corpuscles, circulatory disturbances due to thrombi and, as the factor of chief importance, kidney irritation.

As subacute toxemia is the only form that would have to do with this argument, we are especially interested in its several dangers—certainly each as a toxic effect is sufficiently evil. And yet, aside from mere production [illegible] which needs a 66.6 per cent. blood [illegible] if the physician as he prescribes, could not depend on his judgment to guard his patient from grave tissue change arising from injudicious treatment as regards dosage and period of drug administration, said treatment causing, for instance, great cellular disintegration of the kidney, the liver or other excreting organs, he would need to take from his drug armamentarium many important constituents of it, such as chloral, phosphorus and its compounds, bromin salts, the coal-tar antipyretics, salicylic acid and its derivatives, etc. Hence, if it then be a matter for the physician, not that he must ever avoid a methemoglobinemia as such, but that in therapeutic use of substances capable of producing this blood change, he must avoid a toxemia in his patient, we find herein quite the same problem to solve in relation to these drugs as confronts us in the use of most others we employ in treatment. And, in the same case, the practitioner must be accorded the right to produce a methemoglobinemia of non-toxic proportions if he can be [illegible].[9] I believe the patient may be, and indeed is, often benefitted by an induced methemoglobinemia effected by drugs now empirically employed, *by oxidizing through this means the suboxidized leucomains which we have found in time of disease, accumulate in abnormal amounts in the blood. These powerful reducing agents are able to take 0 from methemoglobin, although the tissues can not.*[10] In the asphyxia of extensive and, therefore, toxic methemoglobinemia pulmonary respiration is, to a great [illegible] because the hemoglobin, unreduced by the tissues, is brought to the lungs already oxygen laden. Herein methemoglobin acts as no special poison, for oxyhemoglobin returned to the lungs would give them as little to do. On the other hand, the partial asphyxia of disease, as evidenced by dyspnea and cyanosis, has as one, if not exclusive cause, *the increased amount of oxygen required by the system to oxidize the tissues plus the leucomains or other like basic reducing substances, with which need the lungs can not keep pace.*

With an induced methemoglobinemia in just that degree that may be required to sufficiently oxidize the basic substances, thereby preparing them for elimination or for further use in the animal economy, we obtain two paramount results: (1) The O_2Hb is conserved for use of the tissues. In reference to this statement, it is true that methemoglobin contains the same number of oxygen atoms as oxyhemoglobin, which point might be advanced as an argument that the leucomains could as well be oxidized by the normal oxy-compound as the met-compound. It must be remembered, however, that the oxygen of the latter is in a different form wherein the oxygen atoms are more closely bound within the molecule than in oxyhemoglobin, and therefore the met molecule requires in all probability a greater amount of suboxidized basic material for its reduction than would be needed for the loosely bound normal oxy-compound.[11]

---

[7] "In apparent contradiction to the fact that bacteria are capable of converting MetHb. to Hb. is that demonstrated by J. F. Lipowski that by means of pure cultures of other bacteria O_2Hb can be changed to MetHb. In the first case we have to do with reducing, in the second with oxidizing and oxygen-forming microbes." (Rudolf Kobert.)

[8] If Co_2 be passed through a solution of oxyhemoglobin for a considerable time, reduced Hb is first formed, but if the process be prolonged, the Hb is decomposed, a precipitate of globulin is thrown down and an absorption band similar to that obtained when Hb is decomposed with acids (acid hematin) is observed. (Landois and Sterling.)

[9] But for a generation of prejudice, originating in the therapeutic abuse of potassium chlorate and which pronounces all methemoglobinemia essentially toxic, a conclusion so self-evident would scarcely need discussion, if we but remember our daily use of three of the MetHb producing halogens in the form of iodin, chlorin and bromin compounds or salts, also the coal-tar analgesics and antipyretics. That one is called on to exercise care as to dose and period of administration of this class of drugs so as to avoid pushing a methemoglobinemia beyond therapeutic limits or because *of* other possible deleterious effects there is no question.

[10] "It (methemoglobin) is, however, affected by the products formed in the blood during asphyxia, while COHb is not, the MetHb formed by the nitrites is reduced by these products to Hb, which as it passes through the lungs takes up O." (Landois and Sterling, Human Physiology, Fourth Edition, 1892.)

(2) *Some oxyhemoglobin is produced within the tissues, and herein vicarious function for an embarrassed pulmonary respiration is established.* The view that oxyhemoglobin may be furnished the organism otherwise than by the lungs may appear radical, yet apparently forces acceptance in the light of the following observations, viz., that if a careful decomposition of methemoglobin be made in glass by just enough of the reducing agent to permit the process to proceed slowly, spectroscopic examination will demonstrate the presence of oxyhemoglobin absorption lines before those of reduced hemoglobin are attained, the sequence, therefore, being methemoglobin, oxyhemoglobin, reduced hemoglobin (Jaderholm). Not only this, but the reverse is also true. If reduced hemoglobin be slowly oxidized to methemoglobin in glass, the spectroscope shows that here, too, oxyhemoglobin is an intermediate compound, the sequence being reduced hemoglobin, oxyhemoglobin, methemoglobin (Saarbruch). The similarity of chemical reaction that attends methemoglobin formation and its reduction in the experimental animal to the same procedure without the body permits us to believe that where either of the preceding reactions occur during life oxyhemoglobin must also appear as an intermediate product. *Hence, in induced, slight methemoglobinemia some of the methemoglobin reduced to oxyhemoglobin by leucomains is, no doubt, further reduced by the tissues themselves, or, again, in the course of an induced oxidation from reduced hemoglobin to methemoglobin not all of the intermediate oxyhemoglobin would attain the methemoglobin state, because of the appropriation here also of some of the former by the tissues.* This conception of methemoglobin utilization in disease, it will be noted, differs materially from earlier theory that the internal administration of potassium chlorate benefits by furnishing oxygen to the tissues in the course of its decomposition. The present hypothesis includes a series of reactions, (1) superoxidation of reduced hemoglobin or oxyhemoglobin to methemoglobin; (2) reduction of methemoglobin to reduced hemoglobin, with concurrent oxidation of reducing substances in the blood; (3) the occurrence of oxyhemoglobin as an intermediate product in course of corpuscular oxidation and reduction.

But, it may be urged, if methemoglobinemia at any time be other than harmful, how comes it to be associated with various pathologic conditions and in these without extraneous origin? It has been found in exudates and transudates, also in the blood following severe burns and scalds, in insolation, septic conditions, in Addison's disease, etc. The question may be answered thus: In these and probably many other morbid conditions, methemoglobinemia (always noted as only a trace and by no means of a degree that could be responsible for death of the patient) represents a conserving process of nature which we imitate by inducing therapeutically a like blood change. Nature accomplishes this by the products of metabolism. Of such products, which produce methemoglobinemia, two which may be cited are pyrocatechin and hydrochinon, and doubtless there are many others.

Viewed from the dual standpoint of oxidizer, both of reducing substances in the blood and of the tissues themselves when for some reason pulmonary respiration is inadequate to furnish sufficient oxygen, induced conservative methemoglobinemia would explain the present empiric use of substances which produce the met compound, viz., nitrite of amyl in angina pectoris, pyridin inhalations in asthmatic attacks, potassium chlorate in tonsillitis and its occasional use, long continued and with success to prevent recurrent abortions, the bromin salts in epilepsy, iron as the perchlorid in chorea minor and as insisted on by the older practitioners in sepsis, Lugols solution and the iodid of iron in scrofulous and cachectic conditions, potassium permanganate in anemia, quinic acid[12] recently recommended as specific treatment in gout, etc.

Because fumes of pyridin proved useful in asthmatic attacks, I concluded to try potassium chlorate as a constitutional in the same condition, and obtained good results, although I would not care to have a patient continue long on this drug, or at least without constant supervision, for fear of damage to the kidneys. Also, one need be clear as to one point. I do not mean to say that, because each of a number of drugs can produce a methemoglobinemia, they may be indifferently substituted in treatment, one for another. Without doubt other affinities, too, of these remedies must decide our choice. The rapid but evanescent relief from dyspnea and vasomotor spasm effected by use of amyl nitrite or pyridin fumes could not well take the place of the prolonged effect on metabolism of potassium chlorate or the latter of the bromin salts which experience has shown approaches specific effect in epilepsy. Yet substitution of met-producing drugs is, to some extent, efficient, as we have seen, and may again be noted herein that the one vegetable drug which it has been found fills a serviceable place beside the bromids in the treatment of epilepsy is *Solanum carolinense*, a plant which belongs to one of several classes that contain so-called saponin bodies, glucoside substances which produce methemoglobin.

There are many other facts pertinent to this line of thought which might be added, but enough has been said if, in response to this first paper, members of the profession, and especially such observers as are able concurrently to utilize clinic and laboratory, will find the subject of sufficient interest to test the principle here advanced, full confirmation of which would materially extend the province of rational therapeutics.

I take pleasure in expressing my obligation to Prof. W. E. Engle of the University of Denver for the privilege of working in his laboratory and for his assistance in examination of blood with the spectroscope.

Since writing the above article J. von Mehring's[13] frequently quoted thesis on potassium chlorate has come into my hands. One important conclusion of von Mehring was "that with an accumulation of CO_2 in the blood (blood from carotid artery in dyspnea) and in an amount not resulting in death, the deleterious effects of $KClO_3$ are increased in great degree" (i. e., absorption bands of methemoglobin were noted after a much shorter space of time than with normal blood from the carotid). The same result was observed after addition of small amounts of acid sodium phosphate to blood.

---

[11] In reference to this, the fact already pointed out, that methemoglobinization of the red cell is equivalent to a superoxidation, is again of interest here, in that it suggests the possibility that the O atoms when freed act as nascent O. According to Engler's views, the first step in systemic oxidation is the decomposition of peroxids by that class of ferments, known as peroxydases, while, according to Landois and Sterling, it is the active or nascent O that acts as so powerful an oxidizing agent that it converts water into hydric peroxid, N of the air into nitrous and nitric acid and CO into CO_2, which ozone does not.

[12] Dry distillation of quinic acid yields pyrocatechin and hydrochinon (U. S. Dispensatory 17 Ed., page 1432) both of which transform O_2Hb to MetHb.

[13] Mehring, J. von: Das Chlorsaure Kali, 1885.

My own conclusions are just contrary to the above where slight, therapeutic methemoglobinemia is concerned, and which may, therefore, be stated thus—in dyspneic conditions, the greater the rapidity of an induced methemoglobinemia proportionate to the needed oxidation of increased amounts of reducing substances in the blood, the greater and more rapid the benefit to the patient. This is also in accord with personal clinical experience as regards relief of dyspnea by administration of certain methemoglobin-producing drugs in small amounts. I have not tested the effect of this same class of drugs in phosphorus poisoning, but I find in von Mehring's thesis the following reference: "Tessliers[14] observed at the clinic of du Moulin in Ghent a case of phosphorus poisoning, wherein the patient, owing to great repugnance to turpentine, was given potassium chlorate, with apparent beneficial results." It is significant that turpentine shares with potassium chlorate methemoglobin producing properties.[15]

SYMPTOMS, DIAGNOSIS AND PROGNOSIS OF UNCOMPLICATED INTESTINAL AMEBIASIS IN THE TROPICS.

W. E. MUSGRAVE, M.D.
Pathologist, Government Laboratory; Physician in Chief, St. Paul's Hospital.
MANILA, P. I.

SYMPTOMATOLOGY.

The symptomatology of amebiasis varies more than is generally taught and it seems desirable that this more comprehensive clinical picture be taken up more in detail, calling particular attention to the early diagnosis of the disease and to some of the peculiarities of the milder forms.

In discussing this question, writers have generally divided the cases into groups according to the clinical manifestation which, as clinical conveniences, answer the purpose and are fairly uniform. Osler considers it under the headings acute and chronic. Harris divided the disease into very mild forms, moderately severe cases and very severe ones. Lafleur and Futcher divide them into grave and gangrenous forms; those of moderate intensity and chronic ones.

I shall discuss the subject under the following convenient clinical divisions:

1. Latent and masked infections.
2. Mild and moderately severe ones.
3. Severe cases, including gangrenous and diphtheritic ones.
4. Infection in children and in the aged.

These clinical forms often change from one to the other and may do so several times during the course of the disease in the same patient. The amebic process in all is essentially chronic, but acute symptoms from concurrent or secondary infection by other agents are frequently seen.

Latent Infections.—By this term are designated those cases in which there is a true pathologic process, containing amebas without diarrhea or other symptoms which would ordinarily indicate the presence of such an infection.[1]

It might be objected that this latency is really a period of incubation. In a sense, this may be true, but as many of the cases, even fatal ones, always remain in this class, and as there are nearly always certain manifestations in addition to the positive one of the presence of amebas, it seems better to give latency a separate place in the clinical classification; and, furthermore, the most useful results will be secured by making such divisions rather sharp and by confining the incubation period in all classes of the disease to the unknown time between the infection and the appearance of amebas in the stools.

Under these circumstances it is readily seen how difficult latency may be to differentiate from what properly may be termed incubation. This becomes all the more difficult when we remember that amebas may possibly be found transiently in the normal intestine and that there are at present no practical means of differentiating between species of amebas. It is clear, therefore, that by basing treatment on the method of diagnosis recommended, unnecessary therapeutics may occasionally be instituted.

Cases of this latent class are not infrequent in Manila and are becoming more and more recognized, as we learn more of the character of the infection, and I do not believe that giving them a place in a purely clinical classification can be criticized by those who have had experience with the disease in the tropics. They are certainly of very great importance and deserve the most careful consideration, for the life of the patient often depends as much on the diagnosis and treatment here as it does in some of those clinically more active infections. Some of these patients, as has been noted, never show clinical manifestations during life, and in some others, when such symptoms do develop, the time for successful therapeutics may have passed.

The course and outcome, as in some other types, varies greatly. Usually, after a period ranging from a few weeks to many months, more active symptoms develop and in general the patient assumes the clinical type of a more or less severe dysentery. This change may occur gradually or very suddenly, and in the latter instance, unless the patient has been under very close observation, we may be misled into believing it to be one of primary acute amebic dysentery. On the other hand, some of these cases go on to recovery or death, without ever showing active diarrhea.

The symptoms during latency may be entirely absent subjectively and objectively for considerable periods of time; but usually conditions develop, which, by the aid of postmortem findings, we have come to recognize as indicating the nature of the process. As has been stated in previous publications, these cases are essentially those in which the lesions are in the cecum and upper colon. Careful stool examinations, obtained after a hydrogogue cathartic, often show mucus mixed with old discolored blood and other tissue elements, indicating both the location, and with their associated amebas, the nature of the infection. Rather indefinite, dull, aching abdominal pains are frequent and are often attributed by the patient to "taking cold," because they are first noticed during the night or early in the morning, and afterward are usually most active at these times. There may also be some "indigestion," lassitude, headache, a coated tongue, foul breath, etc. Loss of appetite may be present, and the patient often notices slight loss of weight, and, if a woman, usually complains of loss of color and a yellow skin. Physical examinations will usually secure additional data. Deep palpation discloses tenderness along the colon, most often over the cecum, and if the duration is great and the patient not too fat, a thickened intestine may be made out.

NOTE.—The other papers in this symposium will appear in a later issue of THE JOURNAL.

[1] Dock, in 1891, reported extensive amebic ulceration in the cecum of a man who had not had dysentery and who had passed only normal stools. Councilman and Lafleur, in 1892, and Lafleur, in 1897, called attention to the fact that an amebic process may be latent, the stools being well formed and no amebas being found in the small adherent flakes of mucus, and that in these cases the true nature of the disease is often not suspected until abscess of the liver calls attention to it. These observations have been confirmed by Osler, Rogers and many other writers.

Examples of this class of cases, as stated above, have been reported by several writers, and I have called particular attention to them in previous publications. Two additional examples from many that might be given are briefly as follows:

CASE 1.—A young married woman, previously in good health, came to the Philippines in 1903. About three months later she consulted me, complaining of general lassitude, dull pains in the back of the head and neck, coated tongue and bad breath.

Treatment.—She was given calomel and soda in broken doses, followed by a Seidlitz power the following morning, when examination of the stool showed amebas fairly numerous and of good size. She was placed on a bitter tonic of iron, quinin and strychnin. For the next three months there was little change in the general health and the bowels continued regular. Amebas were again demonstrated in the stools and this time were mixed with mucus, showing streaks of old discolored blood.

Course of Disease.—During the next month she complained of dull abdominal soreness, which on pressure was more marked in the region of the cecum. "Indigestion" was complained of, anemia was noticeable, and she had lost five pounds in weight; but the bowels were still regular and apparently normal. At this time she consented to take enemas, but after about a week's time she became dissatisfied and passed to the care of another physician, on whose recommendation she spent three months in Japan. While in that country her symptoms of indigestion were less noticeable and headaches were absent, and she returned feeling in better health and spirits. Shortly after her return to Manila, however, there was a recurrence of the symptoms before complained of, and in a more pronounced form; in addition flatulence became annoying: but there was still no diarrhea. Stool examinations after a hydragogue cathartic showed numerous amebas, and considerable mucus with some blood. Her symptoms, as usual, were relieved temporarily by the cathartic. About this time she had had a moderate diarrhea, which lasted for a few days and was followed by constipation, with severe pains in the right iliac region. Another attack of diarrhea came within a week and dysenteric feces began to be voided. Typical acute dysentery developed, and death occurred within ten days after the acute onset and nearly one year from the time when amebas were first found in her stools.

Autopsy.—At necropsy an old advanced amebic infection of the cecum and upper colon, with most extensive ulceration and chronic fibrinous adhesions were found. More recent amebic lesions were scattered throughout the rest of the colon, and an exquisite acute diphtheritic dysentery was engrafted on the older process.

CASE 2.—A Filipino prisoner in Bilibid prison showed amebas in his stools on repeated examinations for more than four months. Sometimes after administration of salts blood cells were present, and the mucus was sometimes stained with dark, partly decomposed blood. He was apparently a perfectly healthy man, and had no diarrhea or dysentery.

Autopsy.—At necropsy, following death from intercurrent lobar pneumonia, the cecum, and ascending and transverse colon showed amebic ulceration, which was quite advanced about the hepatic flexure.

In addition to latency, the symptoms of this infection may be completely masked, and mistakes in diagnosis are, no doubt, frequent when the disease is endemic.

The clinical manifestations of several diseases may mask those of a latent or mild amebic infection. The scope of this paper will not allow a full discussion of these, and the subject will be treated more thoroughly in a paper soon to appear on the complications and sequelæ of amebic infections. Perhaps the most frequent of these conditions, and those which are also likely to lead to mistakes, are chronic constipation and gastritis or appendicitis. The latter of these has already been discussed.[2] Gastric symptoms of more or less severity are particularly prevalent in the tropics, both with and without amebic infections of the colon; and for this reason, particularly when severe, often completely obscure the less active disease when present.[3]

Numerous examples might be cited, showing the variety and prevalence of such conditions; but my object here is to call particular attention to it, without leaving the impression that every case of stomach trouble in the tropics masks an amebic infection of the colon.

Constipation is a very prevalent condition in the tropics, as it is in the United States, particularly among women; and, as might be inferred, may frequently mask amebic infection in the early stages, and in the latent and less active forms until irreparable damage may have been done to the colon.

I have under my care now a woman who has for years been a chronic sufferer from constipation. About five months ago she began to lose weight and other symptoms developed, suggesting probable amebiasis, which was confirmed by microscopic examination of the feces. During this time, the constipation had persisted, notwithstanding that blood and mucus were obtained with every specimen secured by salts, and diarrhea did not develop until about two weeks ago. Dysenteric stools quickly followed, and treatment, which is still being given, was instituted.

Such cases as this and th[illegible]cribed are of frequent occurrence in [illegible] and support the conclusion which I have already expressed, namely, that the presence of amebas in the stools should always be considered diagnostic, at least in so far as treatment is concerned. The fact that one occasionally sees a case similar to those mentioned above, in which clinical dysentery never appears, the patient never feels ill, and amebas eventually permanently disappear from the stools, is not a sufficiently strong argument against the conclusion given, until such time as definite data indicating the final outcome are available early in the infection.

---

[2] Bull. 18, Bureau of Governnment Laboratories. THE JOURNAL A. M. A., April 8, 1905, p. 1098.

[3] I now have in mind such a case in a very prominent man in Manila. He had for years been a sufferer from chronic gastritis, and after a few months' residence in the Philippine Islands the symptoms became more aggravated, and just as previously, he had periodic outbreaks of diarrhea, only that with the increase in the stomach symptoms, the diarrhea became much worse. At the end of six months he was confined to his bed, unable to retain food, and reduced almost to a skeleton, and the bowel evacuations had become dysenteric. An examination of the feces showed numerous amebas with blood and mucus. Under careful treatment, directed particularly to the amebic infection, he slowly improved and was eventually restored to his usual health.

Mild and Moderately Severe Cases.—These form by far the great majority of those seen in Manila at the present time. Formerly they occupied about the same place as that occupied now by latent ones, i. e., they were treated as simple diarrheas from other causes, and often the true nature of the infection was not recognized until the development of bloody mucus discharges, or more often the pathologic report called attention to it.

The symptomatology of this class of cases, as well as that of the more severe cases, is so well understood and has been so often described that I will condense that part of the paper into calling particular attention to the conclusion which we have come to in our work in Manila, that diphtheritis and other acute pathologic processes seen at postmortem in this disease are the result of other etiologic agents and are not a part of the true amebic infection.

The larger number of these cases develop from the latent ones already described, just as the majority of the more severe ones usually arise from this type. It is impossible to say just what proportion of them develop as such primarily or follow a more or less definite latent period; clinically, the time of onset is usually dated from the appearance of diarrhea. There may be prodromal manifestations before the onset of diarrhea or dysentery in cases in which amebas may not be found at the time, but here the prodromes are very like the manifestations of the latent type, viz., indefinite abdominal pain, generally attributed by the patient to "taking cold" and explained by not a few as being caused by sleeping without an abdominal band on certain cool nights; tenderness on palpation along a part or all of the colon, "indigestion," headaches, usually of a dull cerebral type, a general feeling of depression, ill health and irritability of temper, and sometimes melancholic tendencies, with anemia and loss of weight.

In the majority of properly treated patients the disease clinically rarely passes from diarrhea, but sometimes here as well as in the larger number of untreated ones diarrhea is only preliminary to a more violent clinical picture. Many cases, however, even without treatment never become dysenteric in the general acceptation of the term.

The course in uncomplicated cases is extremely chronic and the outcome rarely recovery, being most commonly the development of "sprue" or chronic gastroenteritis giving other clinical pictures; and the most frequent termination is death from intercurrent disease or complications. I am still in correspondence with a number of old Manila patients, now in the United States, in which the cases are of from four to six or more years' duration, and in which symptoms are still very much the same as when the patients left Manila.

Following a gradual onset from a period of known latency, the diarrhea is usually intermittent and more marked in the mornings, consisting of two, three or four soft, semi-fluid stools, without mucus or blood and passed without pain. This condition may last from one to several days, and is usually followed by a tendency to constipation. Succeeding outbreaks usually become more severe and may last for days, weeks or months, until the appearance of blood or mucus causes the patient to realize that he has dysentery, and it is at this stage that he most often appears for treatment. When the onset is more sudden, some blood and mucus are frequently noticed in the stools from the first; there may be some tenesmus and symptoms may continue for a few days, to be followed, as in the first case, by a period of constipation. The subsequent course of the disease in the two cases may not be different, but usually the more acute the onset the more rapid development of more severe symptoms. It is certain that in not a few of these the sudden outbreak is not due to amebas, but to other causes. There are frequently the same extrinsic causes for these outbreaks as when they occur in subjects free from amebas, which is, of course, of frequent occurrence in the tropics, and, in addition to this, careful inquiry will often reveal that there were significant manifestations before the onset in the amebic cases, and it may even be observed when amebas were known to be present for some time prior to the outbreak.

Severe Cases.—The clinical aspects of this type of the disease are the best understood and carefully described. and need but a brief summary here. As is true of the class of cases just discussed, in by far the greater number of cases it develops from a previously existing latent or milder type.

To this class belong also the diphtheritic and gangrenous cases, which are always severe and are undoubtedly due to a concomitant or secondary infection with some other agent, which is also the cause of severe forms of other types.

The onset here, whether occurring in an apparently healthy subject or following an existing milder type, is usually quite sudden and is characterized by the phenomenon of an acute dysentery from other causes. There are frequent mucus bloody passages, with tenesmus, colic, thirst and perhaps some fever.

In this severe form, whether apparently primary or secondary to one of the milder types, the course is usually much shorter and death is frequent from toxemia, perforation of an ulcer or from exhaustion of the patient. There are cases in which postmortem examination may show excellent nutrition and a rotten intestine, with either extensive gangrene or diphtheritis. Even in these, however, not infrequently the severe symptoms subside under treatment, and the case may continue as a more moderate one, or may be even mild in its symptoms, thus exemplifying the previous statement that the clinical types designated may frequently change from one to another even in the same patient.

Infection in Children.—Particular attention has been called to the disease in children by several writers.[4]

I have had twenty-one cases in children between the ages of 6 months and 10 years in private practice in the Philippine Islands, and one necropsy in a girl 3½ years old. When we consider the increased danger of infection which is present for children in the tropics, we must conclude that they present an increased natural immunity, a fact which is still further borne out by a study of cases in which infection does occur, for the disease is usually of a very mild type and is very amenable to treatment. In only two of my cases (in addition to one death) was the disease what could be called moderately severe from its clinical manifestations. The symptoms, in general, conform to the milder types in adults, and recovery is almost certain under proper treatment. I have seen children in whom there was undoubted active infection recover without treatment.

---

[4] Amberg, in 1901, carefully reported five cases from the Johns Hopkins Hospital, and reviewed the literature on the subject. *Harris reported* thirty-five cases, four of them in children under 10 years of age. Strong found amebas in the tuberculous ulcers of a 3-year-old child; Slaughter in liver abscesses of a 17-year-old boy; Kartulis in children of all ages except infancy; *Pfeiffer* in the stools of several children; Lamb in a 2-year-old child; Lutz in the stools of a little girl; Sonsino in the intestinal mucus of a child; Cahen in a girl 4 years old; Gneftos in the liver abscess of a 6-year-old girl. Oddo (1897) reported twelve cases of liver abscess following dysentery in children between the ages of 2 and 13.

The aged, as in the case of children, seem to manifest a decided natural immunity; but, when once established, the disease in them is usually of more serious import than even in young adults. The symptoms are commonly of a severer nature, the course is more rapid, and the mortality higher, generally, as in other patients, due to complications or to intercurrent disease.

One thing particularly noticeable both in children and in the aged, as well as in natives of the Philippine Islands, is the great relative infrequency of liver abscess. I have not seen a case of liver abscess in more than one thousand clinical cases and one hundred autopsies of natives of the Philippine Islands.

Analysis of Symptoms.—All varieties of facial aspect are seen, from a healthy one in some of the rapidly fatal cases to the more emaciated, anemic, yellow and even cachectic of some in the old long-standing ones. Usually for a long time the patient does not appear to be ill, and I have seen patients with the disease of more than two years' duration who had lost no time from the daily occupation.

In the early part of the disease the skin rarely shows any noticeable change, but in the old emaciated cases there is a general waste and a scrawny, dull, goose-flesh skin, often of a muddy color or even jaundiced. In this class of cases there is frequently an odor which is quite disagreeable and which is as characteristic as for any of the diseases in which its diagnostic value is emphasized. Perspiration is usually not very active, but cases are occasionally seen in which the night sweats equal those of tuberculosis. Edema, particularly of the feet, ankles and less frequently at the hands, and the face about the eyes, is often present, but is not necessarily an indication of Bright's disease. Albuminuria and casts may be present at times when these edemas are noticed; and involvement of the kidneys is frequently observed postmortem, though in the majority of the cases terminating in recovery the proper functioning of the kidneys is restored, and there is no further trouble from this source. Bed sores are rarely seen, except in the most chronic types of old emaciated, anemic patients, shortly before death. Boils are frequent in the tropics during convalescence from any wasting disease, and in amebiasis they are not exceptional. Of rashes, urticaria is of quite frequent occurrence and often annoying in its persistence. Quinin rashes, from absorption of this drug, are the most frequent and troublesome, often requiring a suspension or change of treatment. Enlargement of the superficial lymphatics without pain is common, particularly among natives; but this is so frequent an occurrence in health and other diseases that diagnostic importance can not be attached to it.

Digestive System: The organs of digestion bear the brunt of this disease, and it is here that diagnostic symptoms are most frequently observed. The appetite is most generally good, particularly so in the latent and mild cases during the early part of the disease. Later catarrhal conditions of the upper intestine, stomach and even esophagus are followed by variations in the appetite, due to such alterations. In the early disease, likewise, but little or no discomfort is felt from satisfying a normal desire for food, but later such action is often followed by an increased diarrhea and by a further disturbance of the already disordered upper digestive tract.

The tongue is in no sense a valuable interpreter of the conditions at the seat of the amebic lesions. It may be clean or coated with furs of various colors and types. It may be large or swollen, showing the marks of the teeth along its edges, or it may be red and pointed. In very old chronic cases, in which the clinical picture is that of sprue, the tongue is one of the valuable indicators and here often shows small ulcers along its sides and under the tip. Glossitis, with superficial ulcers and hyperemia of the mucous membranes (sprue), is not uncommon, and when present causes a dryness and burning sensation, which is very annoying. In the same class of cases, too, the frequent lesions of the esophagus cause a burning pain along this viscus, which is aggravated by acids or solid food. Thirst is usually increased and often markedly so when the clinical symptoms are quite active, due, no doubt, to the loss of body fluids through the ulcerated bowel.

Symptoms referable to the stomach depend, for the most part, on various stages of catarrh of this organ and do not differ from symptoms of similar conditions due to other causes. In the early part of the disease, the stomach most frequently remains in good condition, but in the later stages, and sometimes quite early, its symptoms may be very annoying. Nausea is frequent, but vomiting rare at any stage. Both these conditions are aggravated and frequently are direct sequences to treatment by enemas. Symptoms of hyperacidity, with beefy-red tongue and epigastric pain, (heart-burn), are encountered from time to time in all classes of cases; but a fermentative condition, with gas, a large, coated, flabby tongue, nausea and loss of appetite, are more common conditions.

The small intestine may be normal, but sometimes in the more chronic cases it shows a general catarrhal condition, which manifests itself by the usual symptoms of enteritis of other etiology. True amebic ulceration occasionally extends for from 2 to 10 cm. into the ileum, and in one case a perforation of an ulcer above the valve occurred, and the symptoms brought about by it closely resembled those seen in severe infection of the cecum.

The Large Intestine and Feces: The bloody-flux interpretation of the word dysentery must be abandoned in this disease, or, perhaps, a better solution would be to change our nomenclature so as to avoid calling it dysentery at all. It is true that diarrheic, or even dysenteric, stools are present at some time during the course of the disease in the *majority* of cases which proceed to a fatal termination; but even here this is not always so, and true dysenteric stools are not the rule in patients in whom treatment has been instituted early and properly administered.

There are numerous examples in literature of patients who have died of the disease in whom during life there was slight or no clinical dysentery. Such cases have been reported by Councilman and Lafleur, Osler, Dock, Strong and Musgrave and many others; and we (Mr. Clegg) have emphasized it in a recent paper.

In this paper I have already cited cases, and to them could be added at the present time a considerable number in which there was no diarrhea or dysentery at any period during the course of the disease, and yet death occurred from perforation of an ulcer or from intercurrent disease. Further, within the past year, in addition to a case already mentioned, I have performed the necropsy on the body of a patient who had been treated for more than six months for constipation, in whom advanced amebic ulceration of the cecum and ascending colon was found after death, resulting from perforation of a liver abscess. Such cases, of course, are not the rule, but they are sufficiently numerous to be of importance and are emphasized particularly for the purpose of demonstrating that, as in the case of many other infections, experience broadens our conception of the clinical picture.

With this data, I am prepared to state that in this disease there may be any stage between constipation and severe clinical dysentery, or alternations between these two conditions may be present throughout the course of the disease; and it is in this variation that we secure data for the arbitrary clinical division of the cases.

From what has been said it is seen that this clinical division is not necessarily borne out by the pathologic picture, and, therefore, it must not be inferred that the disease is of necessity mild because of the absence of a severe diarrhea.

In the great majority of cases, after a more or less prolonged incubation or period of latency, alternating periods of diarrhea and constipation develop, and usually the diarrhea becomes more severe with each return and persists longer, the constipation becoming less marked until finally formed feces are no longer passed. The diarrhea is usually more pronounced in the morning and after meals. In long-standing cases, the patient *complains that the food passes through unchanged as* soon as eaten.

There is nothing characteristic in the macroscopic appearance of the feces. Their consistency, amount, color, etc., may vary between the widest limits. In the early stage of the disease they are frequently formed and otherwise normal, and the surface may or may not show coatings of mucus sometimes streaked with blood. The morning specimens are usually the first to have a diarrheic appearance and are often copious and fermenting. When the infection is more advanced, the feces may take on the appearance of those due to chronic catarrh—fluid, with mucus and particles of undigested food. On the other hand, frequent large, light gray fluid or granular, foul-smelling evacuations, with mucus, and with or without fresh or old blood, and sometimes masses of tissue and occasionally casts of the mucosa, may persist for weeks or months. Again, particularly when the infection is low in the colon and rectum and there is some severe secondary infection, the stools may resemble those of acute dysentery in character and symptoms produced. The odor of the feces in many cases is particularly offensive and all but characteristic, so much so that diagnostic importance may be attached to it. The next most important point of diagnostic value obtained from a macroscopic examination is the indication of the location of the infection by the character of the blood, when such is present.

Amebic infections can be diagnosed with certainty only by microscopic examination of the feces or other material, and by this method also other valuable data may be obtained.

The best method of securing a specimen and the manner of procedure for microscopic examination have been described in *Bulletin* No. 18, Bureau of Government Laboratories, and some additional points are mentioned under the heading of diagnosis in this paper.

The presence of motile amebas should be considered diagnostic, at least in the tropics. The difference in size and numbers, the presence or absence of enclosed blood cells, and other described points of differentiation, I believe to be fallacious, as pointed out in a previous publication.

Many other parasites and substances of more or less importance are often found associated with amebas. Among animal parasites are the *Trichomonidæ, Cercomonidæ, Megastoma entericum, Embryo strongyloides,* ova of uncinaria, *Trichuris, Tænia, Oxyuris,* and others, either singly or in various combinations. At least some of these have a part in the production of the symptoms and must be reckoned with in treatment. Of other substances present may be mentioned leucocytes, red blood cells, pus, epithelial and other cellular elements. Various crystals are often present, but with one or two exceptions are of no diagnostic importance. Many other substances may be found, but as they have been so repeatedly discussed by others and are of such slight importance to the subject in hand they will be omitted.

Circulatory System: The circulatory system in this disease shows essentially the changes of secondary anemia. The pulse is usually of good quality, except in the later stages or in the presence of complications, when it takes on a type due to such involvements. Early in this disease the blood shows little or no change, the red cells being normal in numbers and free from abnormal elements, the leucocyte count is normal, the relative proportion of the cells is not disturbed, and the hemoglobin estimate is also normal. As an uncomplicated case progresses, the red cells begin to show changes due to anemia, and in the later stages the irregularity in their size and shape may be quite marked, and the count may show great reduction, notwithstanding the loss of fluid from diarrhea. The leucocytes under like conditions show some disturbances in relation of varieties, usually an increase in polynuclears and eosinophiles, but these changes are never such as to be of diagnostic value. Hemoglobin decreases with a reduction in the number of red blood cells. The spleen is not enlarged, except in some severe cases complicated by or associated with other infections.

Temperature: Fever is most often absent throughout the course of the uncomplicated disease. It may be present in a moderate degree, when it is usually of an intermittent type, highest in the afternoons. In acute exacerbations from any cause, and when there is an intense secondary involvement, particularly diphtheritis, it may be an important factor. Only recently I was for some weeks very much puzzled by an intermittent temperature, reaching its maximum of from 38 to 39° C. about 10 o'clock a. m. daily, in an amebic patient, until other symptoms proved the presence of an intercurrent syphilis. It is frequently found, but by no means constantly so, in liver abscesses. Here, if the abscess is also the seat of bacteria in considerable numbers, the septic temperature may closely resemble that of a malarial infection, endocarditis or almost anything else, of either the intermittent or the remittent type. On the other hand, one occasionally finds a large liver abscess without fever at any time. As the disease becomes more advanced, it is quite common for patients to exhibit subnormal temperatures, particularly during the forenoons, for days, weeks or months in succession.

Nervous System: This probably does not suffer much as a direct consequence of amebic infections, but of this I am not at all sure. There are many cases of neuritis, neuralgia, etc., which are so closely connected with the disease that until we are more fully acquainted with the exact method of the action of amebas in other parts of the body, our opinion can only be based on supposition.

Pain: The subject of pain in general, however, may be conveniently discussed here. Its variety and intensity in this affection is very great. It is partly a direct consequence of lesions and partly the result of more remote and sometimes unexplainable causes.

Tenesmus is more often an indication of complications or severe secondary involvement than of amebic infection. It is never present in the latent forms and is usually absent or very slight in those of moderate severity; but during acute exacerbations of either of these, and particularly when diphtheritis or other secondary infection, including that of *B. dysenteriæ Shiga,* is present, it may be very severe. It is much less severe or more likely absent when the lesions of whatever type are in the cecum or upper part of the colon.

Colicky pains are not infrequently seen, and even severe acute intestinal colic sometimes supervenes, especially when there is marked catarrh of the small intestine.

Dull, aching, somewhat indefinite abdominal pain is one of the most frequent prodromal symptoms, and quite frequently it is persistent during the disease. Sometimes it is so severe and constant that rest is impossible for days or weeks at a time. Though most usually complained of as being of maximum intensity along the course of the colon, as general careful palpation will show, not unusually it is found only in the region of the cecum and is sometimes complained of in the muscles of the back. Such pain may be due to the processes going on in the bowel, and, again, as demonstrated by postmortem examination, it may be the only indication during life of the most extensive serous inflammations and adhesions. These pains are often most active in the night, even in the mildest cases of infection, and may interfere seriously with the patient's rest.

Pains described by patients as "heart burn in the abdomen" may be general or more frequently local. When active lesions are low in the sigmoid and rectum, these and what are described as burning pains are frequent. The latter may be intense about the rectum, and may sometimes extend down the backs of the thighs and even to the calves of the legs. Old sciaticas are often "fired up" under these circumstances, and the beginning of sciatica is associated with such cases often enough to be suggestive.

Pains simulating those in appendicitis have been more fully discussed in Part 2 of *Bulletin* No. 18, Bureau of Government Laboratories, and in the Journal A. M. A., April 8, 1904. They are probably the most important with which we have to deal, because their true interpretation is so vital to the patient and because they are of such general occurrence in all varieties of amebic infection, from the latent to the gangrenous, with or without the presence of amebic or other forms of appendicitis.

Neuralgias, myalgias and arthralgias are met with too frequently to allow them always to be considered accidental associations. Persistent, dull headaches, particularly of the back of the head and neck, are also not uncommon. The genitourinary and respiratory systems and the organs of special sense rarely contain lesions which produce symptoms of any importance in the uncomplicated disease. The same is true of the joints and the osseous system, though complications may involve any of these structures.

DIAGNOSIS.

There are no classical symptoms in the disease, and hence an absolute diagnosis can be made only by microscopic examination of the feces.

In remote areas where the infection is endemic and where microscopic facilities are not available, one would be justified in making a diagnosis for purposes of treatment from clinical manifestations alone, but where laboratories are accessible this should never be done.

If one remembers the multiform clinical pictures which have already been discussed and watches the case for some time, a diagnosis of amebic infection may reasonably be inferred, but it must be borne in mind that the clinical picture does not in general differ materially from that often seen in diseases with an entirely different etiology, and, further, that there is not a single symptom or group of symptoms which is confined to this disease alone.

The following are the most important clinical manifestations in a question of diagnosis:

1. The bowel evacuations, particularly their odor, and the presence or absence of blood. Their consistency, quantity, frequency and the presence or absence of mucus, are much less important.

2. Abdominal soreness, which is increased on pressure and extends particularly along the colon, is most common and, taken singly, is one of the most valuable symptoms. Its diagnostic importance is greatest when of maximum intensity over the cecum and ascending colon.

3. So-called "indigestion" headache, general lassitude, with nausea or pain below the stomach after eating, etc., is quite common, but is also prevalent at other times, so that but little importance must be attached to it alone.

4. Loss of weight, especially in the presence of a good appetite, is quite important and is the best guide to the progress being made by the infection.

As already stated, neither one nor all of these symptoms taken together are sufficient for an absolute diagnosis; but when taken together in cases where careful palpation reveals a thickened, tender colon in places where it may be felt, they make the nearest approach to a sure diagnosis possible without microscopic examination of the feces.

The question as to whether the presence of amebas in the feces is always absolutely diagnostic of an infection of the colon has already been discussed. It may be that such is not always the case, but I believe that it is so nearly so that such an occurrence, at least in the tropics, should be considered diagnostic, at any rate for purposes of treatment. Such a conclusion is all the more justifiable when we consider the great certainty of good results in treatment instituted early, the long incubation period or latency which severe cases may show, the inability ever to establish a more certain diagnosis in those cases of light infection which terminate in recovery and, finally, above all, *the great reduction of the danger of liver abscesses by instituting early treatment.* It will be remembered that, according to statistics from many places, including Manila, over 20 per cent. of untreated patients or those not treated by enemas have developed liver abscesses, and that in a very large number of patients treated by my colleague and myself in private practice during the last few years, along lines laid down in *Bulletin* No. 18, there have not been more than two cases of liver abscess which developed after treatment was instituted. Inasmuch, then, as a correct diagnosis can be made only by finding amebas in the intestinal contents, and as their presence here, at least for purposes of treatment, are to be considered diagnostic of infection, regardless of clinical symptoms, the best method of determining their presence or absence should be part of our subject.

This is not always an easy matter. When there is active clinical dysentery, a microscopic examination of one of the passages will usually reveal amebas, but even here single or even several examinations will often yield negative results. The specimen for examination should, when practicable, be one obtained by some hydragogue cathartic, because the infected area frequently includes only a portion of the colon, and by this means the specimen is more certain to contain feces from the entire track.

For the same reasons, the method of extracting a specimen through a speculum can be of maximum value only where the lesions are in the lower bowel. For obvious reasons castor oil is not a satisfactory cathartic for this purpose, and specimens obtained by enemas are likewise unsatisfactory.

The specimen should be as fresh as possible when examined, for, while amebas will usually remain motile for several hours and sometimes for days, in many instances they lose their motility in a very short time. In Manila, a warm stage will never be found necessary, and a diagnosis had best not be made from any but motile organisms.

Usually no difficulty will be experienced in differentiating amebiasis from other diseases, but when other troubles exist as complications or associated diseases, which is of very frequent occurrence, the solution is often not so simple. Suffice it to say here that in practically every instance in which such complications or associations do exist they are rarely of a nature which offers contraindication to the institution of the usual treatment of amebiasis, and, therefore, whether or not the nature of the complicating trouble is determined, treatment of the amebic infection should be prosecuted.

PROGNOSIS.

The prognosis in this infection should take several points into consideration, and the evidence in each individual case should be carefully weighed before an expression of opinion is justifiable.

Fortunately, in Manila, owing to the good results of treatment, the physician is rarely called on to say very much; but in the more prolonged and persistent cases prognosis is eagerly sought by the patient and his friends. In general, under proper treatment recovery is the rule in young, well-nourished adults, in whom the disease is not of too long duration.

The principal determining factors in giving such prognosis are the manner of treatment, age, nationality, general condition of the patient and duration of the disease at the time treatment is instituted, reaction to treatment, the presence of complications and associated diseases, and, finally, the location of the amebic lesions.[5]

It must be remembered that in a certain percentage of cases, particularly in children and natives, the patients recover from the disease without any treatment whatever. On the other hand, one occasionally sees a patient in whom the disease is progressive from the first, and death is not apparently delayed by any form of treatment.

The disease is generally milder in children and in natives of the tropics, and its course is more often shorter and its mortality higher among the aged. Alcoholics apparently are less frequently infected, but when once the disease is established the gravity of the prognosis is increased. Previous good health and good general physical condition are favorable factors. The shorter the duration of the disease at the time treatment is instituted and the greater the tolerance for enemas the more favorable the prognosis.

The presence of complications or associated troubles, such as liver abscess, severe hemorrhoids, fistula or fissure in ano, and many others less frequent, materially decrease the chances of ultimate recovery. Probably most important of all, however, is the location of the lesions. As a rule the higher up the lesions, the greater the mortality and the less active the clinical dysentery. Severe infections of the cecum, unless treated early and carefully, are always serious.

CONCLUSION.

In conclusion, I wish to emphasize the fact that intestinal amebiasis (amebic dysentery) manifests itself in a much broader and more comprehensive clinical picture than is generally allotted to it.

Waiting for bloody mucus stools to appear before making a diagnosis and instituting treatment is responsible for a large percentage of the present mortality from the disease in Manila. Such stools sometimes appear early in the disease, more usually after considerable damage has been done, and occasionally are never seen before a fatal termination or recovery.

Suppose, for example, that by treating every patient in whom motile amebas are found, as recommended in this paper, we do occasionally treat a person who would have recovered without treatment, or possibly would never have had an active lesion, are we not justified, when we consider that by such procedure established early, without waiting for clinical dysentery, we increase many fold the chances of recovery of all patients?

DISCUSSION.

Dr. George Dock, Ann Arbor, Mich., said in regard to the importance of distinguishing the latent, that he was fortunate enough to see a latent, mild or variable case very long ago, and he has already called attention to it. Briefly, the history of the case is as follows: The patient was a man who, for several months, had no loose stools at all and no diarrhea, and was absolutely free from any symptoms ordinarily referred to as dysenteric, yet he developed a liver abscess which was operated on and proved to be amebic. The patient died a few days later, and it was shown that not only were there lesions in the cecum, but also in the upper part of the large intestine, as well as in the liver. The stools Dr. Dock examined and found no amebas or other evidences of the disease. If the patient had been under his observation a longer time the diagnosis might have been made prior to death, especially if saline cathartics, as Carlsbad salts, had been given to facilitate the examination of the stools. In diagnosis, the most important thing is the proper examination of the stools, and this has been much neglected because it has been supposed to be so difficult. By giving Carlsbad salts, stools can be secured whenever wanted, and there is really no difficulty in finding the amebas, even in cool media or in cool rooms. As an important and practical aid in this examination of the stools, they should be examined, not in deep vessels, but in flat vessels, the broad low granite dishes answering the purpose very well. A certain amount of practice is necessary in order to be sure always that what is seen are really amebas. Dr. Dock likes the modification of Jenner's stain, which he believes to be as good as the specific stains. His experience in the South shows that it is comparatively easy to treat this disease if it is seen at the beginning. Cathartics should be vigorously given, and irrigations of any kind are useful, his preference being for strong saline solutions. In the chronic cases the treatment is more difficult. These latent cases are the ones which are likely to be seen in this country. At the Saratoga session, Dr. Dock was able to report such a case, and within the last year he has seen another example which occurred in a man who had never been outside of the United States at all, and yet he had a severe infection with *Amœba coli.* The greatest care possible is demanded in the treatment of the patient. It is very necessary that constipation should be avoided. Instructions regarding the diet may vary greatly. He has seen beneficial effects from the use of ipecac used after the manner of Strong, covering it with salol. About one year ago he saw an interesting case of amebic infection from the Philippine Islands. The patient had amebic dysentery, as well as uncinariasis and the *Tricocephalus dispar.* He was treated for uncinariasis with thymol, and the amebic signs then disappeared as well. Although this is spoken of as a tropical disease, it may occur in other parts of the country. Though the clinical picture varies greatly, the diagnosis can be made, and the treatment is becoming more and more satisfactory.

---

[5] In my last 100 completed cases treated in private practice including all types and stages of the disease, 96 patients have permanently recovered without leaving the Philippine Islands. There has been one death and three have returned to the United States.

DR. H. R. LEMEN, Alton, Ill., stated that he has had two years' experience in the Philippines, and made careful examinations of 532 males and 53 females who were taken there as prisoners without any apparent evidences of the disease whatever, and he found 91 males and 11 females with amebas. Among 50 soldiers there were found 10 cases of liver abscess.

DR. STANLEY BLACK, Los Angeles, Cal., asked Dr. Musgrave for the points in differential diagnosis between *Amœba coli* and other amebas which exist in the stools. Dr. Black has seen a number of cases in which amebas were present in the stools, but in which there were no symptoms of dysentery, such as one expects to find when the *Amœba coli* is present. He also asked if Dr. Musgrave considers the presence of red corpuscles diagnostic of the *Amœba coli* and if the pathogenicity for cats is of importance in diagnosis. In Dr. Black's opinion the material for examination can best be obtained by the introduction of a rectal tube. The mucus so obtained often contains many amebas.

DR. F. C. SHATTUCK, Boston, stated that he has seen one case of amebic dysentery in a man who had not been out of New England. This simply corroborates what has already been stated, that the disease is not necessarily one of the tropics.

DR. CLAUDE A. SMITH, Atlanta, Ga., said that physicians meet some cases of amebiasis in the South, but of course not anything like the number found in Manila. As an illustration of the fact that some patients appear to recover or even recover without treatment, Dr. Smith said that five years ago, at the request of Dr. H. F. Harris, he made a postmortem examination of a man who ten years previously presented clinical symptoms of a severe type of the disease. He removed the colon, but there was no evidence of any ulceration, nor any macroscopic signs of previous ulceration. This also showed that the symptoms of the patient are not necessarily an index of the extent of the lesions. He recalled one or two autopsies in which he found extensive ulcerations throughout the colon, and yet the clinical symptoms did not indicate anything serious. There was one case in a negro man, about 45 years of age, whose muscular development was perfect, presenting no signs of emaciation, and who was not considered to be in serious condition, and yet he died forty-eight hours after admission to the hospital. The colon's entire mucous membrane was found to be necrotic, and yet that man had been hard at work until two days before death. He asked if Dr. Musgrave has been able to trace these cases of amebiasis after apparent recovery, and if he has found many relapses.

DR. W. E. MUSGRAVE, Manila, P. I., said that all the questions and points brought out in the discussion have been carefully gone over in the present paper and in previous publications. (See THE JOURNAL A. M. A., April 8, 1905, *p.* 1098, and Bull. 18, Bureau Government Laboratories, Manila.) In conclusion he emphasized the fact that the symptoms produced by this affection are in no way proportionate to the danger done to the bowel.

AFFECTIONS OF THE THYROID IN CALIFORNIA.*

HERBERT C. MOFFITT, M.D.
SAN FRANCISCO.

Six years of hospital and private work in San Francisco have strengthened the conviction that affections of the thyroid, like aneurisms and early arteriosclerosis, are more common here than in many other cities of the United States. With this idea in view, letters were sent during the last months to men in each county of the state asking for information as to the occurrence of goiter, myxedema, sporadic cretinism, and exophthalmic goiter in their districts. My obligations are here expressed to many colleagues who have kindly sent reports. There seems to-day little need for review of [illegible] ophthalmic goiter with thyroid [illegible] of nervous factors can not be denied the possible influence of other internal secretions in etiology is recognized, but the gland plays a chief rôle in symptomatology (even though, as Moebius says, there may be a prethyroid stage of the disease). Despite the vast amount of work of late on the parathyroids by Gley, Edmunds, Welch, Benjamins, Jeandelizo, Moussu, Vassale and Generali, Lusena, MacCallum, Brissaud, Pineles and others, it is not yet possible to say that they color in any way the picture.

The statement of Hirsch that "our information on the endemic occurrence of goiter in North America belongs for the most part to the early years of this century and is very fragmentary" can be modified in light of articles by Richardson, by Adami on goiter in Canada, by Osler on "Sporadic Cretinism in America," by Dock on "Goiter in Michigan." *The Medical Sentinel*, February, 1904, had an editorial on goiter in the northern Pacific states, and lately Musgrave of Washington described the great frequency of the condition in the Wenatchie and Puyallup Valleys in animals as well as man. Praslow years ago reported cases of cretinism among Indians near Cape Mendicino, Humboldt County, and among the Spaniards in Southern California. Osler in his article on sporadic cretinism wrote: "Praslow's account of the occurrence of cretins in California I have not seen, but I have letters from several correspondents in that state who know nothing of its existence at present, while in the State Insane Asylum at Stockton, Dr. Hoisholt tells me there are only two cases." It is interesting to note from reports of Dr. Gross of Eureka and Dr. Delamere of Ferndale that goiter is common in Humboldt County, not far from Cape Mendicino, although accounts of only two cretins are sent from that district. I have seen two cretins among Indians near Kelseyville, Lake County. Reports from Southern California do not substantiate the account of cretinism among the Spanish settlers.

GOITER.

Data concerning goiter must of necessity be unsatisfactory, as slight or even moderate enlargements of the gland are often overlooked; and, as in all statistics, the personal equation of the reporter must be considered. A few weeks since a physician came personally to report the absence of thyroid affections in his district and presented himself a good example of myxedema. The testimony of physicians from counties about San Francisco Bay (Marin, Alameda, Santa Clara, San

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Mateo, and San Francisco), confirms the idea that moderate enlargements of the thyroid are common. Most patients are natives of California, and inheritance from parents coming from endemic goiter regions of Europe would seem to play little part. Dr. Eleanor Bancroft, Berkeley, writes me that 5 per cent. of the young women entering the University of California in 1904 had enlarged thyroids. Since January 1, 1905, I have noted moderate enlargement in 75, large goiters in 8 patients out of 546; 14 cases were in men. This would give a percentage of 15.2 in individuals, nearly all of whom are native born, or who have lived for years in California. In one family five members have goiter, in another three. In a number of young women accompanying nervous symptoms seem definitely referable to thyroidism, but in the majority of instances the enlargement is without influence on the general condition.

Dr. Pope of Watsonville has noticed 12 decided goiters in 1,200 cases, but writes that small tumors are much more frequent. Reports from the southern part of the state (San Diego, Riverside, San Bernardino, Los Angeles, Santa Barbara, Kern, Tulare, Kings, and San Luis Obispo counties) would indicate that goiter is less common there than in the bay counties. Dr. von Zwalenberg of Riverside says it is much less common than in Michigan. Dr. Sanborn writes from Redlands that there are about 40 cases of moderate goiter in the practice of different physicians there. Los Angeles and Pasadena physicians report the condition uncommon, and men from Fresno, Tulare and San Luis Obispo as rare. Through the kindness of Dr. P. K. Brown, however, I am able to quote a letter from Miss Jacobs of the Los Angeles Normal School in which she says goiter is common in the young women in attendance, and that not a few report other cases in the family—one term 8 per cent. had enlargement of the thyroid.

The interior mountain counties of the central part of the state seem much less affected. Letters from Madera, Merced, Mariposa, Stanislaus, Tuolumne, Amador, El Dorado, Placer, Nevada, Sierra, Butte, Yuba, Sutter, Yolo, Colusa, San Joaquin report few cases. Dr. W. A. Briggs thinks moderate sized goiter fairly common in Sacramento county. Dr. Dempsey of Vallejo, Solano county, sees enlarged thyroid in 4 per cent. of his patients. Lake, Napa and Sonoma have few cases. Dr. Margaret Evans mentions a family in Calistoga, Napa county, four members of which have goiter. Of the northern coast counties Mendicino and especially Humboldt appear to show endemic goiter. Dr. Bond of Ukiah writes: "I can only state in a general way that thyroid enlargement is very prevalent in this vicinity, most cases being of American parentage and without symptoms. Dr. H. G. Gross of Eureka writes that he sees a number of cases practically all of which come from an area about ten miles long and three wide, partly in the valley and partly in the foothills. Dr. H. S. Delamere of Ferndale, within the district spoken of by Dr. Gross, says: "Thyroid enlargement is quite prevalent here." Dr. Jorgensen of Fortuna, Humboldt county, however, sees but few cases. Professor A. C. Lawson of the University of California, in a paper on "The Geomorphogeny of the Coast of Northern California," describes the peculiar formation known locally as the "Wild-Cat Series" that extends through Humboldt county. Its peculiarity depends on the softness of the beds in general, the frequent alternation of harder and softer rocks, and the deep erosion of the Eel River and its tributaries. It would be of interest to map out the goiter region with reference to this peculiar terrane. The entire peneplain consists of marine deposits, pliocene and post-pliocene, with a coastal strip of later mesozoic and tertiary rocks. The reports deal but slightly with questions of etiology—mention is made simply that most cases are seen in women and that enlargement of the neck has often been first noted during pregnancy. In several instances note is made that the goiter has enlarged with each pregnancy. No mention is made of goiter in animals, but I have seen it in one horse and two dogs in the past year.

MYXEDEMA.

Reports here are less equivocal. The bay counties again show the greatest number of cases partly on account of greater population, and partly because cases from a distance drift to San Francisco as a center. I have descriptions of 30 cases throughout the state. Tehama, Monterey, Sacramento, Santa Barbara, Riverside, Stanislaus, Marin, Yuba, Mendicino, Santa Cruz, Yolo, Kern and Colusa report one case each; Solano, Santa Clara, Butte, two cases; Fresno and Los Angeles three, and Alameda sends five. San Francisco physicians send accounts of 43 cases, without duplicating any of the reports from other counties as far as can be ascertained. Adding 10 of my own, there is a total of 53 cases from San Francisco, and 83 throughout the state. I have purposely omitted reports of doubtful cases, accounts of *formes frustes,* or descriptions of exophthalmic goiter with myxedema. In 50 cases in which mention was made of sex, 39 were women and 11 men. Age varied from 18 to 64. Thirteen had decidedly large thyroids, the myxedema resulting from changes in old goiters. In 22 the thyroid was not palpable, and no mention of the gland is made in 31. Of 55 ten were of foreign birth, but had been years in California. Twice the condition resulted from operation on goiter. Two of my cases were born in Norway. Two had spent some years in Alaska, and symptoms developed while there. Emphasis in description is laid chiefly on skin, voice, and mental changes and disturbances in locomotion. Three women had frequent epileptiform attacks which did not yield to thyroid medication, although skin and mental conditions improved. A woman reported by Dr. P. K. Brown had profuse menorrhagia before thyroid treatment was begun.

Some years ago I saw myxedema in a girl of 20 whose mother had just died of the disease. Skin of the face and over the extensor surface of the arms was thick and dry, there was a diffuse growth of hair over the face and arms that had appeared during the last year; the voice was remarkably deep and harsh, menstruation had ceased ten months. The fundus showed atrophy of the nasal side of both discs, and color vision was limited in the temporal half of both fields. In all probability change in the hypophysis was the cause of eye symptoms and perhaps of the hypertrichosis. Menstruation appeared under thyroid extract and the skin grew better, but the girl committed suicide and no autopsy was obtained. Uhthoff described blindness in a boy of 6 with myxedema; vision improved under thyroid, and this was attributed to shrinking of the hypophysis. Coppez describes retrobulbar neuritis from thyroid feeding, but no instance has fallen under my observation. Endeavor has been made chiefly by Brissaud, Murray and Pineles to distinguish between myxedema of thyroid and of mixed thyroid and parathyroid origin. They would attribute considerable influence to the parathyroids in determining sexual and mental changes. In cases with profound mental changes, therefore, we would look more closely for other signs of disturbed parathyroid function—particularly for evidence of tetany or convulsive seizures. Only one of my cases was mentally profoundly affected, and here the Chvostek and Trousseau phenomena were constantly absent. In one woman with most marked exophthalmic goiter and epileptiform attacks the Chvostek phenomenon was present on two examinations; partial thyroidectomy led to disappearance of all symptoms, no tetany developed, and the patient has been well three years.

FORMES FRUSTES.

Very interesting to me are the *formes frustes.* I have notes of 11 cases, 5 men and 6 women, all of whom presented the same clinical picture, and in whom definite improvement took place under thyroid medication. One was a woman of 35, two were men of about 45, and the others were from 55 to 65; the sister and daughter of one woman had goiter; one man and two women had small goiters. Such cases are fairly common in the literature of thyroid insufficiency. Some of these people have for years had dry skins, thin hair, pains between the shoulders, paresthesiæ, joint pains. In two of my cases influenza seemed a factor in precipitating thyroid symptoms—skin changes, nervous unrest and tachycardia. Most characteristic is the dry skin, scaling of the scalp, thinning of the outer half of the eyebrows, loss of hair on the neck and in the axillæ. Fat pads occur above the clavicles, and not infrequently there is a large pad over the upper dorsal vertebræ, a bib-like roll across the neck and upper sternum, thickening of the subcutaneous tissue across the lower ribs and above the elbows and knees on the extensor surface. Pains in the knees and ankles and occasional "giving away of the legs" are frequent. The voice has often a peculiar deadened husky quality.

Five instances of infantilism of the thyroid type described in detail by Brissaud, Meige. Hertoghe and others have come to my notice in the past two years. Two boys of 14 and 18 grew quickly under thyroid treatment, and showed increased development of pubic and axillary hair and of genitalia. One boy of 17 was excessively fat and had complications of muscle dystrophy and coxa vara. Another boy of 16 died of diabetes; thyroid extract had no effect on the sugar elimination. The fifth boy had acute nephritis and uremic convulsions.

SPORADIC CRETINISM.

In Osler's article on "Sporadic Cretinism in America" are included three cases from California, two of Dr. Hoisholt from the Stockton Asylum and one of Dr. Osborne from the Home for Feeble-minded Children at Glen Ellen. I have reports outside of San Francisco of 37 cases that from description [illegible] seem definitely examples of cretinism. [illegible] and chondrodystrophy cases are not [illegible]ssification. Of these, seven were born outside of the state in Mexico, Wisconsin, Illinois, New Zealand, New York, New England, and four have died. Doubtless the list can be extended by a more thorough canvass at some later day. Dr. Dawson, superintendent of the Home for Feeble-minded Children at Glen Ellen, Sonoma County, writes that there are several cases of idiocy of Mongolian type and a few cretins, but these are not included in the above. Physicians in San Francisco send me accounts of 28 cases, to which I can add 7 of my own, making a total of 61 cretins now living in the state, and all native born. The majority of reports chronicle absence of palpable thyroid enlargement. No valuable data as to etiology are available. Dr. Frances Sprague reports a girl of 2 from the Children's Hospital in San Francisco who died of general tuberculosis, with extensive tubercular changes of the thyroid. Dr. Millicent Cosgrave sends me notes of a girl of 5, born in New York. Mother and grandmother had goiter, and the maternal grandfather died of tuberculosis. The child seemed normal during the first year, and walked at 18 months, at 3 had measles and later tuberculosis of the glands of the neck. Since then she has not walked well, has backache, is nervous, skin dry and rough, appearance that of a cretin, is extremely stupid, abnormally developed—is as tall as a child of 10. Breasts, hips and limbs look like those of a girl of 16. The mental condition has improved under thyroid treatment. Brissaud calls attention to tuberculosis of the cervical glands as a cause of myxedema. In one of my cases symptoms developed soon after diphtheria. Dr. Dempsey of Vallejo reports seeing a cretin whose mother had a large goiter, with myxedema. Dr. Sprague mentions a girl of 14 with a big thyroid, another of her cases was but 18 months old. In a case of mine—a girl of 7—the parents were from the south of France. From the history, the father's sister was probably a cretin, and a brother of the patient died at 6 months in a condition suggesting cretinism. Dr. P. K. Brown tells me of two brothers born in San Francisco whose parents are German and perfectly well. In the greatest number of cases parents were born in California. In three instances parents were from the Azores, in two from Austria, in two from southern Italy, in three from Ireland. Detailed descriptions will be left to a later paper, but photographs of ten cases are now available.

EXOPHTHALMIC GOITER.

This affection would appear to be much more common in the counties about San Francisco Bay than in the other parts of the state. Dr. Emmet Rixford of San Francisco sends me notes of 8 primary cases and 3 secondary to goiter of years standing; Dr. T. W. Huntington, 5 primary and 8 secondary; Dr. W. I. Terry, 10 primary; Dr. J. H. Barbat, 10; Dr. Mac Monagle, 29. Physicians content themselves, as a rule, with saying that the affection is "common" or "decidedly frequent." Dr. Abrams has seen 30 cases. My own list includes 33 well marked cases of exophthalmic goiter, excluding *formes frustes.* Of these, 9 were male and 24 female; 7 occurred in patients with goiters of years' standing. Most observers agree as to the thyroid factor in the disease, but emphasize the influence of an unstable nervous system and the immediate effect of nervous shock. Dr. J. H. Barbat saw 3 cases develop acutely after fright. Some few years ago in the wards of Dr. Kerr in the City and County Hospital of San Francisco I saw an Italian with unusual history. Three weeks before, in perfect health, he had been out prospecting in one of the interior counties, had strayed off, and was lost in the mountains for two days. He was sick from that time, excited, restless, could not sleep, vomited, grew rapidly thin, had breathlessness, palpitation, trembling, could scarcely walk. Examination showed exophthalmic goiter, with cardinal signs, emaciation, terrifying unrest. For days he remained the incarnation of terror, but then slowly changed to the more uneventful stage of the disease.

In a woman under the care of Dr. Abrams, the father and brother showed symptoms of the disease. Two of my patients were mother and son and two brother and sister. The mother of one young woman under my care has myxedema. Dr. Crowley of Oakland reports exophthalmic goiter in mother and son. Dr. F. L. Adams of Oakland reports the disease in mother and daughter; the mother is from Derbyshire, a well-known center for goiter. Another of his cases gives history of the same affection in her mother and mother's mother.

In the reports of simple goiter, frequent mention is made of associated nervous symptoms, tachycardia, and tremor. These cases are similar to the ones described by Mikulicz and Rehnbach, by Kocher and others as instances of thyroidism associated with goiters of varying types. They form a transition to true exophthalmic goiter developing in individuals who for years have had goiter without symptoms. In a woman of 41, seen two years ago, there had been a marked goiter for 18 years; eight years before nervous symptoms became bothersome; there was exophthalmos, tachycardia, tremor. Swelling of the eyelids and a peculiar brawny infiltration of the side of the neck and face led to a diagnosis of complicating kidney disease, but this was not present. The swellings were analogous to the hardening of the skin of the face reported by J. Schulze, a firm infiltration not like true scleroderma nor yet of the consistency of myxedema. In a woman seen four years since, there had been a moderate goiter for years. During pregnancy signs of myxedema, as thinning of the hair, dry skin, supraclavicular pads, were reported to have developed and to have disappeared under thyroid extract. Unfortunately with continuance of the thyroid extract a typical exophthalmic goiter developed, which was marked by all cardinal signs when I saw her.

Breuer of Vienna and Gautier of Geneva have lately emphasized anew the occurrence of exophthalmic goiter after treating goiter with iodin preparations. Breuer cited a case developing after the use of K I—a syphilitic woman who had shown no previous struma. Rilliet, 1860, and Lebert, 1862, gave many instances of iodism in goiter cases. Theodor Kocher, in a recent article on "Die Therapie des Kropfes" in the *Deutsche Klinik*, gives a masterly review of the action and dangers of iodin compounds. His conclusions are based, in part, on the studies of iodin elimination in normal individuals and cases of goiter by A. Kocher published in vol. xiv of *Die Grenzgebieten der Medizin und Chirurgie*. He makes clear that most symptoms are due to thyroidism rather than iodism. With quick recession of a goiter, danger of intoxication greatly increases, but the disappearance of a struma is not necessary for production of symptoms. The smallest dose of K I may cause severe thyroidism in exophthalmic goiter or cause rapid emaciation in the newborn or in pregnant women. "In excited, unduly animated, thin individuals who always have congested faces. who tremble at nothing, get palpitation on the least occasion, and who sweat easily, one has to deal with beginning thyroidism, and one may cause outspoken exophthalmic goiter through careless use of iodin."

I have had several cases of iodism after small doses of K I in patients with small goiters, and now make it a rule to examine the thyroid and to look for signs of exophthalmic goiter before prescribing it. In one young man in whom K I, syr. acid. hydriod. and tr. iodi gave toxic symptoms, iodipin was given hypodermically with impunity, confirming the observations of Schuster and Lesser; it could be demonstrated in the tissues by x-ray plates six weeks after injection. According to Gautier, the source of plant and water iodin supply is the iodin "dust" given to the atmosphere by sea water. Rilliet of Geneva thought a change to the seashore might develop symptoms of exophthalmic goiter in patients with struma. It is an interesting speculation whether the number of cases about San Francisco are in any way due to the prevailing strong sea winds. It is certain that a few cases from the interior have done worse on the coast, and insomnia is apt to be a bothersome feature of the change. In eight of the reported cases there is noted a combination of exophthalmic goiter with myxedema, but description lacks sufficient detail to admit such classification. It is well known that edema and skin infiltration of different kinds may occur in pure exophthalmic goiter. Kocher describes a number of such cases. Dr. Rixford reported a remarkable case of a young woman of 29, who was married a few weeks before contracting scarlatina. Three months later a goiter, the size of a walnut, was observed. One year later there was rapid growth during pregnancy, and still greater enlargement after a second pregnancy two years later. General edema, tremor and choreic movements were noted, besides the usual symptoms. Edema rapidly disappeared after operation. In two of my cases, fat pads and hard infiltration of the skin over the lower ribs persisted after operation. In a discussion on "Internal Secretions" two years ago (reported in the *Clinical Journal*), Horsley described certain anomalous cases of myxedema, with a peculiar excitable mental state, inability to exert, symptoms of heart insufficiency, and fat pads or diffuse skin infiltration. He regarded them as combinations of athyroidism, with a certain amount of aberrant internal secretion, the "dysthyroidism" of Moebius. He advises in treatment almost total removal of the gland, and then supplementing its secretion with thyroid extract. I have under observation for two years and a half a woman who lived abroad years ago, for some time in centers of goiter, such as Geneva and the Pyrenees, and who for years had the nervous and heart symptoms of exophthalmic goiter. There has never been exophthalmos, but at times there is a fixed stare or glare that to me is rather characteristic. For six months the pulse was never below 100, and during attacks of palpitation 160 or more. There are at times remarkably large supraclavicular pads, such as are seen in myxedema, and a diffuse bib-like pad of the same tissue, feeling like half solidified fat, stretches across the front of the neck and down irregularly four or six inches below the clavicles and across the sternum. An apron of the same kind extends across the epigastrium and lower ribs. The case is similar to those reported by Horsley. Of chief interest is the variation of the condition under alternate treatment with rodagen and iodid of iron as described below.

Formes frustes of exophthalmic goiter would require a separate paper. There is danger in labeling too many indefinite nervous affections with this convenient diagnosis, which only a combination with cardinal symptoms should justify. I have seen enlargement of the thyroid, with nervous symptoms and tachycardia, the result of masturbation in young men. Since my attention was called to it by Ortner of Vienna, I have seen the same thing, the result of excessive tobacco smoking in boys. Of interest in considering eye symptoms of the disease are the reports of Arslau, Spiegler, and Holz concerning the occurrence of exophthalmos in adenoid cases and its disappearance after operation. During the last year Dr. C. M. Cooper and I have been testing the value of von Graefe's sign in diagnosis. It was curious to note the occasional development of this and Stellwag, with other symptoms of mild thyroidism, after administration of K I. Our results confirm the observations of Sharkey and of Flatau that the sign is frequently seen apart from thyroid disease. It was particularly common in Italians, probably because of the greater tendency to keep the eyes widely open while talking.

THERAPY.

The goiters seen here rarely demand operation on account of their size. Dr. Rixford, Dr. Terry, Dr. Rosenstirn, however, send me accounts of 20 operations for cystic or adenomatous goiter. The necessity of caution in the treatment of goiter, and particularly exophthalmic goiter, with iodin compounds or thyroid extract has been sufficiently emphasized above; the senseless administration of thyroid extract in large doses for obesity, arteriosclerosis, and other cases of supposed thyroid insufficiency should be discountenanced. Cunningham has attempted to prove that toxic symptoms are due to contaminating cadaveric derivatives and not to the active thyroid principle, and claimed that fresh glands may be given with impunity in exophthalmic goiter. The occurrence of well-marked exophthalmic goiter after administration of K I or iodothyrin in goiter cases would, however, speak decidedly for the theory of hyperthyroidization.

The reports of treatment in myxedema and cretinism are enthusiastic. It is usually not necessary to give large doses of a good thyroid preparation; in cretinism I begin with one grain daily and rarely go beyond 5 grains. Many myxedema patients need only small doses, even at first; some of them can not take more than 2 or 3 grains without disagreeable nervous symptoms. Dr. Ebright tells me of a man of 64 who had severe rheumatoid pains each time the dose was increased beyond two or three grains daily. Bramwell speaks of an acquired intolerance, and mentions a case in which large doses were well borne, but later even 1/20 of a tablet produced marked toxic symptoms. Paresthesiæ and other unpleasant symptoms may be modified by giving Fowler's solution at the same time. Opinions are in accord that preparations representing the whole gland can not wholly be replaced by the active principle iodothyrin. Bramwell, Magnus-Levy, Warner von Jaurenegg report encouraging results in the treatment of endemic as well as sporadic cretinism.

Until recently medical treatment of exophthalmic goiter was limited to electricity, hygienic measures, and a long list of drugs for symptomatic use. It is very difficult to judge of the efficacy of any method of treatment in an affection notoriously so uncertain in course and symptoms. I have seen good results from long-continued faradism, as recommended again of late by Horsley, the patients use the battery themselves for an hour or two daily, fastening the electrodes over the neck, front and back. With the treatment suggested by Wm. Thompson, I have seen no effect in marked cases. Strontium or calcium bromid—30 to 45 grains daily—or the bromid of quinin, 15 to 30 grains daily, as recommended by Forscheimer and Shattuck frequently modify nervous symptoms. Phosphate of soda, suggested by Trachewsky and indorsed by Kocher, or the glycerophosphate of soda, certainly control tachycardia and nervous unrest in not a few instances. Belladonna I prefer to digitalis or strophanthus; salicylates, sulphanilate of soda, intestinal antiseptics have availed little.

Despite reports of Goutschomkov and Mankovsky, endeavors to produce a specific thyreotoxic serum have as yet been abortive. Gley first suggested that deficiency of parathyroid function might be a chief factor in etiology of exophthalmic goiter. MacCallum found the parathyroids four times in eight operations for exophthalmic goiter; twice they were smaller than usual and twice degenerated; in one acutely fatal case none were found. Benjamins found them apparently normal in three cases. Moussu saw no result in one case from feeding parathyroids of cows. MacCallum reports feeding 12 glands daily for some weeks in a case of moderate severity without effect. From evidence yet at command it is not possible to say that the parathyroids in any way influence the affection.

It is not possible to dwell on results of operative treatment, though I am convinced that many cases belong to the surgeon. Five of my cases have gone to operation. In four improvement was almost immediate and the patients have remained well. One woman died four days after operation, with symptoms suggesting parathyroid insufficiency. It has seemed to me that more attention in operating should be given to the statement of Horsley, that division of the isthmus is sufficient to lead to retrogressive changes and shrinking in the rest of the gland. I have had no experience with the *x*-ray treatment as advocated by the Mayos and Beck.

In the last years effort has been made to develop a specific treatment of exophthalmic goiter. Ballet, Enriquez, and Lanz were pioneers in the movement. Lanz suggested that milk of dethyroidized goats might contain substances [illegible] exophthalmic goiter poisons. Burgh[illegible] from Leyden's clinic first used serum from a myxedema patient with encouraging result, and later introduced "rodagen," a precipitate from the milk of dethyroidized goats. Leyden, in *Die Medicinische Klinik*, reviews results attained and thinks them definitely favorable. Improvement is noted in three or four weeks, but treatment must be continued for months. Kollaritis reports three cases treated four to six weeks with rodagen without effect. Kuhnemann reports betterment in one case under 6 grams of rodagen daily. In 1901 Moebius communicated three cases somewhat improved by serum of dethyroidized goats. This has been put on the market by Merck and is given internally in 5-gram doses every second day, being administered in wine. Moebius has since reported benefit in 2 cases, Schultes in 1, Rosenfeld in 1, and Indermans, Boerma, Hempel, Lomer, Duerig, Peters, and Thienger in others. Thienger gives account of an acute case responding quickly to the serum, of two with improvement, and of one with no result.

Such a new method of treatment must be most conservatively judged. I have had experience with rodagen in three marked cases over periods of four to eighteen months. In one severe case, 6 grams daily were given for four months with no appreciable effect, and the woman was later operated on successfully by Dr. T. W. Huntington. In a woman with marked nervous symptoms, insomnia and tachycardia, all symptoms seemed definitely to improve under five months' treatment with 6 grams daily; the moderate exophthalmos is unchanged, but the pulse rate is normal and the struma is smaller. A third woman has been taking 6 grams daily, off and on, for eighteen months. She had suffered from tachycardia, insomnia and nervous unrest for years. Sodium phosphate, bromids, salicylates, bromid of quinin and electricity did not control symptoms, and she refused operation. She had supraclavicular fat pads and the peculiar skin infiltrations described above. Rodagen has seemed to control the pulse for months as nothing else did, and she is enthusiastic over its effect on insomnia. After four or five weeks of steady use, she complains of depression and weakness, and has to stop for two weeks. Fat pads increase during rodagen administration, and two or three times the experiment has been tried of giving her iodid of iron in small dose. This each time promptly brings return of tachycardia and nervous symptoms, but modifies skin infiltration. Rodagen would seem to be of some benefit in these cases, therefore, but I would pass judgment only after a long series of cases. My experience with thyreodectin has been too limited to report. Dr. W. F. Cheney mentioned a case in which it seemed to control the heart symptoms. Dr. P. K. Brown tells me of a woman who grew worse rather than better under four or five weeks' treatment.

The whole question of the thyroid and its influence on development, metabolism and decay is a fascinating one. It would be valuable to report more fully the early history of patients with myxedema and exophthalmic goiter, to classify more carefully early heart, digestive and skin symptoms of the latter affection. I have seen two paroxysmal tachycardia cases that developed later exophthalmic goiter. In one woman peculiar general pigmentation with vomiting, diarrhea and weakness had led to diagnosis of Addison; Oppenheim mentions a similar case. I have under observation a man with Parkinson who presents thickening of the skin of face and extremities as described by Fraenkel and Lundborg. A woman who has twice had eclampsia came to me with a large thyroid and symptoms suggesting beginning myxedema; she is interesting in view of the work of Nicholson, Lange and others on the relation of thyroid to eclampsia. The possible influence of the thyroid in California as an etiologic factor in our very common arteriosclerotic and renal affections should be remembered.

DISCUSSION.

Dr. James J. Walsh, New York, stated that he has tried the effect of paratyphoid extract, though without getting very encouraging results. About three years ago Dr. McCallum of Baltimore suggested a connection between the parathyroids and the symptoms of Graves' disease. Many years ago Professor Gley made investigations on this subject, and came to about the same conclusion. It seemed thoroughly justifiable then to try the effect of the drug. Dr. Walsh treated four patients. In two milder cases the parathyroid seemed to be of benefit. In two severer cases, it not only gave no relief, but seemed to make some of the symptoms worse. It is doubtful if the parathyroid extract was entirely pure and free from thyroid material, although every effort was made to secure it in the pure state. It must not be forgotten, he said, that younger patients, that is, those under 25, frequently get better, even with marked symptoms, under almost any treatment. It is surprising to note how severe some of the cases are and how complete the recovery. Intermissions are extremely common, and may well be attributed to treatment when they are only phases of the disease. In older patients intermissions are rarer, and it is on these that new remedies must be tested if there is to be any reliance on the results.

Dr. E. F. Wells, Chicago, said that it has been his fortune to see many cases of exophthalmic goiter, and no patient who had been treated for any considerable time before coming under his observation, but had been given thyroid extract, and invariably with the effect of increasing the symptoms. He is sure that there is an impression in the profession that thyroid extract is the remedy for exophthalmic goiter, and a warning as to the danger attendant on such treatment is eminently desirable. Empirically, Dr. Wells has found that codein is extremely useful in these cases. He gives from one-quarter, one-half or three-quarter grain three or four times a day, and for months with perfect immunity. The patients bear it well. After an experience with this remedy for eight or ten years, he is led to advocate it as the most efficient for the purpose of any which he has any knowledge.

Dr. G. W. McCaskey, Fort Wayne, Ind., emphasizes the importance of noting the spontaneous fluctuations that occur in some of these cases of a very chronic character with any line of treatment and sometimes without any treatment. He has had two patients under observation for a period of ten or twelve years, which have exhibited these peculiarities to a striking degree. At times they appeared symptomatically well, and one of them has remained so for one period of two or three years, but in both cases the characteristic syndrome has infallibly returned. Due allowance must be made for these variations in estimating the value of treatment.

Dr. George S. Whiteside, Portland, said that the type of thyroid enlargement seen in Oregon is a very mild one and much more prevalent among women than men, and more among the young than the old. As a rule, these patients present no symptoms. The condition seems to increase at the time of pregnancy, and goes down afterward. Goiter in dogs is not uncommon in Portland. Exophthalmos seems to be the exception in both men and beasts in Oregon, but Dr. Whiteside has heard that it is much more common in California.

Dr. C. R. Grandy, Norfolk, Va., thinks that there are many more cases of enlarged thyroids in the United States than were formerly thought, simply because physicians had not been looking for them. In his own practice he has seen a considerable number of cases. When occurring in young girls he does not do anything for them. There is one class of goiter with a decreased secretion, which, as a rule, occurs in fat women with slow pulses. In such cases thyroid extract would do good. In the other class of cases there is an increased secretion which occurs in nervous people, with fast pulse rates, etc. Here the thyroid extract does harm. Dr. Grandy has seen two rather remarkable cases occurring in women past the menopause, in both of whom hysterectomy had been performed for fibromyoma for several years previously. In one there appeared to be a malignant change in the thyroid. The other woman passed from observation. In both cases there was not enough thyroid secretion; one patient seemed to improve with thyroid extract; the other had some of the symptoms of myxedema.

Dr. J. A. Lichty, Pittsburg, Pa., agreed with Dr. Moffitt that it is a difficult thing to make a diagnosis when there are so few symptoms; and yet he knows of no disease in which an early diagnosis is so essential as in exophthalmic goiter. A great deal of harm may be done in a very short time if the disease is not recognized. There may be several so-called cardinal symptoms, but only these are necessary to make a diagnosis, i. e., rapid pulse, tremor and exophthalmos. If any two of these are present it is perfectly safe to place such a patient on treatment for exophthalmic goiter. If the patients are young girls, who are fond of dancing, bicycling, gymnastic work, etc., they should be warned of the danger and the harm that might result because of an existing exophthalmic goiter. These exercises should at once be forbidden. Dr. Lichty has tried the *x*-ray treatment without any benefit in these cases. During the past ten years he has cured two patients with the rest treatment. He emphasized the importance of an early diagnosis in exophthalmic goiter.

Dr. Christian Jonsson, Clinton, Iowa, said that young people seem to have a tendency to spontaneous recoveries, and that this disease seems to be more dangerous in old people. He has observed that thyroid gland treatment is extremely harmful in most of those cases, and it is his conviction that it should never be used in exophthalmic goiter. The treatment should consist in rest and freedom from worry, besides a tonic and sedative drugs, such as we have in a so-called sumbul tablet, containing iron, arsenic, sumbul, asafetida. In a number of cases this has given Dr. Jonsson surprisingly good results.

Dr. Herbert C. Moffitt, San Francisco, declared that he did not agree with Dr. Walsh that cases of exophthalmic goiter in old people necessarily go wrong. He has seen not a few such patients kept comfortable by routine medical treatment, giving clinical evidence of further thyroid changes and slipping slowly from symptoms of exophthalmic goiter to those of myxedema. He mentioned one case in which stomach and intestinal symptoms were so marked that the affection was considered primarily a stomach one. After instituting the proper treatment the patient, a woman nearly 60, went along well, and is now showing signs of myxedema. The pulse rate is normal and the skin changes are those of myxedema. Dr. Moffitt is of the opinion, in the light of our present knowledge, that marked cases of exophthalmic goiter are helped but not cured by medical treatment, and that such patients should be referred to the surgeon.

REPORT OF COMMITTEE TO AID POSTOFFICE DEPARTMENT IN EXCLUDING OBJECTIONABLE ADVERTISING.*

C. S. N. HALLBERG, Ph.G., M.D.
CHICAGO.
H. W. WILEY, M.D.
WASHINGTON, D. C.
AND
H. C. WOOD, Jr., M.D.
PHILADELPHIA.

The following details concerning the work of the Postoffice Department, so far as it has involved the drug laboratory, present some of the problems which may be of interest:

THE ROBUSTO CASE.

All members of this Section are probably familiar with the "Robusto" case, full details of which were published in a recent number of The Journal A. M. A. In that report is clearly set forth the ignorance and stupidity of the promoter and the fraudulent nature of the advertisements. One statement in the advertisements is "there is no disease which Robusto will not cure." The would-be patient was led to believe that he was to receive medicines which were progressively increased in strength as the time of treatment continued. It was clearly shown on the witness stand that no such system was in vogue at any time by the promoter. In the case of "Robusto," there was at no time any question relative to the efficacy of the medicines employed, but the gross misrepresentations were abundant on every hand. This case presented numerous problems that we are confronted with in the case of many remedies of a similar character, but each one presents new problems to solve. For example, one promoter will claim that his remedies are new, were invented by him, are applied in a novel way, or that particular combinations produced wonderful results. The most difficult cases we have to deal with, however, are those involving results obtained by electrical appliances. It is very well known that electricity is a valuable agent in assisting in bringing about cures, but just to what extent this can be accomplished is at present largely an uncertain quantity.

OTHER SIMILAR CASES.

A few more cases similar in character, may serve to illustrate.

Dr. Stevens & Co. presented a host of medicines, largely in the form of crayons, with the contention that they were novel, in that the medicinal agent was applied directly to the affected part and in this way brought about wonderful effects. This firm also claimed that they were the originators of murituama, protargol and hyoscin bromid. One of the extremely interesting tactics of this firm was the sending of a strip of "medicated paper," advising the patient to dip the same in his urine and to return it to the company, and from it the company would make a diagnosis and inform the patient relative to the nature and seriousness of his condition. The strip of "medicated paper" proved to be nothing but litmus paper. It is almost beyond conception that a medical man, for there were medical men connected with this company, would stoop to such a downright misrepresentation.

Another firm claims to be able to cure almost all the ills that the flesh of man is heir to by a simple purgative consisting of powdered mandrake, powdered aloes, powdered capsicum and spearmint.

The Force of Life Chemical Co. claims to restore "lost manhood" and "lost vitality" by a progressive treatment consisting of a liquid containing as its chief constituent lecithin, which is present, but an examination of the remedy shows that all the packages are virtually of the same composition. This company claims to cure many infirmities by what is called by them "radium capsules." These capsules are found on examination to be free from radium.

Another great fraud met with is "aquamiel," a product claimed to be made from a Mexican plant, possessing most marvelous healing properties, and in particular stimulating the growth of the mammary gland. An examination of this product showed that it consisted of two strengths, one containing 2 per cent. of alcohol and the other 8 per cent., with 0.5 per cent. of plant extractive, the liquid being colored with caramel and sweetened with saccharin.

A Detroit firm submitted many medicinal agents, among which was a tablet consisting of capsicum, which, according to directions, was to be dissolved in water and applied to the organ as necessity required.

A product called "predigested olive oil" was also met with. The olive oil, however, was not predigested.

"Cupidene" consisted largely of red pepper, cantharides and a bitter principle.

"Ambaline" consisted for the most part of different ammoniacal salts dissolved in water.

"Liquid electricity" was another catchy term. The active constituent of this preparation consisted largely of red pepper, ammoniacal salts and volatile oils in an aqueous solution.

COMPLEXION POWDERS.

We also have to report on complexion powders and complexion tablets. One complexion powder consisted wholly of Rochelle salts. A complexion tablet consisted of extract of nux vomica, calcium carbonate and reduced iron. The unfortunate part connected with this remedy is that its promiscuous distribution was the cause of the death of a child. This was brought about by the present possibility of transmitting remedies of this character through the mails without requiring them to be marked in any way so as to inform the recipients of their poisonous nature.

---

* Read in the Section on Pharmacology of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

RULING OF THE POSTOFFICE DEPARTMENT.

For some time, it was ruled by the Postoffice Department that the transmission of poisons through the mail was prohibited. It appears pressure was brought to bear on certain officials, and as a result the following ruling was put in effect:

"Proprietary articles of merchandise, not in themselves unmailable, such as fancy soaps, tobacco, pills, tablets or other preparations such as are used by the medical and pharmaceutical professions, put up in fixed quantities by the manufacturer, for sale by himself and others, which may be sealed in such manner as to properly protect the articles, but to allow examination of such package in its simplest mercantile form, will be accepted for mailing; provided, that poisonous articles, or articles containing poison, and not unmailable, shall be accepted for mailing only when the package bears the label or superscription of the manufacturer of or dealer in the article mailed."

Under this ruling, it is possible to send any poison through the mail provided it is used by the medical and pharmaceutical profession and is put up by a physician or pharmacist in fixed quantities for sale by himself or others. It seems that it would be well to call the attention of the postoffice authorities to this matter and inform them it is the law in almost all states that poisonous remedies of the above character must be marked with poison labels indicating their dangerous character. Of course, it probably would be unjust to withdraw the privileges of the mail entirely from remedies of the above character, but the public ought to be protected in some way by suitable labeling at least.

"Skin-bleachers" have also received some consideration at our hands. The active constituents of these preparations consist for the most part of corrosive sublimate mixed with such articles as glycerin, tincture of benzoin and water. The effect of such a mixture is well known to all physicians. It is claimed by the promoters that they are able by the use of these mixtures to turn a black skin-white.

The colored race comes in for an additional "soaking" by firms who claim to make curly hair straight by ordinary ointments and oils.

OTHER FRAUDULENT REMEDIES.

One of the most interesting fraudulent remedies claiming to restore "lost vitality" is "Yousouf's celebrated Turkish salve," which an analysis showed to be nothing but a preparation of petroleum containing approximately 20 per cent. of beeswax.

The action of methylene blue is taken advantage of in many cases, and one firm claimed that if the patient would forward a colored "medicated cloth" (which proved on examination to be nothing but cheese cloth). after moistening the same with his urine, they would submit the colored cloth to an examination and report the nature of the disease to the patient.

INTERPRETATION OF THE LAW.

We wish to call attention to several different points that have been encountered and which at present can not be acted on, first, because of the marked division of opinion among the medical profession. and. second, because of the present construction placed on the law governing the use of the mails by the Department of Justice.

The first point is illustrated by a specific case involving a solution containing a very minute quantity of an organic copper salt, glycerin, phosphates, and, the manufacturer claimed, heroin, which could not be found. The greatest value of this remedy, it was claimed, resided in the very small percentage of copper it contained, which, it was held out by the manufacturer, was a remarkable cure for consumption. An investigation among the best medical authorities showed that they were all ignorant regarding the usefulness of an organic copper salt in the cure of this disease. Literature, however, showed that a number of remarkable cures had been effected by several French physicians, and there was nothing to do but to give the manufacturer the benefit of the doubt and permit him to continue his practice.

Attention is called to the fact that there are at present many remedies that are highly fraudulent and which are relieving the poor people of much of their hard-earned money. The concerns manufacturing these, however, can not be successfully attacked because they have transacted their business in such a way as to come within the rulings of the Department of Justice in the distribution of their remedies.

This ruling is somewhat as follows:

"The privilege of the mail can be withdrawn from parties only when they are using the mail for the distribution of their goods or the reception of money directly from their patients, or both."

There are many that are taking advantage of this situation, chief among which is that much-advertised and highly deceptive product known as "Liquozone."

It might be well to consider the desirability of placing these conditions before our legislators, but the chief difficulty is the point made by certain government officials that many of our senators and representatives are using remedies of this character in their own homes and believe that they have merits.

It would be a gracious thing on the part of the American Medical Association to encourage the Postmaster-General and the Secretary of Agriculture in prosecuting this line of work and to inform them of hearty support and the full co-operation of the Association.

It is difficult to say approximately what amount of money has been thrown into proper channels by withdrawing the privileges of the mails from many dishonorable concerns during the past two years. This, of course, has brought some ill feeling on the part of certain manufacturers who are recognized as of good standing, some of whom have come out and declared that these firms to whom they were supplying goods were legitimate and honorable. and that they could see no reason why they should be interfered with in any way.

THE INFLUENCE OF SACCHARIN ON THE DIGESTIVE ENZYMES.

S. A. MATHEWS and HUGH McGUIGAN.
CHICAGO.

Saccharin is of interest both from physiologic and economic points of view. Its extensive use as a sweetening agent in canned fruits and vegetables, in syrups, chewing gums, confections, etc., makes it of general dietetic importance. It is also a very common ingredient of lotions, especially of mouth washes. Its use in the diet of diabetics, where sugar can not be tolerated. gives it some importance in medical dietetics. The fact that the food laws of many states prohibit its indiscriminate use, and consider it more or less as a harmful adulterant, makes it incumbent on the pharmacologist to investigate its action on the body; the purpose of the investigation being to find out whether or not it exerts a deleterious influence.

CHEMISTRY AND PROPERTIES OF SACCHARIN.

Saccharin is the imido derivative of ortho-sulphobenzoic acid and is represented by the following formula:

$$C_6H_4<\begin{smallmatrix}SO_2\\CO\end{smallmatrix}>NH.$$

It dissolves with difficulty in cold water and slightly more in hot water. Its sodium salt is readily soluble in water at all temperatures. Saccharin possesses an extremely sweet taste, given usually at from 300 to 500 times as sweet as cane sugar. It is this characteristic sweet taste that makes its use so widespread. Most commercial manufacturers of the substance make much of this point in advertising their product.

For the detection of saccharin it is extracted with ether, or with a mixture of ether and light petroleum spirit. After evaporation of the solvent the intense sweet taste is characteristic. As a confirmatory test a part of the residue is treated with concentrated KOH or NaOH and the dish heated until the mass fuses and is maintained thus for about half an hour. By this means the saccharin is converted into salicylic acid. This can be recognized by its crystalline form, melting point and reaction with ferric chlorid. The reactions on fusing can be represented thus:

$$\text{I. } C_6H_4<\begin{smallmatrix}SO_2\\CO\end{smallmatrix}>NH+2H_2O\longrightarrow C_6H_4<\begin{smallmatrix}SO_2OH\\COOH\end{smallmatrix}+NH_3$$

$$\text{II. } C_6H_4\,(SO_3)\,COOH+2KOH\longrightarrow C_6H_4\,(OK)COOK+H_2SO_3+H_2O$$

On acidifying and extracting with ether, free salicylic acid is liberated from the salt. If salicylic acid is formed in this way outside the body, we thought there was a probability of its formation within the body. It is well known that many reactions which require high heat and the aid of strong acids or alkalies outside the body can take place readily when subjected to the energy of the body cells. On the other hand, benzol compounds in general leave the body in other well known forms. In our experiments, which are given below, we found that not a trace of salicylic acid was formed and that saccharin left the body entirely unchanged.

METHOD OF DETERMINING THE CONDITION IN WHICH SACCHARIN LEAVES THE BODY.

A solution of saccharin (garantose) was prepared by dissolving a known amount in water, by the aid of sodium carbonate. Just sufficient carbonate was used to dissolve the garantose and at the same time keep the reaction of the solution neutral, or very slightly alkaline. The solution was made to a known volume and injected slowly into the femoral vein of a dog. It was allowed to remain in the circulation from two to six hours, and then was washed out through the kidneys with a diuretic —M_8 Na_2 SO_4. The urine was collected from the ureters, and the amount of saccharin determined by converting it into salicylic acid. By this method we found that when we used from .25 grm. to .5 grm. garantose we could obtain 90 to 95 per cent. of the theoretical amount of salicylic acid in the urine. As commercial saccharin is not chemically pure it is necessary as a control to determine the amount of salicylic acid it will yield. The amount of the diuretic necessary to wash out all, or practically all of the saccharin can be approximately determined by taste. When about 150-200 cc. of the solution of urine and diuretic has been collected from the ureters, the fluid is practically all Na_2 So_4, and fails to give the test for saccharin. It is then made to a known volume and aliquot-portions used in the analysis.

ACTION ON THE BLOOD.

A neutral solution, prepared as above, and containing .25 grm. was injected into the femoral vein. After two hours some blood was withdrawn and its action on hydrogen peroxid tested. Normal blood from the same animal was used as a control. The results are as follows:

I.	II.
2 c.c. blood (sacch.)	2 c.c. Blood (normal).
10 c.c. water.	10 c.c. water.
2 c.c. H_2O_2.	2 c.c. H_2O_2.
Gas given off in 30 minutes:	
12 c.c.	13.5 c.c.
Gas in 2 hours:	
14 c.c.	14.0 c.c.

The only action here is a slight retardation of the oxidation.

In a second experiment normal blood was taken from the carotid artery and dry saccharin added to it.

I.	II.
2 c.c. blood.	2 c.c. blood.
0.1 gm. sacch.	3 c.c. H_2O_2.
3 c.c. H_2O_2.	
Gas in 10 minutes:	
18 c.c.	27 c.c.

Here the larger amount of saccharin causes a marked diminution in the oxidative power. On standing a longer time only a slight change was found in the relative and absolute volumes given in the table.

ACTION ON THE OXIDATION OF SUGAR IN THE BLOOD.

Every animal can oxidize a certain amount of a monosaccharid if it is injected directly into the circulation. The total amount that can be oxidized before sugar appears in the urine can be called the oxidizing coefficient of the animal. This amount will, of course, vary with different sugars, depending on the ease with which the sugar can be oxidized. In other work one of us (McGuigan) found that levulose is very much easier oxidized than any of the other common sugars. Consequently in this work we started with levulose. If the oxidizing power of the animal is lessened by the injection of saccharin—a fact which we have shown fully—then less sugar can be oxidized by an animal with saccharin in its blood than can be oxidized by a normal animal. To test this point we selected two dogs of about equal size and age. Dog 1 was used as a control. A solution containing 15 grms. levulose and 1 grm. sodium bicarbonate made to 500 cc., was injected into the femoral vein at the rate of 10 cc. every 5 minutes. Sugar commenced to appear in the urine when 250 cc. had run in. No sugar appeared before this time. The same strength of sugar solution with the addition of 2 grms. of garantose to 750 cc. of the solution, was run into the femoral vein of Dog 2 at the same rate as in Dog 1. Sugar appeared in the urine in this case when 140 cc. had been injected. If we assume that the dogs possessed the same oxidizing power, then clearly the addition of garantose materially lessens the oxidative power. This is corroborated by the rest of our work and is strikingly brought out by the work of Bornstein[1] We are aware that most diuretic salts and many anesthetics will produce a condition of glycosuria, and have been careful to avoid the use of such. In all this work chloretone was used as the anesthetic. In this last experiment no diuretic was used.

---

[1] Zeit. für klinische Medicin, vol. 40 p. 208. This reference also contains a résumé of the literature of the work on saccharin.

INFLUENCE OF SACCHARIN ON THE FERMENTATION OF SUGAR.

The urine containing levulose from the above experiments did not ferment with yeast. A solution of pure levulose was then tried and it fermented rapidly. If, however, a slight amount of saccharin was added, fermentation was entirely inhibited. Garantose is only slightly soluble in water; it is yet sufficiently soluble to prevent fermentation. This point is worthy of consideration in diabetic diets.

INFLUENCE ON THE WORKING OF SALIVA.

The influence of saccharin on the diastatic action of saliva is more pronounced than on any other enzyme of the body. Even traces exert an enormous retarding influence, while larger quantities *completely* arrest the action of the enzyme. This is shown by the following experiments:

	I	II	III	IV	V
Dry sacch. grms.	.2	.1	.05	.01	0
Saliva, c.c.	2	2	2	2	2
Starch paste, 2 per cent., c.c.	5	5	5	5	5

The solutions were mixed in vitro and placed in a thermostat at 40 degrees C. The results were as follows:

V—All digested in 8 minutes.
IV—All digested in 16 minutes.
III—All digested in 40 minutes.
II—Only trace digested in 360 minutes.
I—No digestion in 360 minutes.

The point when digestion was completed was indicated by the iodin test. No digestion was shown by failure to reduce Fehling's solution.

ACTION ON PEPTIC DIGESTION.

A 1 per cent. neutral solution of saccharin was prepared and the following experiments carried out:

	I	II	III	IV	V	VI
Pepsin, 2 per cent. acid reaction c.c.	4	4	4	4	4	4
Sacch. sol., c.c.	5	4	3	2	1	0
Water, c.c.	1	2	3	4	5	6
Fibrin, grms.	2	2	2	2	2	2

The above were shaken in test tubes and placed in the thermostat at 40 degrees. Results:

VI—All digested in 45 minutes.
V—All digested in 60 minutes.
IV—All digested in 85 minutes.
III—All digested in 100 minutes.
II—All digested in 130 minutes.
I—All digested in 350 minutes.

The retarding influence here is very apparent.

ACTION ON TRYPTIC DIGESTION.

Experiments were carried out with commercial pancreatin; *with fresh pancreatic extracts* and with pancreatic extract mixed with extract of the duodenum (dog). The proteolytic action of pancreatin and extract of the pancreas alone was only slightly affected by the addition of small amounts of saccharin. The diastatic action is materially decreased by the addition of saccharin, though not to so great an extent as the diastatic action of saliva. The most striking results are obtained when extract of the pancreas and duodenum are mixed.

An extract of the pancreas and duodenum of a dog was prepared by grinding the organs to a pulp and macerating 30 minutes with a 5 per cent. $Na_2 CO_3$ solution. The extract was then filtered and added to fibrin as follows:

	I	II	III	IV	V
Filtered ext., c.c.	5	5	5	5	5
Sacch. dry grms.	.1	.05	.02	.01	0
Fibrin, grms.	1	1	1	1	1

The mixtures were placed in the thermostat at 40 degrees C. and observed at short intervals, with results as follows:

V—All digested in 45 minutes.
IV—All digested in 105 minutes.
III—Almost digested in 270 minutes.
II—About half digested in 270 minutes.
I—Practically no digestion in 270 minutes.

No observations were made again for twelve hours, when the same condition was found as at the end of 270 minutes. These results indicate clearly enough the inhibitory action of the substance on pancreatic digestion.

ACTION ON THE OXIDATIVE POWERS OF MUSCLES AND GLANDS.

The muscular and glandular tissues of the body will all liberate oxygen from hydrogen peroxid. The amount of oxygen liberated by a given amount of the dried tissue is roughly proportional to its oxidative powers. If saccharin is added, the oxidation is lessened; if sufficiently large amounts are added, the oxidative power is entirely overcome. This influence is illustrated by the following experiments:

The tissues were prepared by grinding the fresh material to a fine pulp and macerating in 95 per cent. alcohol for 24 hours. It was then filtered, washed with alcohol and ether and dried in the air. After drying it was ground very fine and run through a fine sieve. The first experiment was with rabbit's muscle, 2 grms. in each:

	I	II	III	IV
Dry sacch., grams	.1	.05	.01	0
Water, c.c.	5	5	5	5
H_2O_2, c.c.	2	2	2	2
C.c. gas in 5 minutes	0	0	.8	2.5
C.c. gas in 10 minutes	0	0	1.5	3.4
C.c. gas in 30 minutes	0	0	2.0	5.5
C.c. gas in 60 minutes	0	0	2.2	5.8

In a second experiment rabbit's liver was prepared in the same way; using .2 gms. gave the following results:

	I	II	III	IV	V
Saccharin, grams	.2	.1	.05	.01	0
Water, c.c.	5	5	5	5	5
H_2O_2	2	2	2	2	2
Gas in 5 minutes	0	0	2	4.5	12.0
Gas in 10 minutes	0	1.5	3.0	6.0	15.0
Gas in 30 minutes	0	2.5	3.8	8.0	17.2
Gas in 45 minutes	2	2.6	4.8	9.6	18.0
Gas in 60 minutes	2	3.0	6.5	12.4	19.0

In Experiment 3, dog's muscle and liver were treated in the same manner, with the following results:

DOG'S LIVER, TWO-TENTHS GRAM IN EACH.

	I	II	III	IV
Sacch., grams	.1	.05	.01	0
Water, c.c.	5	5	5	5
H_2O_2, c.c.	2	2	2	2
Gas in 5 minutes	0	0	1.5	4.0
Gas in 10 minutes	0	0	2.3	5.5
Gas in 20 minutes	0	.5	4.0	8.5
Gas in 40 minutes	0	1.0	5.2	9.5
Gas in 60 minutes	0	1.8	6.8	9.6

DOG'S MUSCLE, TWO-TENTHS GRAM IN EACH.

	I	II	III	IV
Sacch., grams	.1	.05	.01	0
Water	5	5	5	5
H_2O_2	2	2	2	2
C.c. gas in 5 minutes	0	0	1	2
C.c. gas in 15 minutes	0	0	1.5	2.5
C.c. gas in 30 minutes	0	0	2.0	3.0
C.c. gas in 45 minutes	0	0	2.5	3.5

From these results it is evident that saccharin in small amounts retards oxidation, and in larger amounts prevents oxidation both in herbivorous and carnivorous animals. These results agree fully with those of Bornstein,[1] who found that the administration of saccharin caused an increased elimination of total nitrogen. The amount of nitrogen in the urine was less than before the using of saccharin, but the amount in the feces was greatly increased, so that the average of the two was greater than before using it. This means either a decreased hydrolysis or a decreased absorption of proteid, or both. As a matter of fact, Bornstein proved that absorption was materially lessened by the use of saccharin. He also observed that on those days in which he used it he suffered from headache and other symptoms of gastrointestinal derangement.

The experiments recorded above confirm the work of Reigler,[2] although it seems that we noted a more powerful action than that reported by him. This is undoubtedly due to the using of different brands of saccharin. In our work we used the "garantose" handled by Merck & Co. Reigler used that manufactured by Fahlberg, List & Co. The commercial products vary in strength, and to obtain uniform quantitative results a chemically pure preparation must be used.

PHARMACOLOGY OF SACCHARIN.

Saccharin is used in medicine solely on account of its sweetening properties. As we have shown, it has a retarding influence on the action of the digestive juices, especially that of the saliva and pancreas. Its prolonged use would, therefore, tend to produce digestive disorders. When injected into the circulation of an animal it produces depression and stupor, followed by labored respiration similar to asphyxia. This is evidently due to its inhibitory action on the enzymes in the blood and also in the tissues in general. This action very probably accounts for the headache and other symptoms which follow its use. Like many of the other benzol compounds, it may be considered a general protoplasmic poison, in that it inhibits nearly all the fermentative processes of the body. Consequently it interferes with and decreases the general body metabolism.

LEPROSY, BLASTOMYCOSIS, LUPUS, SYPHILIS, ALOPECIA AREATA, LUPOID SYCOSIS.*

JAMES NEVINS HYDE, M.D.
Professor of Diseases of the Skin, Rush Medical College.
CHICAGO.

LEPRA TUBEROSA.

Case 1.—J. G., male, aged 20, a native of Russia, came to this country six years ago, and has since that date lived in one of the western states contiguous to Illinois.

History.—Three years ago he began to suffer from a series of febrile attacks, accompanied by chills and by eruptive symptoms of an erythematous type, which were supposed to be syphilitic in character and for which he was subjected, without remedial results, to a course of specific treatment. Aside from the symptoms referred to, he has enjoyed fair health. There is no history of venereal disease; he has occasionally indulged in tobacco smoking; his family record is good. His father, who accompanies him, is a healthy-looking, though somewhat undersized, Polish Jew.

Examination.—The face of the patient is seen to be the seat of a diffuse infiltration, chiefly conspicuous about the nares, the brows, the lips, and the ears. The infiltrated area, though diffuse, is studded here and there with smaller and larger tubercles. There is marked alopecia of the brows. On the forearms, hands, legs, and the dorsum of the feet, there are larger and smaller poorly defined areas of punctate pigmentation; and here, as also where no such coloration exists, there are areas distinctly insensitive to hot and cold applications and to the prick of a pin. On the extensor surface of the left wrist is a large, coin-sized keloid developed from a burn which, he states, at the time of its infliction, produced no pain. The ulnar nerves are enlarged and somewhat corded, but the ascending great auricular nerve is not involved. This special nerve is said to be implicated in nearly 90 per cent. of similar cases, and its induration is readily demonstrated in the patient whom I shall next present to you. There is a deep, funnel-shaped ulcer in the sole of the left foot corresponding in character with the symptoms of *mal perforant du pied.* This young man has had frequent attacks of epistaxis. The mucous membrane of the nasal cavity is studded with small pin-head-sized and larger tubercles and irregular, shallow ulcers, thus explaining largely the catarrhal symptoms of which he complains.

This patient was first examined on Dec. 4, 1904, at which time a small nodule was excised for examination. The section when stained exhibited numerous lepra bacilli and the same micro-organisms were thickly dispersed in a smear of the nasal secretion.

Points of Special Interest.—Though presenting typical and unmistakable symptoms of tubercular leprosy, with an admixture of lesions commonly found in anesthetic types of that disease, this patient presents several points of special interest.

His youth and the relatively brief period of time during which he has suffered from the disease may be named first in order. These promised well if an appropriate therapy were instituted. He was placed on chaulmoogra oil, beginning with five minims in a glass of milk administered three times daily, the dose being progressively increased to nearly a teaspoonful. With this were administered ferruginous tonics; and a carefully directed hygiene was insured.

The results have surprised all who have watched the progress of the case. The general appearance and health of the patient have greatly improved. The skin is fairer, less muddy, less infiltrated. Over the brows the tubercles are now scarcely evident. The catarrhal symptoms are less severe. The only feature of his case in which there has not been corresponding improvement is the plantar ulcer. This we shall treat surgically.

Second: The origin of the disease. The youth almost certainly contracted leprosy in Russia. Instances of this malady, originating in the United States, are, indeed, few. My colleague, Dr. Ormsby, has reported one such case, the patient having been exhibited to this clinic last year. In his published report of this case, Dr. Ormsby makes reference to the case of the child of a leprous patient presented by me before this clinic several years ago, in which it seemed highly probable that the child, a native American, contracted the disease, presumably from the father, in the state of Nebraska.

Third: The demonstration of lepra bacilli in great numbers in the nasal secretion would seem to argue in favor of the opinion long sustained by Dr. Morrow, of New York, that most cases of leprosy are contracted by the medium of nasal secretions. It should be added, however, that in most of the leproseria visited by me the organs, apart from the skin and viscera, most frequently involved were without question the eyes. The number of blind lepers in any asylum devoted to this class of patients is pitifully large.

Case 2.—This patient, F. B., aged 27 years, a native of Australia, left his home seven years ago to become a sailor.

History.—In the course of his voyages he has visited Ceylon, India, Norway, Sweden, China, and the West Indies, and has lived an irregular sexual life in all these countries. At one time he was associated with a bunk-mate supposed to have the same disease and with whom he occasionally exchanged clothing. It appears, however, that before he left Australia an odd-looking "patch" appeared on his back, which may possibly have been the first symptoms of the disease with which he is now affected. There is a leper asylum in the vicinity of his native town. His history, prior to the development of the present disease, is not significant. His parents are healthy and free from symptoms of his ailment. The tip of the left index finger has been removed as the result of a traumatism. His functions are regularly performed.

Examination.—At the present time, the dorsum of the trunk is seen to be symmetrically, though irregularly, overspread with circular and ovoid patches having a faintly erythematous central area surrounded by annular bands from one to two centimeters in width, pigmented in yellowish-brown shades. There are about a score of these visible, varying in size from the section of a hen's egg to the palm of a hand; some of them are insensitive to both superficial irritation and to cold and heat. There are other areas of anesthesia where the pigmentation and color changes are absent, as, for example, about the popliteal spaces, but more particularly over the posterior aspect of each forearm from the elbow to the ulnar side of the hands as far as the digital borders. The anterior surfaces of the thighs and the left patellar region are equally insensitive. The nerve trunks in both arms are corded and tumid; the great auricular nerve (as explained in the case of the patient previously presented) is distinctly thickened and indurated. There are a few pea-sized nodules, subcutaneous in situation, discernible in the skin of the forehead. Here, however, as in the skin covering the temples, the ears, and the alæ of the nose, the integument is more or less evenly infiltrated. Making allowance for the characteristic color of the skin of the native Maori, the hue is of a deep mahogany shade and glistens as if artificially oiled. The expression of the countenance is characteristically dejected. The reflexes are exaggerated; the mucous membranes apparently are not involved.

---

[2] Archiv. für Exp. Path. u. Pharmacologie, vol. 35, p. 306.

* A clinical lecture delivered before the Visiting Alumni of Rush Medical College at the Commencement of 1905.

This leprous patient first applied for treatment at the clinic in February, 1903, and since then at regular intervals has been under our observation. Lepra bacilli were readily recognized in sections of tissue; the diagnosis was thus assured. His disorder is predominantly of the anesthetic type.

Treatment.—His improvement during the first year was pronounced and in a high degree satisfactory. The treatment pursued was largely hygienic and by the administration of tonics. For the last year, however, during which time he has been absent from the city, he has manifestly deteriorated in health. The leonine facies of lepra is becoming pronounced; he suffers from vague pains; is somewhat cachectic and has lost flesh. It is a source of regret that he was not placed at once on the chaulmoogra oil, which we purpose now to administer in the largest tolerated dose, as in the case of the patient last examined.[1]

BLASTOMYCOSIS.

CASE 3.—W. K., a Lithuanian, aged 34, male, laborer, weighing 160 pounds, married but childless, has a fairly good family history. Three brothers and one sister are living, in good health; two sisters are dead of some disease unknown.

History.—He has suffered for one year from a lesion somewhat below the left popliteal space. This lesion is an irregularly oval ulcer, 4½ by 2½ inches in dimensions, with its long axis at right angles to that of the limbs. This is a typical blastomycotic patch, the presence of innumerable blastomycetes having been demonstrated with the microscope. The organisms are now growing in cultures of several generations. As the peculiarities of these lesions have been made the subject of a vast amount of description and illustration, I shall content myself with pointing out the chief peculiarities here visible, merely adding that none of the pictorial representations of the disease as it affects the skin is more classical in its features than the patch now before you.

The surface is beset with irregularly massed verrucous and papilliform projections, uniformly elevated, and no part markedly projected above the general level of elevation. The edge of the patch is formed by a raised ridge, sloping gradually to the surrounding sound skin, the outer surface of this sloping border being thickly beset with exceedingly minute typical abscesses containing, when explored with due precautions, pure cultures of double contoured organisms, each having a central or laterally placed vacuole, and all showing budding outgrowths, the daughter organisms being both smaller than, and in cases as large as, the mother body. In general, the exposed surface is hemorrhagic, bleeds readily on gentle friction, and here and there is slightly crusted from desiccation of the purulent secretion it furnishes, though as the dressings have been removed prior to bringing the patient into the arena, the general aspect of the patch as we now see it is florid.

General Discussion of the Disease.—This disorder has been named the "Chicago disease," for the reason that more cases have been reported in this city than in any other of the world, though the first studies of the malady were made in patients observed by Busche and Buske in Germany and by Gilchrist in Baltimore. The scientific men of Chicago, and of other American cities as well, have diligently but vainly sought the reason for the enormous preponderance of the disease in this city.

One of the most significant and imperative of the questions which have arisen in this connection relates to the fatality which has of late befallen the victims in these Chicago cases, now numbering more than forty in this city alone. The first instance reported by us justified the name originally given to the disease by Gilchrist, of Baltimore, viz., "blastomycetic dermatitis." But the occurrence, under our observation, of cases in which not merely the skin, but also the viscera were involved, cases, in fact, in which the skin was secondarily attacked after organisms plainly had been demonstrated as of earlier origin in the liver, spleen, or kidneys, cases going on to a fatal termination, and in which, *even after a first cutaneous* expression of the malady, there was later systemic infection, revealed the subject in an entirely novel light. They presented for solution a new problem. Were these cases in any way related to those recognized by our colleagues in California and described by them under the titles, "protozoic infection," "coccidioidal infection," etc.? In all the California patients there had been a fatal issue; but the organisms in the human body in these sufferers never formed buds, but invariably reproduced by sporulation. We are now closely watching two subjects of the disease in whom there are symptoms pointing to a speedily fatal issue; one of these cases, for the first time in our experience, occurred in private practice.

The originally highly vaunted treatment of blastomycosis, by the administration of iodid of potassium internally, is without question of value. That this drug possesses an inhibitory influence on the evolution of the organism and at times completely suffices to destroy its activity can not be questioned. A few patients, without doubt, have been thus relieved. In many others, and in those cases resulting fatally, the medication has proved of temporary value only. In some of the fatal cases, intercurrent disorders, tuberculosis more particularly, has been responsible for the issue. The study of these phenomena is as yet in its infancy.

TWO CASES OF ERYTHEMATOUS LUPUS.

CASES 4 AND 5.—Of the two women now presented, one aged 35, is married and has suffered from a facial disease for two years; the other, unmarried, aged 29, has presented symptoms of the same affection for sixteen years.

Development of the Lesions.—In the first instance, the lesions have developed from a single patch on the left temple, which at first was a reddish disc, slightly elevated, scale-covered, and never discharging. Gradually over the bridge of the nose, the scalp, the cheeks, and in a less degree over the upper chest, similar roundish, flattened, scale-covered discs have developed. Those on the scalp have resulted in distinct depressions of the surface without complete loss of hair in the atrophic areas. In the case of the younger woman, similar roundish, scale-covered discs are exhibited over the face and also within the left ear between the tragus and the antitragus. A few smaller but similar discs are visible near the border of the scalp on the forehead. Both patients, treated by my associate, Dr. Quinn, have been greatly improved by radiotherapy and the use of the Pick jelly, which can be highly praised as a local application in the lesions of this character.

Remarks.—These are typical illustrations of erythematous lupus, a disease which has never yet been identified with tuberculosis of the skin, seeing that very rarely have tubercle bacilli been recognized in the tissue. Yet lupus erythematosus is a disease in which, as the French long have taught, curious, and in certain groups of observations, remarkably close relations are sustained by it toward tuberculosis. There are few clinicians of experience who have not seen generalized tuberculosis develop as a sequel of lupus erythematosus; and in other instances the two affections have unmistakably coexisted. In yet others absolutely no proof of tuberculosis of the skin or other organs can be adduced when lupus erythematosus has developed with classical symptoms. The common-sense view of these questions suggests that both in tuberculosis of the skin and in other conditions in which from any cause a diminution has been wrought in the resistance power of the economy, the skin undergoes this singular metamorphosis. Hutchinson and other English writers have laid stress on the fact of the frequency of these lesions in faces that have been much exposed to the weather; indeed, at times in those which have been wholly, or in part, frozen. Certainly it is significant that in most instances of the affection, first, the face, which is pre-eminently exposed to vicissitudes of the weather, is most often involved (cases of generalized erythematous lupus with grave symptoms are exceedingly rare); second, the face is affected rarely in infancy and childhood, but most often when the maturity of the body is nearly attained; in other words, when the face is, in its early experiences, most exposed to out-of-door accidents; third, women in slight preponderance with the delicate skin of the face unprotected by a beard, are somewhat more often disfigured in this way than men.

The old method of attempting to remove these patches by caustic treatment has been generally, though not wholly, abandoned. It has been asserted that radiotherapy, in these instances, is without value, but a great error is involved in such an assertion. Many of the discs wonderfully improve under judicious exposure to the *x*-rays; and in all cases a protective treatment accomplishes more in the way of cosmetic effects than any caustic method hitherto devised.

VERRUCÆ ACUMINATÆ OF THE ANUS.

CASE 6.—This lad, aged 15, has indurated and enlarged inguinal, postcervical, and epitrochlear glands, the relics of a fading syphilitic exanthem over the skin of his body, and gives a history of recent patches in the mouth.

Examination.—Two months ago he noticed a soreness about the anus, and then the lesions now exposed to view were recognized. These increased in size with great rapidity. When carefully inspected, it is seen that a group of venereal warts surrounds the verge of the anus, the entire mass being as large as a butternut, the individual warts being tufted, florid, secreting a thin, offensively smelling mucopus. As usual in similar instances, the warts are pointed, and in appearance resemble the comb of a cock.

I call special attention to the infundibuliform shape of this anus, the orifice of which, instead of being, as should be expected in so young a subject, neatly closed by the aid of the sphincter, is readily made sufficiently patent to admit a large thumb.

Remarks.—To the credit of the class of persons annually frequenting this clinic, it can be stated that this is one of the rarest of observations made in this ampitheater. I can not recall a similar instance in many years. The patency of the anus here is due to unnatural practices with a person of the same sex as the patient. The French, who have had a large experience of similar cases, call attention to this striking feature of the infundibuliform anus; and attention is directed to it here for the purpose of placing on guard every practitioner confronted with a similar case. Chancres of the anus are often, though not invariably, produced in the same way, exception being made in the case of women, in whom, on account of the anatomic features of the anogenital region, such an accident may result from venereal, though not from unnatural, practices.

Verrucous lesions of this sort, whether syphilitic or blennorrhagic in origin, it should be noted, are especially frequent in the very young. The vulva of a nurse girl, 16 years of age, lately examined here, was quite obscured to the view by similar growths. She had been infected on the finger by a syphilitic child for whom she had been caring. Venereal warts of the progenital region in both sexes, are, however, seen also in the third and fourth decade of life, but the larger growths, springing rapidly to full evolution, most often originate in the second decade of life, and in girls more often than in boys.

TWO CASES OF ALOPECIA AREATA.

CASES 7 AND 8.—These two patients, both male, both married, each 30 years of age, exhibit circular areas of baldness on the skin of the scalp, the patches being well defined, free from evidences of inflammation of every sort, and destitute of scales, crusts, or other evidences of disease, save that the scalp in the denuded areas is of an unduly whitened color. The patient on the left has noticed his disease for two months; the other, on the right, has suffered for four months. Each gives a similar history, first of a loss of hair over limited area not larger than a small coin; later there was an enlargement of the affected patch, and the appearance of new spots equally denuded in other regions of the scalp. These are typically evolved instances of alopecia areata, a disease as old as the time of Celsus, whose name was first associated with its lesions.

General Discussion of the Disease.—The valuable researches of Sabouraud respecting the bacterial origin of the malady, the unquestioned occurrence of small epidemics of the affection where the evidences of contagion have been apparently irrefutable, and the general suggestiveness of the appearance of the victim of the disease, have strongly influenced a large number of scientific men to ascribe to it a parasitic origin. The arguments cited on the other side, that, viz., in favor of the neurotic origin of the malady, are numerous and not to be ignored. First, no typical evolution of such patches in sound individuals has resulted from intentional inoculation of pure cultures of the micro-organisms asserted to be the effective cause of the disease. Lesions, it is true, have been thus produced; but these fall short of betraying classical symptoms of alopecia areata. Second, a fact abundantly demonstrated in scores of cases exhibited in this clinic during the last few years, traumatism of the skull (blows, falls, etc.), have repeatedly brought about these losses of hair; and the same may be said of intense nervous strain, domestic grief, and grave exhaustion of the nervous centers. One of our recent patients, a child, was shocked by a scream that brought on temporary unconsciousness, the hair falling typically in due time after; in yet another instance, a boy who had suffered from classical symptoms of alopecia areata suffered from a lightning stroke which left him insensible and, according to the statement of his attendant, "black in the face" for twenty minutes. He had prompt return of the hair after the effective shock of the nervous centers.

In most of the clinical cases seen here, whatever the origin, antiparasitic treatment with scrupulous attention to the hygiene productive of value to the nervous centers, in the most cases, has set aside the chief danger, that, viz., of complete and remediless loss of all the hairy filaments of the body. The larger number of such incoercible cases occurs in private practice, the fact being possibly due, in the well-to-do classes of society, to the greater frequency of the stress and strain of modern life in large cities. The most important point in the forecasting of the future in these subjects concerns the age of the patient. After the thirty-fifth year of life, severe baldness of this type may be remediless.

Locally, we employ brisk stimulation of the bald surface, and, when the areas are not too large, gradual application to each of iodized phenol, creosote, and remedies of that class, always limiting the area attacked at a sitting to a few centimeters. We also employ with advantage the Finsen light, applied over small areas in successive sittings, so as to produce a characteristic reaction, as in the local management of lupus vulgaris. In all cases in which it is not contraindicated, there should be brisk friction of the body surface daily, not neglecting the spine, after cool salt-water sponging; a tonic treatment, both dietetic and medicinal; and relief from nervous strain.

LUPOID SYCOSIS.

CASE 9.—This patient, male, a fish-packer, married, aged 41, without a history of significance in connection with his present disorder, has suffered for nine years from a disease of the region of the beard which during the time named has been at times better and worse. He uses tobacco in moderation, both by smoking and chewing. The disorder first affected the left side of the chin, from which point it gradually extended until at present the entire bearded region is involved. The subjective sensations are those of itching and burning.

Examination.—On close inspection, it is clear that a somewhat active inflammatory process concerns the upper lip and the chin, which are evenly and symmetrically involved in a reddish infiltration dotted with minute pustules, each of which is pierced by a hair shorn in the process of shaving so as to leave for inspection a blackish stump at the apex of each pustule. The redness is due in general to a perifollicular halo about each hair-pouch, the proximity of each to its neighbors producing the general appearance of redness of the involved area.

This is the common picture of sycosis vulgaris, the absence of trichophytosis being demonstrable even without aid of the microscope, by the absence of bald areas in the bearded region, whence hairs have fallen in most well-defined instances of true "barbers' itch;" by the absence of the characteristic "lumpiness" of the affection last named (a feature due to the ing together of follicles invaded by the large-spored ringworm); and also by the general smoothness and symmetry of the lesions invading the chin and lips, a feature rather common in the usual type of sycosis vulgaris, that due to coccogenous invasion of the hair follicles. To this extent the symptoms presented are sufficiently common.

When the cheeks of this patient are examined, the picture presented is wholly different; in fact, the inexpert might be led to suppose that the disease in these parts differs from that which is actively invading the central portions of the bearded face. Here on the cheeks the redness is less distinct, the pustules are few, the tissues otherwise altered. The skin is thrown up into unsightly ridges; and between these, without appearance of arrangement in order, are sunken valleys, these last suggesting to the eye that the skin here is atrophied. The irregularly corded, ridged, and furrowed condition of the cheeks is one which is as characteristic of what is termed lupoid sycosis as are the phenomena recognized in the lips and chin of the ordinary vulgaris type.

Nor is this all. One rarely sees a distinctly developed and obstinate sycosis of lupoid type (Unna's *ulerythema sycosiforme*) without noting that the eyelids, as here, are the seat of a folliculitis, the hairs of the lids, especially of the lower lids, projecting from pouches distinctly involved in the same process as that visible in the actively progressing disease of the bearded region. The eyes are encircled, thus, with pinkish-tinted rims, a feature at first sight suggesting that the patient has granular lids; the symptoms, however, differ *in toto* from those of chronic conjunctivitis. These male patients, red-eyed and red-bearded, with chronic inflammation besetting the periphery of their hair follicles, present a complexus of symptoms that are especially interesting.

General Discussion of the Disease.—Here are some of the questions that arise in this connection:

Why do young male adults with the common symptoms of staphylococcic infection of the skin of the face, usually acute in type and readily relieved by appropriate treatment, not slide into conditions of sycosis in which the microscope only reveals staphylococcic and streptococcic invasion of their follicles? Why do pustular dermatites of the bearded region not invite attacks of sycosis? Why do most patients with the ordinary forms of sycosis vulgaris escape such severe manifestations as those displayed in the case of the patient before us? It is not easy to make scientific responses.

In the case of lupoid sycosis various hypotheses have been framed to explain the conditions present. By some it has been assumed that the disorder is simply a variety of lupus erythematosus affecting the region of the beard. An objection to such an inference is the fact that not rarely this part of the face is actually invaded with the occurrence of patches which then are distinctly characteristic of lupus erythematosus, and not at all similar to those of lupoid sycosis. It has also been claimed that the malady is one *sui generis*. In a few instances coming under our observation we have discovered the presence of tubercle bacilli. I am of opinion that the disease, in some cases at least, is one of the rare manifestations of tuberculosis in the skin.

Treatment.—The therapy of the skin in these cases is one that taxes to the utmost. No means at our disposal compare in value with radiotherapy. We shall treat the active symptoms in this patient with the usual shaving, shampooing, and application of the Wilkinson salve, containing sulphur, tar and green soap, at first in the strength of one part to ten of a simple unguent; later, if productive of good results, with the ointment in full strength. It is always needful in these cases to set aside the results of a catarrh, the secretion from the nasal passages in many cases lighting the disease afresh in the upper lip, whence it spreads. Tobacco usage is always prohibited; cold sponging of the body is regularly practiced; and bichlorid lotions regularly employed before the application of the pastes to the surface; these latter being always kept in contact with the affected face by means of lint spread with the remedy to be applied and bandaged over the part until improvement is demonstrated.

CASES ILLUSTRATIVE OF SYPHILIS.

I show you four patients, each exhibiting a different phase of the evolution of syphilis.

Case 10.—Man, unmarried, aged 28, gives a history of a progenital sore a few weeks ago, the date being indeterminate.

Examination.—He now suffers from mucous patches of the mouth, general adenopathy, and a generalized papular exanthem, covering the entire body surface. The picture is one sufficiently common in all clinical experience. The absence of subjective sensations, the discrete papules of the kind described in the text-books as the "small papular syphiloderm" in groups, their distribution, color, and symmetry taken in connection with the non-cutaneous symptoms make the diagnosis relatively facile.

Appearance of Syphilitic Eruptions.—I call attention to the fact, not sufficiently emphasized, that by the color of an eruption alone, apart from other symptoms presented, it is not safe to distinguish the character of an exanthem. The color of a cutaneous eruption varies from hour to hour with the special condition of the patient; it is not the same in a brunette and a blonde; it is not equally tinted in the face, the lower extremity, and the anal region: it is unlike in the palm of an infant and over the buttocks of an aged man. When one hears it said that as soon as the color is seen the diagnosis became clear, a shadow of suspicion crosses the mind. Syphilis has been described as an "imitator" of other diseases; it would be, perhaps, nearer the truth to declare that many non-systemic affections of the skin resemble those induced by syphilis.

All said and done, however, taken in connection with the character of the lesions exhibited, the browns, the purples, and the deeper reddish hues—the combinations producing what has been described as the "color of raw ham"—are often conspicuously displayed in the skin lesions of lues.

Case 11.—The next patient, a man, aged 45, has suffered from this disease for six years; and his symptoms are widely different from those presented in the younger patient just examined.

Examination.—The left leg is the seat of a circular, well-defined, clean-cut ulcer, with sloughy floor and purulent secretion; while here and there over the lower limbs, deeply pigmented circular patches of gummatous infiltration are displayed chiefly over the left lower extremity.

Remarks.—Between these two patients there is scarcely a point of close resemblance. Only the comparison of observations collected by many men during many years of experience has taught us the varying shades and pictures of the malady in multiform expression, at different periods of its curious career.

Case 12.—A woman, married, aged 28, complains of eruptive symptoms involving the face and hands.

Examination.—Here are symmetrical groups of papules, which do not itch, which have never exuded a serous discharge, and which are chiefly annoying by reason of their unsightliness. They involve the left side of the face near the nose—a common site—and the palms of the hands, the groups rarely exceeding the size of a half-dollar. In places they are covered with a thin, brownish-tinted crust. This patient has been infected, presumably by her husband, some two or three years ago.

Remarks.—It is the practice in this clinic to refrain from asking married women whether they have or have not had syphilis. Their answers to such a question, for the most part, would be valueless. We must know more than they, after inspecting their objective symptoms and securing such tags and ends of a physical history as they can furnish. By far the larger number of them all are innocent of sexual wrong-doing and are the victims of the faithlessness of their husbands, or, what is too often the case, of the infection of the latter prior to marriage.

Case 13.—A woman, aged 35, presents still a different picture.

History.—The patient has been married 18 years, and gives the following history of her pregnancies: First, a living child, now 16 years of age; second, a miscarriage at the fourth month; third, a child, which died three hours after birth; fourth, a miscarriage, the period of pregnancy in which it occurred not stated. She is suffering from severe cephalalgia, with nocturnal aggravation, and exhibits a tibial node, due to gummatous osteoperiostitis productive of intense pain at night and interfering with her sleep.

Remarks.—This last patient illustrates the importance of securing in all suspicious cases a record of the issues of every pregnancy. Such a record not only throws light on the fact of infection, but often also points with definiteness to the approximate date of the accident. In the case of this patient, the first pregnancy resulting in the birth of a healthy child now living suggests that during the first period of her married life both she and her husband were free from this disorder. Then followed a suspicious miscarriage at the fourth month and the sequels of the pregnancies following point to infection occurring between the two first conceptions; that is, twelve years ago. The present condition of the patient can be sufficiently explained by assuming that syphilitic infection occurred at that time. The cephalic pains which she endures are possibly due to an endarteritis obliterans, not sufficient to produce the graver symptoms of nervous syphilis, but capable of engendering the cachexia from which she obviously suffers. They are a menace to her future if they be not relieved, for while the hemiplegias and tabetic phenomena of late syphilis are more common in men than in women it is not to be forgotten that women, though less frequently, do actually endure the same affliction.

General Discussion of This Disease.—Why is it that when the virulence of syphilis is most potent and energetic, that is, in its earlier periods, when its manifestations are commonly most abundant, active, and impressive, the menace to the health, especially in the item of involvement of bone, nervous tissue, and viscera, is less formidable than later in the career of both the disease and its subject? The answer, given by those who yet hold to the old doctrines formulated by Ricord, is practically derived from the schemes of railway travel. The train starts on a time schedule from the point of departure, and only arrives at the more distant stations when a given period of time has elapsed. The objection to such a scheme, though widely accepted in the past, is admitted even by the French writers who were obliged to coin such phrases as "galloping" and "precocious" for those instances of syphilis in which what should be "late" symptoms of the disease develop "early." The truth seems to be that it is when the system is most taxed in the careworn periods of life, when child bearing has pressed its heavy burden on the woman, often otherwise overwrought, when the worry, the care, the burden of poverty, and the stress of life begin to tell on the reserve force of the body, that the toxins of the disease become most dangerous, even though possibly less potent.

Metchnikoff is of the later school of investigators who think that they have discovered the effective germ of syphilis. Schaudinn's *Spirochæta pallida*, recognized in eight cases of syphilis in man and anthropoid apes, never in non-syphilitic subjects, stained both by the Giesma and the Marino method, is believed to be the parasite long sought. Its discovery in experiments conducted in the Pasteur Institute of Paris seems to lend support to the position. We can only at this time repeat with Lerrede: "The great question seems to make progress."

Special Article

IMMUNITY.

CHAPTER XXV.—CHOLERA.

Concluded from page 789.

Prophylaxis.

The rational prophylaxis, which was founded by Koch on a knowledge of the biologic characteristics of the comma bacillus, has proved of great efficiency. The essential points are the following: 1. Immediate bacteriologic examination of the stools in suspicious cases. 2. Absolute isolation of patients, in a hospital whenever possible. 3. Thorough disinfection of the stools, linen, room and all articles with which the patient has been in contact, including water-closets and privies. 4. Continued isolation during convalescence until the stools are free from vibrios. 5. Repeated bacteriologic examination of the stools of those who have been in contact with cholera patients until their freedom from vibrios is assured. 6. Frequent examination of the water supply at different po order to detect the occurrence of water infection. 7. I water infection exists, exclusion of the water from all d es-tic uses, and the institution of means to rid the water of infection. This may be done in the case of infected wells, but in the case of large systems reconstruction may be necessary for future protection. Water for household use should be boiled. Kolle compares the conditions in Germany and Russia during the epidemic of 1892-4. In Germany, where Koch's principles of prophylaxis were rigidly observed, about 10,000 cases occurred, 9,000 of which were confined to Hamburg, whereas in Russia, where precautions were not enforced strictly or generally, 800,000 cases developed during the same period.

Vaccination.

Protective inoculation has shown itself to be of distinct value for prophylaxis against cholera. Ferran, a Spaniard, first practiced vaccination on a large scale in 1884, although little definite knowledge of the value of the procedure resulted from his work. He is supposed to have used impure cultures. Haffkine introduced protective inoculation on a large scale in India, and up to 1895 had inoculated 40,000 persons. Following Pasteur's method with anthrax, he used two vaccines. Vaccine 1 was a culture which had been attenuated by prolonged growth at 39 C. Vaccine 2, which was administered five days later, was a virulent culture. The living organisms were used in both vaccines and the injections were given subcutaneously. The local and general symptoms were mild. Instead of living cultures Kolle has proposed the use of virulent cultures which have been killed by exposure to a temperature of 58 C. for one hour. The vaccine is preserved by the addition of 0.5 per cent. phenol. In the Japanese epidemic of 1902 this method was used on an extensive scale. The incidence of disease among the uninoculated was 13 per cent., among the inoculated 0.06 per cent.; the mortality among the uninoculated was 10 per cent., among the inoculated only 0.02 per cent. The disease, when it occurred in the inoculated, was of a mild type. A single injection of from 2 to 4 mg. of a killed agar growth was given subcutaneously (cited by Kolle). Strong has proposed the use of the products of autolysis of the cholera vibrio as a vaccinating substance, a method founded on the observations of Neisser and Shiga in relation to typhoid, and of Conradi and Drigalski in relation to dysentery. The local and general symptoms are said to be of a mild type. The method has had no practical application.

Natural Immunity.

From what was said above in connection with the so-called cholera carriers, it is evident that not all are equally susceptible to infection with cholera. The conditions on which such cases of individual immunity depend are not known conclusively, although it is often intimated in a general way that a strong bactericidal power of the body fluids, or a high phagocytic power on the part of the leucocytes, is responsible for it. The gastric juice, on account of its acidity, offers a barrier to the passage of living vibrios into the small intestines. It is nevertheless evident that the barrier in many instances is not a serious one. Organisms which are ingested with water may pass rapidly to the intestines without being affected by the acid of the stomach, or when taken with food they may be buried in the latter and hence not come in contact with the gastric secretion. It seems probable that the intestinal epithelium has a certain resistance to invasion which is most manifest in the case of those who do not become infected in spite of the presence of the organisms in their intestines. Natural immunity is said, by Germans, to be one which is directed against the bacteria rather than against the endotoxin. Proliferation of the organisms in the intestinal epithelium is thereby prevented. Poorly nourished individuals, the very young and the very old are particularly susceptible. Other gastrointestinal disorders, in the presence of an epidemic, predispose to infection. Defects in the intestinal epithelium, or a decreased resistance of the latter, may afford conditions which are favorable for invasion.

Active immunity, as that which results from infection or from protective inoculation, is characterized by the appearance

Acquired Immunity.

of bactericidal amboceptors, agglutinins and specific precipitins in the serum. It is now widely believed that acquired immunity depends on the presence of the bactericidal amboceptors in the circulation and body fluids, although Metchnikoff holds, on the other hand, that it depends to a large degree on an increase phagocytic power on the part of the leucocytes. According to Pfeiffer and Marx, the antibodies are produced in the blood-forming organs. An attack of cholera confers immunity of prolonged duration, although it is not always absolute.

Passive immunity is readily induced in animals by the injection of anticholera serum. As in other instances, it is of short duration, however. Doubtless the same condition may be induced in man. Besredka has proposed mixed active and passive immunization by way of protective inoculation, using killed bacteria which have been saturated with the specific amboceptors.

Serum Therapy and Agglutination.

Serum therapy has been no more successful in cholera than in typhoid fever. The antitoxic serum of Roux and others has had no practical trial. According to Achard and Bensaude, the serum of cholera patients, on the third or fourth day of the disease, agglutinates the cholera vibrio. However, they used the serum in dilutions of 1-20, and in this strength even normal human serum may be agglutinating (Pfeiffer and Kolle, cited by Paltauf). Convalescents even after seven months may show an agglutinating power of from 1/100 to 1/120.

The bacteriologic examination of the stools is the most reliable means of early diagnosis (see above).

Clinical Reports

ERYTHEMA MULTIFORME FOLLOWING VACCINATION.

LOUIS M. WARFIELD, M.D.,

ST. LOUIS.

Considering the great number of persons vaccinated, the comparatively few complicating eruptions that occur is not a little surprising. As has been often remarked, many eruptions occurring in the course of a vaccination period are undoubtedly accidental, while others are undoubtedly due to the vaccine virus.

A condition sufficiently interesting to report came under my notice not long ago.

Patient.—Miss J. H., aged 23, a trained nurse, had never been vaccinated previously, and has always enjoyed exceptional health. Her appetite and digestion are good and menstruation regular. She had had the usual mild children's diseases when young, but had never had any eruptions. For about a year she has been very slightly troubled with constipation. Previous to her vaccination she had been in perfect health and had no gastrointestinal disturbance nor any symptoms of even a mild illness.

Vaccination and Result.—She was vaccinated July 29 on the upper left arm. On August 1, before she noticed anything at the site of the vaccinated area more than a slight itching, she saw irregularly shaped bright red spots on the forearm. These spots soon appeared on the lower legs, and shortly both arms from shoulder to wrist, and both legs from thigh to ankle, were thickly covered. These spots soon became firm, nodular and painful. There was no itching or burning. She felt sore all over. There were pains in the knee joints, and wherever the lesions were close to the bones they were very painful to the touch.

Examination.—August 4. She is a well-developed, well-nourished woman. The mucous membranes were a good color, tongue somewhat coated, pulse slightly accelerated, temperature 100 F. Over the extensor surfaces of the arms and legs there was an eruption consisting of rose-red irregularly-sized and shaped spots, level with the surface of the skin, bright red, somewhat infiltrated areas, varying in size from that of dimes to five cent pieces, and firm, deeply seated nodules, perceptibly raised above the surface of the skin. There were no vesicles, nor was there umbilication of the nodules. The nodules situated over bony prominences were quite firm and exquisitely painful to the touch. Some were of a typical violaceous hue and appeared shiny. There was no definite line of demarkation seen between the lesions and the surrounding skin.

Subsequent History.—New crops came out, following the order of ripening described from day to day, until August 8. In the meantime, the older lesions grew softer, less painful and more purplish in color. On August 8 vesicles appeared at the site of the vaccination. These ran a normal course. On August 10, three small vesicles appeared on the right forearm; by the next day these had disappeared, leaving small red spots with slightly umbilicated centers. By August 14 the rash had entirely disappeared and only a few brownish stains were visible. During the period of the eruption there was slight fever but not more than could be attributed to the effects of the vaccine itself. The only inconvenience was the general soreness, especially in the knees and elbows.

Remarks.—That this was a typical case of erythema multiforme is certain. The whole course of the eruption was short, but the lesions and their appearance in crops were typical. Most curious were the great tenderness of the nodules and the feeling of soreness over the arms and legs, especially around the knee and elbow joints. There were no lesions on the backs of the hands or dorsal parts of the feet. As usual with erythema multiforme, the eruption showed itself before the vesiculation of the vaccinated area.

LAPAROTOMY UNDER LOCAL ANESTHESIA ON A PATIENT, AGED SEVENTY-TWO.

R. L. IGEL, M.D.

LEAVENWORTH, KAN.

I wish to report a very interesting case that came under my care July 31, 1905.

Patient.—A woman, aged 72, was suffering from an ovarian cyst of seven years' standing, which had grown to such an extent as to fill the whole abdominal cavity.

Examination.—I found her in terrible pain, resembling that of obstruction of the bowels. An enema was given, with no results, and I knew that cathartics would only increase the trouble. I therefore determined to relieve the bowel that I was sure was being obstructed from the pressure of the cyst by tapping the tumor.

Operation.—She was taken to the hospital, a few blocks from her home and was prepared for operation. Chloroform and ether were contraindicated by her age and exhausted condition, so I began by injecting a small amount of a 4 per cent. solution of cocain three inches below the umbilicus, in the median line, just under the skin, and followed with my knife, making a clean incision. The adipose tissue was then gone through and separated until the peritoneum was reached, and this tissue was cocainized in like manner in front of the knife. This incision brought the cyst into plain view. I then tapped it with a small needle, to allow shrinkage enough to grasp the walls with forceps, after which a trocar was inserted and the liquid, which measured four gallons, was allowed to run off slowly. I made a complete exploration of the abdomen and of the adhesions and withdrew as much as possible of the cyst from the walls of the abdomen, so as not to allow of any infection, washed the sac out with normal salt solution, replaced it and allowed one-half pint of the solution to remain. I also filled the abdomen with normal salt solution and did as thoroughly aseptic an operation as possible. The peritoneum was closed with four stitches and the abdominal wall with two stitches. The patient talked to me in the meantime and turned herself on one side to help me drain the cyst. Her pulse and heart were constantly watched and she was allowed to take continuous sips of cool water.

Result.—She was removed from the table to a ward. She did not complain during the operation, nor since. The bowels moved freely of themselves. That night she took two cups of tea and slept the whole night, and has been doing well ever since. She experienced no shock whatever.

Remarks.—I did not allow any stimulants, such as strychnin or brandy, to be used. Morphia gr. 1/4, atropin gr. 1/150 was given at the start. I entered the abdominal cavity with the intention of giving my patient every possible chance, as I did not wish to infect the abdomen with a probable infectious tumor and, therefore, to endanger her life. As a general anesthetic was contraindicated it was necessary to use local anesthesia, but, in all, probably not more than 40 minims of a 4 per cent. solution of cocain was used.

The case appeals to me, for the case in which the abdomen was entered, the absence of bad after-effect and of shock, the entire absence of any discomfort from the operation, and the wonderful manner in which the patient is continuing to recover.

A FATAL CASE OF TETANUS OCCURRING WITHIN SEVENTY-TWO HOURS OF INJURY.

J. B. TYRRELL, M.D., Sc.M.
WATERVILLE, MINN.

Patient.—W. D. G., boy, aged 10.

History.—On Tuesday, Aug. 15, 1905, at about 6 p. m., the boy fell from a stageing to the ground, a distance of about 8 or 10 feet, and sustained a compound fracture transversely through the lower epiphysis of the tibia, the bone ripping the soft parts and stocking for a distance of 4 inches above the site of the fracture and sticking to the ground.

Treatment.—He was picked up and carried to his home, where the wound was cleansed thoroughly, care being taken to leave no foreign particles in it; hydrogen peroxid was used finally. The bone was replaced and the leg put in a temporary splint dressing. The subsequent treatment consisted of irrigation of the open wound and the liberal use of hydrogen peroxid.

Subsequent History.—On Saturday, August 19, his father, who is a physician, told me the boy had had during the previous night what appeared to him as premonitory twitchings, and on that day, Saturday, there was slight rigidity of the muscles of the neck and inability to open the mouth wide. Antitetanic serum was ordered for him. Intraneural and intraspinal injections were advised, but were refused. The serum was given subcutaneously, and the paroxysms were controlled by hypodermics of morphin every few hours. His symptoms progressed rapidly, and death occurred at 2 p. m. Aug. 23, 1905.

Remarks.—There is a question in my mind as to the time of inoculation in this case. Was he infected at the time of this injury or at an earlier period? About a week or ten days previous to this injury, according to the boy's mother, he stepped on a rusty nail, running it into his foot. The boy did *not* let his father know of this, and had his mother dress the wound, which healed promptly. He received this wound in practically the same locality in which the leg was fractured—not over 50 feet away. Was he infected with the tetanus bacillus at this time? I think it is possible, but I believe it is not probable in this case.

New Instrument

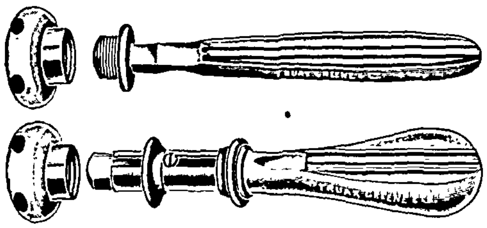
MURPHY BUTTON OBTURATOR AND APPLICATOR.

A. H. CORDIER, M.D.,
KANSAS CITY, MO.

Having used the Murphy button for many years and having met some difficulties in its application or introduction I have devised an instrument that in a great measure overcomes all the obstacles thus far met. The method usually employed heretofore to introduce the button has been to seize the rim of either half of the button with a pair of hemostats, thus forming a handle to facilitate the introduction.

On several occasions, not only in my own work but in the work of other surgeons, the grasp of the forceps has injured the thread of the button or has dented the circumference of one-half the button so that when the two halves have been applied and were ready to be shoved together they would not fit thus necessitating the removal of the second half of the button and the introduction of a new button in the place of the one injured by the forceps. One blade of the forceps must of necessity clasp the outer side of the stem of the button so that the purse string suture is tied over the end of the forceps, thus interfering with the proper adjustment of this suture, so that when the forceps were removed the button would drop into the intestine.

Again, while the button is being introduced the gases and other contents of the intestine are escaping thus increasing the dangers of an infection in the field of the operation. Frequently in tying the purse string around the stem of the button the mucous membrane would be crowded beyond the end of the stem so that when the approximation of the two halves was attempted this mucous membrane was found to be in the way. The forceps do not give a sufficiently firm handle to force the button into the viscera, and to overcome the objections met with in the application of the button, I have devised an instrument to be called the Murphy button obturator and applicator. This instrument is very simple in its use and facilitates very materially the introduction of the button. It requires three sets for the three sizes of the Murphy button. The obturator that is used in the female half of the button is simply a handle with the flange projecting where it comes in contact with the end of the stem, the portion projecting into the button is threaded to screw into the stem of the button, thus the opening in the button is effectually closed during its introduction; there is a good firm handle to hold to and the projection rim prevents the puckering string from crowding mucous membrane beyond the stem of the button.



The obturator that is used in the other half of the button is composed of a hollow canula with a movable center piece. This piece at the end that is introduced in the button is wedged shape so that when the projecting portion of the canula is introduced into the half of the button and the movable piece is pulled on it spreads the slit end of the canula thus holding the button firmly. After the two halves have been introduced and are ready to be pushed together all that is necessary is to unscrew the obturator in the female part of the button and to press on the handle of the movable piece in the canula, instantly releasing the hold on the male half of the button.

The application of this instrument is far more simple than this description would seemingly imply. A reference to the accompanying illustration will give the reader a better idea of the obturator and applicator than the description.

Overlying an Infant Punished as Manslaughter in England.—Thousands of cases of death from overlying take place in Great Britain during a year. In certain cases coroners have often wished to obtain a verdict of manslaughter against the mother, but public opinion is opposed to such a course. Even in cases in which the coroner's jury has brought in this verdict it is usually set aside by the grand jury finding "no true bill." A case has at last occurred, however, in which the mother has been punished. At the *Chester assizes* Judge Phillmore sentenced a woman aged 31 years to twenty-one months' imprisonment with hard labor. Eleven days after confinement she took her child to bed with her while in a drunken state. She slept heavily and overlay and suffocated the infant. The jury found her guilty of manslaughter by an act of gross and culpable neglect.

SATURDAY, SEPTEMBER 16, 1905.

THE TECHNIC OF PERCUSSION.

One of the first things taught to students of medicine in the clinical course is the art of percussion. Along with inspection, palpation and auscultation, percussion is a fundamental method of examination. Unfortunately, it is too often improperly taught, and even when the teaching is good it is surprising to find how few students perfect themselves in its application. Since the advent of laboratory methods, too, it is to be feared that less attention is paid to physical methods than is their due. Microscopic examinations of sputum and blood are extremely helpful, but the physician who relies on such methods alone and who does not practice assiduously the time-honored physical methods will make but a sorry mess of his work.

It matters but little which method of indirect percussion one uses—finger on finger, finger on plessimeter, or hammer on plessimeter; the important matter is to learn thoroughly one of the methods or all of them, so as to obtain trustworthy results. The percussion by finger on finger, however, has many advantages. In the first place, one has his armamentarium always with him, while hammer and plessimeter are constantly being left behind, lost, or broken. In the second place, the sound yielded by the finger itself is less disturbing than that of the plessimeter. In the third place, the sensations of touch and resistance felt by the finger percussed are often as important as the percussion sound, and they are missed when hammer and plessimeter are used. Finally, one can control the pressure of the finger against the surface to be percussed more easily than that of the plessimeter, and this is of as great importance in eliciting distinctions of percussion-sound as is the force of the blow of the percussing finger itself. It is easier at first, it is true, to secure fairly satisfactory results with hammer and plessimeter. Percussion by finger on finger is undoubtedly harder to learn, but once skill is acquired the method for most purposes is superior to all others.

Like every art, percussion can be perfectly learned only by long experience. There are, however, a number of small details of technic which, if observed, help greatly in the acquisition of the art. The error made by all students at the beginning (and it is to be feared by many teachers in the so-called percussion courses) is an attempt to produce loud sounds, sounds that convince the neighborhood. Nothing could be more disastrous to success. Even when it is desired to elicit the so-called "deep dullness" in contradistinction to "superficial dullness," a very slight blow is required, only a little stronger than the delicate stroke needed to demonstrate the latter. The clinician who percusses so that an audience in an amphitheater hears the sound undoubtedly makes a noise, but nothing accurate in the way of percussion limits can be so demonstrated. When the superficial dullness of the heart, for example, is to be outlined on the thoracic wall, the lightest possible percussion should be used. The moment one percusses strongly the vibration is propagated beyond the local limits and a mixed sound is produced. Indeed, the skilled diagnostician in localizing superficial limits on the thorax percusses so lightly that over an area of superficial dullness practically no sound is heard; then the moment he moves from the solid organ to an air-containing one the same percussion stroke produces a distinct resonance. In no other way, to cite another example, can the so-called "lung-liver limit" be accurately localized. With the light percussion described—so-called "superficial percussion"—the areas of solid organs on the thoracic wall can be demonstrated with ease, and small pleuritic effusions, pneumonic patches, or pulmonary infarcts which on ordinary rough-and-ready percussion would be entirely overlooked are readily localized. The accurate determination of the deeper dullness, for example, the deep cardiac dullness (so-called relative dullness) is far more difficult than the determination of superficial dullnesses; but here too the rule is to use the lightest percussion stroke that will elicit the distinctions which exist. In determining superficial dullness, the plessimeter finger should be applied as lightly and evenly as possible, without pressure, to the surface to be percussed; in eliciting deeper dullness the plessimeter finger may be more firmly applied.

In this indirect percussion only one finger of each body surface, a point of great importance in the production hand for making the blow, the index, or preferably, the middle finger of the left hand for receiving it (plessimeter finger). The plessimeter finger, with volar surface applied to the part to be percussed, must be everywhere in close contact with the surface and should be placed parallel to the boundary line which one desires to determine. The percussing finger (its nail closely pared) is flexed and the blow so given that the axis of the terminal phalanx, when the pulp of the finger strikes the plessimeter finger, is perpendicular to the body surface, a point of great importance in the production of the right sounds. The hand and fingers should be held loosely, anything like an awkward, tense or cramped attitude being avoided. The blow is made solely by flexion of the wrist, the forearm remaining stationary; it should be light, as has been said, short and elastic.

If medical students could be carefully supervised until they have acquired the technic of percussion and have learned to have real confidence in the results obtainable by it, instead of being compelled, as they often are, to carry into their practice that distrust which is engendered by false methods and insufficient training, the art would be far more highly valued and more widely practiced than it is even to-day. Fortunately, exact training in the method of percussion is now being insisted on in our best medical schools; moreover, those of us who failed to get it may easily acquire a good method if we patiently set about it with the aid of one of the many good text-books now available.

REGIONAL DISEASES AND THE SESSIONS OF THE AMERICAN MEDICAL ASSOCIATION.

When medical associations were first formed in this country one of their principal avowed objects was the gathering of data in order to enable physicians to understand the various diseases which occurred in different parts of the country. At that time, over a century ago now, meteorologic conditions were considered to influence disease types, much more than is now known to be the case. In spite of this, however, there is a very interesting variation in disease in different parts of the country, and the annual sessions of the American Medical Association—held each year in a different section—serve to call special attention to this. When the Association met at New Orleans two years ago, special attention was given to the intestinal parasitic diseases of the southern states, and great light was thrown on the practical side of the diagnosis and treatment of these affections.

The recent session in Portland, Oregon, has enabled us to add to our knowledge of types of disease which exist on our western coast. It was interesting to find that practitioners along the Pacific coast are universally agreed that the various forms of vascular degeneration are more common in the far western states than in other parts of the country or in Europe. From San Francisco, particularly, it was reported that precocious arteriosclerosis is a rather common affection. This is true not only as regards the ordinary thickening of arteries, but also of the occurrence of the advanced stages of arterial degeneration as represented by aneurismal dilatation of various arteries. Aortic aneurisms are particularly common, considering their rarity ordinarily, and are found to affect not only the arch of the aorta, but also the abdominal aorta. There is no doubt about the diagnosis of these cases, for quite apart from the fact that the diagnosis was made by careful, conservative clinical observers it was confirmed in most cases by means of the x-rays, and under ordinary circumstances this leaves very little room for doubt in these conditions. A report of undue frequency of premature arterial degeneration on the Pacific coast would have caused little surprise had it been made thirty years ago. At that time the pioneers of the early days in San Francisco, the forty-niners and men of the early fifties, were still alive. These men presented in their life histories most of the etiologic conditions which are usually considered to bring about arterial degeneration. Most of them had been very hard workers and had gone through serious privations in the pioneer days. Nearly all, under the trying circumstances of their lives, had used alcohol to excess, and not infrequently with an irregularity of food consumption and a lack of nutritious material likely to make alcohol even more serious in its effects than usual. Not a few of them indulged in other vices and suffered the usual effects which were much more liable to occur under the low moral conditions of the early days.

In addition to the above diseases, many affections of the thyroid gland are reported[1] as existing quite commonly, not only along the southern Pacific coast in California, but also in the Pacific northwest. It is reported that a certain number of animals with enlarged thyroids have been observed in Oregon and in the southern part of Washington. Ordinary exophthalmic goiter occurs apparently with more frequency in and around San Francisco than in the large cities in other parts of the country. It would seem not unlikely that if these two conditions of arterial degeneration and thyroidism really exist they may possibly be connected with one another. The over-action of the heart so common in exophthalmic goiter may very well be the cause of the arterial degeneration seen in other cases. It is possible that while other symptoms are only slightly manifest the effect on the heart may be very marked and this in turn may cause the over function of the arteries which ultimately leads to sclerotic conditions. It is to be hoped that the attention which has been directed to the diseases of the Pacific coast may result in new light being thrown on the etiology of these important conditions.

THE EFFECT OF TOBACCO IN HEALTH AND DISEASE.

Next to alcohol, there is probably no substance used by man which has been so villified and condemned as tobacco. Certain intemperate temperance advocates from time to time have attempted to pass laws prohibiting the use of certain forms of the weed in various states, and in some instances anticigarette ordinances have been placed on the statute books. Probably the smokers in such states believe themselves much persecuted, when, as a matter of fact, there were at one time European countries in which smoking was illegal, and in Turkey the offence was, for a short period, punishable by death.

The attitude of certain in authority regarding the practice of smoking during the early days of the habit is shown by the words of James I. of England, expressed in his celebrated "Counterblaste to Tobacco." He describes smoking as "a custom loathsome to the eye, hateful to the nose, harmful to the brain, dangerous to the lungs, and in the stinking black fumes thereof nearest resembling the horrible Stygian smoke of the pit that is bottomless." It can not be denied that in modern times large numbers of medical men have been addicted to the use of tobacco, perhaps a larger percentage than of men in general. The consumption of this substance in its various forms reaches an enormous figure each year, and one is tempted to ask, If it is so harmful, why do not physicians see more of its ill effects? As a matter of fact, there is singularly little literature of a convincing nature bearing on its evil effects, if we except one or two conditions like the tobacco heart and tobacco amblyopia.

---

[1] Herbert C. Moffitt: "Affections of the Thyroid in California," The Journal A. M. A., this issue, p. 837.

A perusal of a series of papers concerning the effect of tobacco in health and disease, contributed by a number of eminent English authorities,[1] leaves one with the feeling that there is still much to learn regarding this substance. The evidence brought forward as to its action on the various organs seems to bring out sharply a few facts, the most important of which is that tobacco is undoubtedly injurious during childhood and youth. The evidence that it is to any great degree injurious to the mature adult is much less strong. There is, on the other hand, much evidence to indicate the stimulating and sedative effect of smoking in moderation. Lauder Brunton, who deals with the action of tobacco on the circulation, cites cardiac irregularity as the common symptom of excess, and pseudoangina as the rare one. The contributor on the effects on the gastrointestinal tract, Dr. Norman Dalton, is able to find but one or two cases in the literature in which a convincing relation between tobacco and stomach trouble exists. It is admitted that we know but little about the effect of tobacco on the intestines, though there is clinical experience, opposed to experimental data, that it favors peristalsis. The effects of tobacco in excess on the nervous system are tremor, giddiness, vasomotor disturbances, such as cold hands and feet, and intranocturnal insomnia.

The effects on the mouth and tongue may be said to be, in the main, minor, though the predisposition to epithelioma of this region must not be overlooked. The effect on the upper air passages is to produce in some cases a pharyngitis and to exaggerate already existing pathologic conditions, such as sinus disease. The general impression gathered from these papers is that in the adult tobacco must be used to excess to produce serious consequences; that even under such conditions severe lesions are rare; that cigarettes are the worst form in which to use the substance, and that the poisonous effects of tobacco are greatly increased by the simultaneous use of alcohol. The question simmers down, then, to the old one of moderation, except in the case of individuals with an idiosyncrasy to the weed. Just what is moderation must, of course, be decided in each individual case by actual experiment. One man can consume with impunity a number of cigars or cigarettes which would seriously poison another. The whole subject is one which needs further investigation, and which will be most difficult to elucidate, at any rate clinically, on account of the frequency of complicating conditions, such as the simultaneous use of alcohol. In view of the scantiness of the literature on certain phases of the subject, it is to be hoped that the profession will be on the lookout for cases of this character and will record them.

THE OXIDIZING FERMENTS OR OXYDASES.

In a recent issue we called attention to the catalytic nature of the intracellular ferments and referred more particularly to the work which has been done on the enzymes which accelerate proteolysis and autolysis. Just as interesting are the researches of ferment chemists concerning the influence of enzymes on the processes of oxidation which go on in living organisms. Since Lavoisier's time it has been known that the animal body possesses oxidizing properties; later studies went far toward localizing the oxidation processes in the cells (Hoppe-Seyler, Pflüger, Schmiedeberg); still later it was proved that the cells need not be intact to cause the oxidation, crushed cells and cell extracts being shown to be effective; finally, it has been demonstrated that the oxidizing processes in the cells are dependent on the presence in them of specific catalytic agents—the oxidizing enzymes or oxydases (Bertrand, Schoenbein, Jacquet, Schmiedeberg, Jacoby). A whole series of oxydases is now recognized, but we shall refer only to six better known examples.

First of all there is the ferment which oxidizes hydrogen peroxid to water and free oxygen gas. It is a matter of every-day experience that oxygen gas is liberated when hydrogen peroxid solutions are brought into contact with blood, pus or tissue cells. The proof has been definitely brought that this oxidation is due to a special enzyme, which is destroyed at a temperature of 100° C., and whose action is inhibited by poisons like hydrocyanic acid. This ferment is widely distributed in the body, the scale of activity, according to Spitzer,[1] decreasing in the series—blood, spleen, liver, pancreas, thymus, brain, muscles, ovary, Fallopian tube. A second oxidizing ferment is that in animal and plant cells which turns the guaiaconic acid of gum guaiacum blue. It also is inhibited in its action by hydrocyanic acid (Schoenbein).

Closely allied to the above is the third very important oxidizing ferment, the so-called laccase of Bertrand.[2] It was shown by Yoshida that this enzyme is responsible for the formation of that valuable commercial product, black Japanese lacquer. Bertrand has made a thorough chemical examination of laccase. He obtained it in preparations free from albumin and demonstrated in it the presence of manganese, along with non-nitrogenous organic substances. This finding is of great importance, for it suggests the possibility that the nature of ferments is to be sought in combinations—probably colloidal—of organic substances with metal ions.

Remarkable in its oxidizing effects is a fourth enzyme, the so-called tyrosinase, discovered by Bertrand.

---

[1] Pflüger's Arch., vol. lxxvii, 1897.

[2] Compt. rend. de l'acad., 1895-1897.

He found it in plants and showed that under its influence the white amino-acid tyrosin is converted into colored compounds. One sample of tyrosinase obtained by Gonnermann[3] is capable of changing tyrosin into homogentisinic acid, a fact which turns the clinician's mind at once toward a possible explanation of the pathogenesis of alkaptonuria in human beings, especially as tyrosinase has already been demonstrated in the tissues of certain animals by Biedermann and by v. Fürth and Schneider. It appears probable that the melanin of the cuttlefish is formed through the oxidizing influence of a tyrosinase.

A fifth oxidizing ferment present in the pancreas, salivary glands, spleen, bone marrow and thymus, but not in the lymph glands, breasts, muscles, lungs, brain, adrenals, testicles or kidneys, is that shown by Rochman and Spitzer[4] to influence the synthetic origin of indophenol in the body. They call it indophenol-oxydase.

Perhaps the most important, at any rate the best studied, of the oxydases thus far discovered in living tissues is the aldehydase of Jaquet,[5] isolated first in Schmiedeberg's laboratory. It is very widely distributed in the animal body, occurring in the liver, spleen, salivary glands and thyroid, though it has not yet been demonstrated in the pancreas, muscles, breast or bone marrow, from which organs it appears to be absent. An interesting fact brought out by Jacoby is that, while abundant in the cortex of the suprarenal body, it is absent from the medulla of that organ, just the opposite of adrenalin, which occurs in the medulla but not in the cortex. This aldehydase has the power of oxidizing aldehydes of both the aromatic and fatty series to their corresponding acids. Thus salicylic aldehyd is oxidized by it to salicylic acid and formaldehyd to formic acid. It has been found possible to isolate this ferment comparatively easily, the method of precipitation by uranyl acetate worked out by Jacoby[6] being especially successful for the purpose. It is a true "contact substance" in the chemical sense, as the ferment is not used up during the single reactions, but only very gradually becomes inactive. The laws to which its activities are subordinate have been carefully studied by Medwedew.[7] In certain pathologic conditions the relations of aldehydase have been examined; thus it is not absent from the liver in phosphorus poisoning nor in diabetes mellitus (Jacoby), though it appears to be lessened in amount in the livers of children dead of gastroenteritis (Pfaundler[8]).

The multiplicity of oxydases is an interesting feature. There is no general oxydase, but specific oxydases are active for the individual oxidizing reactions. On the one hand, a given organ may contain one oxydase and not another, and on the other different oxydases may be isolated from one and the same organ. The comparative table of Rosell,[9] showing the distribution of various oxidizing ferments, is of interest in this connection.

As we pointed out in a previous article, the exact chemical nature of the ferments is as yet unknown. The chemistry of the constitution of oxydases is almost as obscure as is that of other enzymes. It seems clear, however, that they are not albumin bodies or nucleoproteids, and there is a good deal of evidence that they represent organically bound metals, most probably iron and manganese.

THE YELLOW FEVER.

The situation has not changed materially during the week. In New Orleans the improvement has been so well maintained that there is a menacing relaxation of public efforts at mosquito destruction. At two points in Louisiana—Tallulah and Patterson—the conditions are grave, a large proportion of the population ill, no funds to work with, and the populace hostile to the mosquito doctrine. The state has offered a small sum if the citizens do their part, and Dr. Charles L. Chassaignac, New Orleans, has left his practice and volunteered to take charge at Tallulah in the hope of arousing the community to help itself, and with a view to proper care of the sick. Reference to our news columns will show that the conversion of Governor Vardaman of Mississippi to rational methods is complete, thorough and creditable. No doubt this excellent result is due to the personality and enlightened persistence of Dr. John F. Hunter, Jackson, secretary of the State Board of Health, and of the officers of the U. S. P. H. and M.-H. Service, with whom Mr. Vardaman has been recently thrown in contact. Mississippi has a number of infected points, the governor and communities admit the failure of shotgun quarantine, and scientific methods under the supervision of the U. S. P. H. and M.-H Service are being vigorously applied. The muddle in Arkansas is astonishing, but it is too early to arrive at final conclusions as to the merits of the controversy. Members of the old State Board of Health appear to have resigned as a matter of principle and as a protest against irrational and overriding methods of Governor Jefferson Davis, and if this prove to be the case, physicians will regret that the governor was able to find other medical men to take the places vacated under such circumstances. Judgment must, however, be suspended until further facts come to light. It looks as if Florida might have a considerable epidemic from the Pensacola focus. Everywhere in the infected area the facts are fully confirming the mosquito conveyance. For instance, Tallulah, La., early in the epidemic had a few cases which ran their course without others appearing and for two weeks or more no further cases occurred, so that it was hoped the infection had run out. However, from lack of funds and from popular disbelief in the part played by the stegomyia, no serious effort was made to destroy the mosquitoes and now the community is more generally infected and is in more grave condition than any other yet involved, the infection not coming from outside but from the infected mosquitoes allowed to thrive after the first cases occurred.

"PICTURES THAT TELL THEIR OWN STORIES."

Under the above caption, the *Ladies' Home Journal* for September devotes a page to pictures that tell their own stories most effectively. One of the pictures is a reproduction of a testimonial from a congressman, in which he tells how satisfactory he found peruna for grippe and catarrh; parallel with this picture is a reproduction of a letter from the same congressman, in which he states that the letter referred to is a forgery and that neither he nor his family ever used the nostrum. Another is a photograph of an advertisement showing how the names obtained by patent medicine concerns—often under the promise to keep them confidential—are sold or rented. A photograph of a label taken from a bottle of Mrs. Winslow's soothing syrup, bought in England, shows that there they have to acknowledge that it contains morphin; for on the label is the legend: "This preparation, containing, among other valuable ingredients, a small amount of morphin, is in accordance with the pharmacy act hereby labeled POISON." The most "telling" picture in the group is one that contains a reproduction of an advertisement which tells us about Mrs. Pinkham: "Having had considerable experience in treating female ills . . . it was easy for her ailing sisters to pour into her ears every detail of their suffering. . . . Any woman, therefore, is responsible for her own suffering who will not take the trouble to write to Mrs. Pinkham for advice." Parallel with this is a photograph of the tombstone in Pine Grove Cemetery, Lynn, Mass., which bears this inscription: "Lydia E. Pinkham, born Feb. 9, 1819, died May 17, 1883."

THE CHOLERA.

From the press dispatches we learn that Asiatic cholera has again invaded Western Europe from Russia, where it has probably been more or less epidemic for some time, notwithstanding the alleged statement of an official commission that no case has occurred in the Russian empire since April 21. The cases thus far reported are confined to certain districts of Prussia, one or two exceptional cases occurring in Hamburg. While it is not anticipated that there will be any repetition of the epidemic of thirteen years ago, the sanitary authorities are wide awake to a certain degree of peril in the situation, and even in this country steps have been taken by the Public Health and Marine-Hospital Service to prevent any possible importations of the disease. The sanitary conditions in Russia are never entirely satisfactory, and it was pointed out some time since that, owing to the internal disturbances and to the fact that the war is draining the country of physicians, the dangers of a cholera epidemic are imminent. With an ignorant populace, a certain degree of weakening of authority and a general lack of intelligent medical supervision in many extensive districts, the fact of cholera leaking over the borders is not at all an encouraging one. It will be very surprising indeed if Russia does not suffer severely from this cause, and it will require active measures on the part of her neighbors to prevent an extension of her misfortunes beyond her boundaries. The extensive immigration of Russians into this country, which does not seem likely to be soon checked, will call for vigilance on the part of health officers at seaports where the immigrants land, and it is reported that several Russian immigrants have been rejected because they came from cholera-infested districts. It is fortunate, however, that, with our better knowledge, cholera is not likely to become the formidable scourge of previous years, but it would not require a very extensive neglect of necessary precautions to make it even now a serious matter.

FEE BILLS LEGAL.

Down in Texas, not long since, some trustophobiac thought he saw in a fee bill of a local medical society a violation of the antitrust laws of the state, and promptly submitted the matter to the attorney general. That official took the matter seriously enough to give a written opinion, which probably settled the matter, in the mind of his inquirer, as far as Texas is concerned. According to the opinion of the attorney general, it is not a restriction of the free pursuit of business for any person or set of persons to refuse to sell their professional services for less than the value they themselves place on them. This would seem to be sufficiently self-evident, but perhaps it is just as well to have a legal opinion on the matter. Since we hear so much of "medical trusts" whenever physicians unite for scientific purposes to protect themselves from imposition or to secure their rights, a little surplusage of legal utterance of common sense will do no harm.

THE PROGRESS OF PURE FOOD LAWS.

The pure food issue stirs both commerce and politics. The developments of the next six months promise extreme interest. There has recently been organized the "National Fruit Manufacturers' Association," with from 50 to 75 members. Its announced object is to protect the public from adulterated foods and drugs. Among other remarks, the secretary of the new association said: "There will be a pure food law enacted at the next congress; of that there is no doubt. What we must decide is, shall it be a pure food law of the manufacturers or of the food commissioners?" At Portland, the National Association of State Food and Dairy Departments decided that the United States Department of Agriculture has set up impracticable standards and that each state should have its own standards and methods, just what the adulterators hope for. It is a question in the minds of many as to whether around state insurance commissionerships or food commissionerships center the most scandals and greatest graft. Of course honest men do get into these positions, but not always. Only two years ago, one food commissioner withdrew from the association on the ground that it was being used for the personal profit —graft—of its members. Reverting now to the remark of the secretary of the Food Manufacturers' Association, it is clear that the medical profession and the public want neither "a pure food law of the manufacturers" nor "of the food commissioners." Congress is going to pass a pure food law, and we shall be compelled to put in sleepless nights to be sure that the measure is not passed in emasculated and deformed shape.

Medical News

ARKANSAS.

Physician's Name Dropped.—The name of Dr. Oscar S. Burrow, Hot Springs, has been dropped from the registered list by order of the Secretary of the Interior.

Appeal to Annul Rule.—The attorney for the unregistered physicians of Hot Springs has made a direct appeal to the President asking him to direct Secretary Hitchcock to recall all rules relating to the creation of a Federal Medical Board, and to prescribe the qualifications a physician must pass to be at liberty to use hot baths in the care of his patients. The petition was referred by the President to the attorney general.

State Board of Health Changes.—Drs. George M. D. Cantrell, president of the State Board of Health, Robert H. Christian, secretary, William H. Miller and William B. Hughes, all of Little Rock, have resigned from the State Board of Health on account of friction between the board and the governor of the state regarding the quarantine situation. Dr. Joseph P. Runyan has been appointed president, Dr. Joseph P. Shephard, secretary, both of Little Rock, and Drs. Robert A. Hilton, Eldorado, and Eugene H. Abington, Beebe, have been appointed to succeed the retiring members.

Personal.—Dr. Thomas B. Bobbitt has been made chairman of the Beebe Board of Health.——Dr. Henry Owen, Newport. has been elected president of the Jackson County Board of Health.——Dr. James M. Gist, Beebe, has been seriously ill with heart disease.——Dr. William H. Barry, president of the Federal Medical Board, Hot Springs, is critically ill with intermittent fever at his home.——The Ashley County Board of Health has been organized with Dr. William E. Easter. president, and Dr. William S. Norman, secretary, both of Hamburg.——Drs. J. Pell Baker, Morrell, Henry E. Cockerham, Portland, and J. L. Parker, Snyder, were appointed vice-presidents for their respective districts.——Crawford County Board of Health has been organized with Dr. William L. Parchman, Van Buren. president, and Dr. Sharp, Alma. secretary.——Drs. S. G. Robertson, Monticello, John T. Blanks, Baxter. and Sidney Harris, Wilmar, have been appointed members of Drew County Board of Health.

CALIFORNIA.

Memorial to Dr. Brown.—As a fitting testimonial of her worth, the friends of the late Dr. Charlotte Blake Brown have raised a fund of $3,000 to endow a bed in the Children's Hospital of San Francisco.

Loses License.—On the allegation of unprofessional conduct, the license of Dr. Jessie Aldrich, Los Angeles, was revoked, August 22, by the State Board of Medical Examiners. The specific charge against Dr. Aldrich was that she had advertised a "sure cure" for cancer.

Chiropractic Found Guilty.—Thomas H. Story, a chiropractic of Los Angeles, was fined $500, August 27, with the alternative of 180 days' imprisonment in the city jail, for practicing medicine without a license from the State Board of Medical Examiners. He threatens to appeal, and says that the physicians of a dozen schools of drugless remedies will aid him in his fight.

Personal.—Dr. Frederick J. Crease, Bakersfield, has resigned as president of the Kern County Medical Association, and Dr. Henry W. Owen, Bakersfield has been elected in his stead.——Dr. John W. Trueworthy, Los Angeles. is reported to be in a critical condition from concussion of the brain as a result of the wreck of a Pasadena electric car, August 16. ——Dr. Albert W. Kirk has been appointed volunteer oculist; and Drs. Emma C. La Fontaine and L. H. Young. all of San Francisco, have been appointed volunteer school inspecting physicians.——Dr. Raymond Russ, San Francisco, has been appointed instructor in surgery in the medical department in the University of California.——Dr. Dumont Dwire, Oxnard. health officer of Ventura County. left for Europe August 23. ——Dr. Caroline S. Merwin, Oakland, has gone to China to take charge of a Presbyterian Missionary Hospital at Chinaufu.

COLORADO.

Appeals from Decision.—Dr. William M. Bonnet. Denver. has asked for a new trial in the damage suit decided against him in favor of Mrs. Emma C. Foote, for malpractice in May last.

Hospital Reopened.—The Miners' Union Hospital at Telluride, which has been closed since the miners' strike in September, 1903, was reopened September 1, and will be in charge of Dr. John G. Sheldon.

Personal.—Dr. Lewis E. Lemen, Denver, has been appointed chief surgeon of the Moffat Railroad, and Dr. Hugh L. Taylor assistant chief surgeon.——Dr. Maurice Kahn, Leadville, has been appointed captain and assistant surgeon in the National Guard of Colorado.—Police Surgeon Dr. Francis E. Prewitt, Denver, has resigned.

DISTRICT OF COLUMBIA.

Personal.—On the recommendation of the superintendent of the Washington Asylum, Dr. J. H. Constas was appointed resident physician at the Asylum Hospital, vice Dr. T. J. Sullivan, removed.——Dr. Henry C. Macatee has been appointed medical instructor of public schools, and Dr. Edmund Barry a member of the board of police and fire surgeons.

Typhoid Fever.—On August 26, 16 new cases of typhoid fever were reported at the Washington health office; the number reported since July 1 is now 408. and 286 patients were under treatment on August 25. The district officers do not look for a change in conditions until the middle of September, when the filtration plant is expected to be in full operation.

FLORIDA.

Personal.—Dr. Thomas A. Williams, Jacksonville, is spending the summer abroad.——Dr. John W. Clerke, Green Cove Springs, who has been seriously ill, has returned from Jacksonville and is now convalescent.

Health Board Official Dies.—Mr. R. L. Durrance, executive clerk for the State Board of Health for a number of years, died at his home in Jacksonville August 7 from appendicitis, aged 28. He was an efficient and faithful official and his death will prove a serious loss to the board.

Medical Examiners Approved.—Drs. J. D. Fernandez, Jacksonville; J. Harris Pierpont, Pensacola; Henry E. Palmer, Tallahasse; J. Harrison Hodges, Gainesville; John B. Maloney, Key West; Alonzo L. Blalock, Madison, and R. L. Harris, Orlando, have been appointed members of the State Board of Medical Examiners.

State Health Board Formed.—Captain Harry Fozzard, Jacksonville, has been appointed, and Dr. Horace L. Simpson, Pensacola, and Hon. E. M. Hendry, Tampa, have been reappointed members of the State Board of Health. Dr. Joseph Y. Porter, Key West, holds over as state health officer, as he was elected for that office for four years in February last.

GEORGIA.

Will Probated.—The will of the late Dr. Robert H. Hightower, Dublin, was probated August 10. The estate is appraised at about $60,000.

[illegible] itarium.—The trustees of the State [illegible] ask for an appropriation for 1906 [illegible] of $407,000.

Sanatorium Opens.—The Piedmont Sanatorium opened at Atlanta under the charge of Dr. Ludwig Amster, with Dr. Maloney, formerly of the Grady Hospital, as assistant. Dr. Floyd W. McRae will have charge of the surgical department.

Personal.—A fire in the office of Dr. J. Clarence Johnson destroyed his books, papers and instruments July 28.——Dr. Charles F. Benson, president of the Atlanta Board of Health, is seriously ill with typhoid fever.

Hospital Notes.—The Wesleyan Memorial Hospital, Atlanta, was formally dedicated with appropriate services August 19. Bishop Warren Candler delivered a dedicatory address, and Dr. J. Scott Todd spoke on behalf of the medical board of the [illegible] has just built a new city hospi[illegible]ment of about $12,000.——The Macon city hospital will receive from this time on $5,000 annually from Bibb County and a like amount from the city.

Beneficiary Scholarships.—The following appointments to the beneficiary scholarships at the Medical College of the University of Georgia have been made by the governor: C. M. White, Columbus; J. D. Delmar, Whitesville; G. T. Bernard, Athens; Frank C. Harpe, Buena Vista; W. H. Sutton, Swainsboro; L. L. Lanier, Stillmore; S. T. Register, Lennox; G. T. Crozier, Cedar Springs; Edmund W. Carter, Carsonville; Guy G. Lunsford, Americus; P. J. Brown, Newman; W. B. Spain, Talbotton; E. S. Harris, Bethlehem; M. F. Hurst, Monroe; W. B. Goddard, Milner; George L. Johnson, Yatesville; W. A. Arnhold, Carrollton; Sam C. Cheney, Silver

Creek; O. S. Wood, Madison; Charles T. Ridley, Hillsboro; T. L. McCurry, Centerville; J. S. Burrell, Clayton; Fred A. Lowe, Augusta; C. E. Stapleton, Gibson; J. D. Peacock, Quitman, and Henry Smith, Sirmans.

ILLINOIS.

Physicians Injured.—Dr. Ralph E. Niederinghaus, Granite City, was painfully, though not seriously, injured in a runaway accident August 31.——Dr. Henry C. Fairbrother, one of the oldest practitioners of East St. Louis, was injured internally by falling into an excavation August 31.——Dr. George M. Straight, Winchester, was painfully bruised in a runaway accident August 31.

Chicago.

Personal.—Dr. N. Senn returned from Greenland September 11.——Dr. Truman W. Brophy has returned after a summer abroad.

Fined for Illegal Practice.—H. Wolff, prosecuted by the State Board of Health on a charge of practicing medicine at 503 Sangamon street without a license, was fined $200 and costs September 5.

Smallpox Checked.—There are at present only eight smallpox patients in the Isolation Hospital, and all of these are convalescent. There have been no new cases for two weeks, and it is hoped that the disease is effectually checked.

Decrease in Typhoid Fever Death Rate.—Fourteen years ago Chicago had the highest typhoid fever death rate of any large city in the world, amounting to 17.22 per 10,000 population. For 1904 the rate was only 1.92 per 10,000, which places Chicago among the lowest, in this regard, of all large cities.

The Unstable Laboratory.—It is now currently reported that the laboratory of the Health Department, which was reported, first, to have been moved to the city building at Michigan avenue and Fourteenth street and, then, to the Galbraith building at Franklin and Madison streets, will remain in its old quarters in the City Hall.

Acquire Property.—The Illinois Charitable Eye and Ear Infirmary has acquired one hundred feet additional frontage on Peoria street for $20,000, on which will be erected a fireproof addition to the present structure. The legislature recently appropriated $75,000 for this purpose.——The Washington Park Hospital has acquired a lot on Sixtieth street, 50 by 150 feet, on which an addition will be built.

The Week's Deaths.—During the week ended September 9, 500 deaths were reported, 10 less than for the previous week and 57 more than for the corresponding week of 1904. The respective annual death rates per thousand are 13.09, 13.35 and 11.98. Of the deaths, 147 were of infants under 1 year. Acute intestinal diseases caused 124 deaths; violence, including suicide, 55; consumption, 44; nephritis, 38; nervous diseases, 29; pneumonia, 28, and heart disease, 27.

IOWA.

Hospital Burns.—The Somers Hospital, Grinnell, was burned to the ground early on the morning of August 30. No casualties occurred, but the loss is about $3,000.

Carbolic Acid Sale Regulated.—The physicians of Des Moines are heading a movement to have a law passed by the legislature which will place carbolic acid on the same basis as morphin and other drugs as regards its sale. The necessity for this law is evident from the increasing number of cases of suicide from carbolic acid, which can be obtained at present without the restrictions under which cocain, morphin and other poisons are sold.

Medical Colleges Open.—The Sioux City College of Medicine opens for its fall term September 19. The new members of the faculty are: Dr. E. A. Jenkinson, professor of embryology; Dr. W. R. Mahood, professor of physiology; Dr. Isaac E. Nervig, assistant professor of anatomy; Dr. E. Ruel Wheeler, assistant professor of physiology, and Dr. Alexis M. Warren, professor of surgery.——Keokuk Medical College has added to its faculty Drs. Frank B. Hiller, Kahoka, Mo.; Frank P. Norbury, Jacksonville, and C. R. Armentrout, Keokuk.

Personal.—Dr. William G. Morton, Iowa Falls, has been appointed assistant surgeon at the Soldiers' Home, Marshalltown.——Dr. Channing E. Dakin has been appointed school physician of Mason City.——Dr. Lucius French, Davenport, who was recently operated on for gallstone disease, is making satisfactory progress.——Dr. William B. La Force and wife, Ottumwa, arrived from Europe August 30.——Dr. E. R. Walizer, Des Moines, was committed to the State Insane Hospital at Clarinda August 21.——Dr. Timothy J. Caldwell, ex-senator, Adell, is critically ill with rheumatic endocarditis.——Dr. A. A. Noyes, Mason City, has been made a life member of the Cerro Gordo County Medical Society.——Dr. Kirk Jaenecke, Clinton, sails for Europe from Montreal this month.

MARYLAND.

Personal.—Dr. Herbert E. Zepp has formed a partnership in practice with Dr. A. B. Glascock of St. Michaels, Talbot County.

Good Roads Physician.—Dr. V. M. Reichard of Fair Play is displaying talent and public spirit in building good and cheap roads in his section. In addition to a large practice he holds the office of road supervisor of his district. He finds it possible to construct macadamized roads, if there be no grading, for about $550 per mile. His crushed stone costs him about 45 cents a perch.

Baltimore.

Injured.—Dr. Edwin Geer, commander of the Maryland Naval Reserves and surgeon of the city fire department, was painfully injured September 6 by falling from a street car.——Dr. Joseph C. Wunder, in an effort to save a pigeon from a cat September 1, fell from a porch and broke his jawbone.

Personal.—Drs. William Green and Thomas H. Buckler are in Paris.——Dr. John McF. Bergland has gone to North Hatley, Canada, to hunt deer.——Dr. Ira Remsen has returned from his summer vacation at Northeast Maine in order to attend a meeting of the sewerage commission, of which he is a member.

Sewerage System.—The first practical step was taken September 7 by the commission engaging a board of three advisory engineers, to study the situation, to recommend the best method for disposal of sewage and to give an estimate of its cost. It was decided that the sewage before emptying into the bay or river shall be as pure as possible, to avoid possible injury to the oyster and fish industry of the state. The advisory engineers selected are Messrs. Rudolph Hering of New York, Frederick P. Stearns of Boston, and Samuel M. Gray of Providence, and they were requested to recommend a chief engineer to the commission, and to present their report not later than April 1, 1906, and earlier, if possible. Each of the three advisory engineers receives $5,000 as a fee, and additional $5,000 for outside work to be done and traveling expenses.

NEW JERSEY.

Camden's Health Report.—During August only 16 cases of contagious disease were reported to the Board of Health as follows: Scarlet fever, 5; typhoid fever, 2; diphtheria, 1, and tuberculosis, 8.

Diphtheria Epidemic.—An epidemic of diphtheria is reported at Port Republic, near Egg Harbor City. A number of deaths are said to have occurred, and public meetings are prohibited for the time being.

Hospital Report.—The report of Cooper Hospital, Camden, for August shows that 84 patients were admitted to the hospital during the month, and that there were 50 remaining September 1. In the dispensary 412 new cases were treated, and 1,352 visits were made.

Lower Death Rate.—The annual report of the New Jersey State Board of Health, just issued, shows that the death rate in the state per 1,000 of population, for 1903, was 15.87, or .04 less than for the previous year. There has been, generally speaking, a decrease since 1892, when the rate was 21.62 per 1,000. The births for the year were 37,242, or 18.47 per 1,000 of population, and the deaths 31,820.

NEW YORK.

Property Given Hospital.—At the gift fair for the German Hospital, Buffalo, a two-story brick house and lot at 934 Fillmore Avenue, valued at $5,000, was presented to the hospital.

More Insane Patients Transferred.—The transfer of 500 patients from King's County State Hospital to the Rochester State Hospital and Willard State Hospital was completed September 7. There were 290 patients transferred to the Rochester State Hospital and 210 to the Willard.

Buffalo Wants Better Water.—An advisory commission composed of expert engineers has been appointed to pass on plans for the improvement of the city water system. The board consists of Col. Thomas W. Symons, U. S. A., Rudolph Hering of New York, and Gen. George S. Field of Buffalo.

Buffalo Personals.—Drs. Roswell Park and Edgar McGuire, who sailed from Montreal on the *Victorian*, were obliged to transship when their steamer grounded in the St. Lawrence above Quebec, took train to New York and sailed on the *Caronia* next day.——Dr. Floyd S. Crego returned home from a nine months' visit to Europe.——Dr. Charles G. Stockton has returned from the Pacific coast.

New York City.

Seven More Suspects.—Seven voyagers on the steamer *Advance*, from Colon, were detained at quarantine and taken to Hoffman's Island for observation on account of high temperatures.

Fire at Child's Hospital.—On September 8 fire broke out in the wing of the Child's Nursery and Hospital, which has been leased by the Rockefeller Institute for Medical Research. Very little damage resulted.

Personal.—Dr. and Mrs. Charles Phelps arrived on the *Koenigin Luise* September 8.——Dr. James E. Newcomb's house was broken into by thieves, who carried away about $300 worth of jewelry.——Dr. M. C. O'Brien has returned after two months' vacation at Old Orchard, Maine.

Ambulance Accident.—The Kings County Hospital ambulance, while going at full speed, collided with a large touring car. Two of those in the touring car are expected to die. The ambulance surgeon escaped with slight injuries and explained that the high speed of the ambulance was deemed necessary on account of the condition of the patient he was taking to the hospital.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended August 26, 429 cases of tuberculosis, with 175 deaths; 329 cases of typhoid fever, with 20 deaths; 132 cases of diphtheria, with 15 deaths; 115 cases of measles, with 6 deaths; 54 cases of scarlet fever, with 2 deaths; 14 cases of cerebrospinal meningitis, with 15 deaths, and 3 cases of varicella.

Still Refuse Use of Mails.—The District Court of Washington, D. C., denied the application of the New York Institute of Physicians and Surgeons for a mandamus compelling the postmaster general to restore to the institute the use of the mails which he had previously denied by an official order. The court held that there was reasonable ground for the conclusions reached by the department.

New Graft Game.—There has been a man at work in the Bronx and elsewhere who calls on physicians, telling them of an imaginary ill. The doctor makes an examination and finds the man's heart on his right side. The patient seems alarmed and the physician becomes interested. Then the patient makes a strike for $2 or $5, promising to call again. This new game has been worked successfully.

Personal.—Dr. George W. Kunz has been appointed by the state department a delegate to the International Congress for the Study of Radiology and Ionization, to be held in Leige, Belgium, this month.——Dr. and Mrs. Charles E. Nammack arrived on the *Oceanic*, August 31.——Drs. W. B. Anderton and George W. Jacoby arrived on the *Kaiser Wilhelm der Grosse*, August 29.——Dr. and Mrs. Edwin Atwood sailed for Europe on the *Finland*, September 2.

To Kill Staten Island Mosquitoes.—The contract for draining the south marshes of Staten Island has been awarded and work will be begun at once. Petroleum-spraying machines were sent to infected spots, and the people were asked to cooperate with the authorities in combating these pests, and as a result there has been a marked decrease in the annoyance from mosquitoes. Dr. Doty expresses himself as confident that in due time the mosquito will be extirminated from this locality.

Keepers Locked Up with the Insane.—Two attendants of the Manhattan State Hospital for the Insane, on Ward's Island, who had four demented patients in charge, were locked up on September 1 by the Chicago police on the suspicion that they were trying to foist their patients as public charges on the state of Illinois. This has caused indignation at the hospital and at the office of the State Board of Alienists, as the men were provided with all credentials necessary to show that the patients were residents of the state of Illinois.

Record Month for Typhoid.—Between July 29 and August 30 the typhoid fever cases reported to the *Board of Health* numbered 1,128. This is the highest number of cases in one month for years. The cases in August of last year numbered 413. From Saturday, August 26, to Wednesday, August 30, 157 cases were reported, 98 of which appeared in Brooklyn, and during the month there have been 579 cases in that borough. Few are now appearing in the Bath Beach section, where they were especially numerous a few weeks ago.

Sue City for Poisoning.—As the result of the death of two men in the Cumberland Street Hospital, Brooklyn, after carbolic acid had been administered instead of whisky, by mistake, claims for damages amounting to $50,000 have been filed against the city. Both men were in a serious condition on the night of Dec. 27, 1904, when whisky was ordered and the nurse administered carbolic acid by mistake, but Superintendent Bacon claimed that the men would have died in any case and the carbolic acid only hastened the end.

Activity at Quarantine.—As the result of the discovery of cholera at Hamburg a conference was held at Quarantine, September 1, between Dr. Alvah H. Doty, health officer of the port, and representatives of the transatlantic steamship lines, at which it was agreed that extra precautions should be observed in receiving immigrants from German ports. All passengers from infected localities will be kept at the ports of embarkation under medical inspection for six days previous to departure. During the voyage to this port all steerage passengers will be subjected to medical examination and inspection twice a day, and everyone found ill will be isolated.——The Panama Railroad steamer *Havana* arrived at Quarantine August 31 with one case of yellow fever aboard. Five passengers with suspiciously high temperatures have been held and are being closely watched.——The Portuguese steamer *Peninsular*, which arrived in port September 1, had on board one case of smallpox. The passengers who were exposed to contagion were sent to Hoffman Island for observation.

Prospect of Filtered Water Supply.—A pamphlet entitled "Report on Filtration of the Water Supply of New York City," by Dr. Thomas Darlington, commissioner of health, has been published, which sets forth the reasons why a filtration plant should be installed for this city. Dr. Darlington presents a number of carefully prepared charts showing the reduction of typhoid mortality by the filtration of water. During the past five years the number of cases of typhoid fever in New York City are as follows: For 1900, 2,658 cases, with 718 deaths; for 1901, 2,748 cases, with 721 deaths; for 1902, 3,871 cases, with 765 deaths; for 1903, 3,671 cases, with 653 deaths; for 1904, 3,412 cases, with 661 deaths. During the same period the deaths from diarrheal diseases were: For 1900, 6,695; for 1901, 6,773; for 1902, 5,767; for 1903, 5,120, and for 1904, 6,527. It is probable that many of these deaths were due to contaminated water. Dr. Darlington estimates that the cost of filtering the water supply of 500,000,000 gallons daily would be $17,000,000, and the annual cost of operation $900,000.

Report of the Pneumonia Commission.—This commission, which was appointed in August, 1904, by the Board of Health, and began its work in October, has made public its first report. The commission consisted of Drs. Edward G. Janeway, William Osler, William H. Welch, T. Mitchell Pruden, Theobald Smith, Frank Billings, John H. Musser, L. Emmett Holt, Francis P. Kinnicutt, Thomas Darlington and Hermann M. Biggs. This report showed that the pneumonia germs were found in 95 per cent. of those examined. In discussing this question, it says that there is a possibility that pneumococci of greater virulence than those found in the mouth are inhaled with the air current, determining the onset of the disease. There would seem to be evidence that the pneumococcus may suddenly appear in the so-called normal mouth, that certain individuals carry the organism in their mouths for considerable periods of time, and that even those persons in whom the organism can not be demonstrated at every examination may harbor the pneumococcus in the less accessible portions of the respiratory tract. The study of the communicability of pneumonia led the commission to the conclusions that (1) "normal" individuals in whose mouths the pneumococcus is repeatedly found to be absent may acquire the organism by association with cases of pneumonia or with "positive normal" persons; (2) the handkerchiefs of pneumonia and "positive normal" cases may be regarded as means of transportation of the pneumococcus from person to person. A vigorous attempt was made to develop a serum which might be used either to ward off the pneumonia or to assist in ridding the blood of the germs after the disease had been contracted. They found that all pneumococci were agglutinated by means of pneumococcus immune serum; an immune pneumococcus serum was found capable of agglutinating various pyogenic streptococci, certain atypical organisms and several strains of the *Streptococcus mucosus capsulatus*; the serum of pneumonia patients varied in its power to agglutinate different pneumococci. Some strains were agglutinated, others not.

PENNSYLVANIA.

Personal.—Dr. Philip Y. Eisenberg, Norristown, was thrown from his carriage, September 5, and sustained painful but not serious injuries.

Bequest to Hospital.—The late Bethuel T. Hall has bequeathed to the Chester Hospital $3,000 as an endowment fund, the income of which is to be used in the general conduct of the hospital. The endowment is made in memory of his mother, Sarah Hall, and his aunt, Charlotte Cloud.

Oil City Working Against Tuberculosis.—The Grand View Institution, Oil City, which is devoted to the care and treatment of consumptives, has raised $6,500 and expects to erect an additional building to accommodate twenty-four patients. At present the institution accommodates fifteen patients, some of whom are living in tents.

Typhoid at Nanticoke.—An epidemic of typhoid fever has broken out in Nanticoke, near Wilkesbarre. Up until September 7, 224 cases had been reported. A committee appointed by the Board of Health to investigate the water supply found one house in which typhoid fever existed and from which drainage contaminated the streams leading to the reservoir. The official report of the investigation has not yet been made public.

Medical Society Pays Costs.—In the case of "Dr." A. Witman, charged by the Monessen Medical Society with practicing medicine without a license, the defendant was acquitted and the costs charged against the medical society. This peculiar result was attained because when the case was called the defendant did not appear. The prosecuting attorney insisted that his cash bail bond of $400 be forfeited, but the defendant's attorney, declaring that he would try the case without the defendant, obtained a favorable decision for his client.

Doctored Milk on the Decrease.—Reports of the Dairy and Food Commission during the past month show a decrease in the amount of doctored milk dispensed. Of a total of 460 samples of milk and cream taken by the Dairy and Food Commission agents for analysis, only 5 were such as to justify prosecution. Two years ago examination revealed that more than 33 per cent. of the samples taken were preserved with formaldehyd, boric acid, or were watered, skimmed or colored in violation of law. The total receipts of the Dairy and Food Commission during June, July and August were $13,527.14, nearly all of which was fines. The receipts since January only for oleomargarine and renovated butter licenses were $31,000.

Personal.—Dr. J. Edward Dickinson, Harrisburg, has been elected anesthetist on the staff of the Harrisburg Hospital. ——Dr. M. C. Womack has gone on duty as resident physician at the Reading Hospital.——Dr. Harry J. Bell, Dawson, is taking a trip to the Pacific coast.——Drs. A. E. Mahood and G. R. Reid have taken up their duties as internes at Hamot Hospital, Erie.——Dr. Jacob O. Knipe, Norristown, fell while alighting from a trolley car, dislocating his shoulder and injuring his right knee.——Dr. William H. Lauman, Mount Holly Springs, has had a cerebral hemorrhage.——Dr. Arthur S. Brumbaugh, Altoona, reached New York from Italy September 7.——Dr. Charles B. Hough, Ambler, sustained a contusion of the leg in a train collision, September 4, at Brush, Colo.——Dr. A. F. Brundage, Hazleton, who recently resigned as United States consul at Aix-la-Chapelle, has returned to his farm at Conyngham.

Philadelphia.

Love Powders Dispensed.—John Brady, a self-styled doctor, with offices at 1208 Pine street, was arrested, charged with selling powders that were warranted to restore connubial happiness. The doctor's patrons asserted that the powders did not possess the necessary charms. He was held in $500 bail for trial.

Hospital Reports.—During August, Mount Sinai Hospital treated 3,825 cases, of which 423 were accidents, and 71 patients were admitted to the wards.——Samaritan Hospital treated 1,678 patients in the dispensaries; 257 of these were due to accidents, and 72 were admitted to the wards.——The Germantown Hospital treated 1,755 cases in the dispensary, and 283 patients were treated in the wards.

Mutual Aid Society of County Medical Society.—The Philadelphia County Medical Society gives financial aid to the widows and orphans of its members and to members in distress. The society also has a private room in the Polyclinic Hospital devoted to the care of sick members. Any information concerning the aid association can be obtained from Dr. Joseph S. Neff, treasurer, 2300 Locust street.

Health Report.—The deaths from all causes for the week numbered 374. This is below the normal, as there were 434 deaths in the previous week and 400 in the corresponding week of last year. The principal causes of death were: Typhoid fever, 12; whooping cough, 5; tuberculosis, 55; cancer, 20; apoplexy, 15; tetanus, 1; heart disease, 23; acute respiratory diseases, 16; gastritis, 5; enteritis (under 2 years), 37; enteritis (over 2 years), 8; Bright's disease, 29; accidents, 22, and marasmus, 13.

Personal.—Dr. Harry L. Randal escaped serious injury in a train wreck in Denver, Colo., September 5.——Dr. Thomas C. Potter, Germantown, has sailed for Europe.——Dr. J. Frank Meade, while returning from Atlantic City in his automobile September 5, was struck in the face by a stone thrown by some miscreant and painfully injured.——Dr. Fairfax Irwin, who was detailed to study the cholera situation in Germany, has, by order of the United States Public Health and Marine-Hospital Service, postponed his departure.——Dr. Richard Flavel Woods narrowly escaped a serious accident, August 13, when his automobile ran into a ditch and turned completely over, burying Dr. Woods beneath it. Before he was rescued the flames of the exploding gasoline had caused serious burns.——Drs. Lawrence F. Flick, Joseph Walsh, Mazyck P. Ravenel and Daniel J. McCarthy sailed, September 16, to attend the International Congress on Tuberculosis in Paris.

Organizing the Profession.—The weekly roster of the medical organizations of Philadelphia has the following to say concerning the organization of the profession: "Consolidation of common interest has in recent years marked all of the activity, and the medical profession forms no exception to this world-wide movement. Its newest development tends to confirm the dictum that in union is strength. In the American profession, with the county society as the unit, membership therein leading through the state society to the national association, we find physicians organizing with an eagerness never before shown in any section of the land. Stimulated by this crusade, its latest phase is presented in a systematized enrollment of the practitioners of the great cities. The Philadelphia County Medical Society is a noteworthy example in that, through originating the "branch" feature, the membership is now at the 1,200 mark, with 1,800 in view. Branch societies will hold monthly meetings in, ultimately, every section of the city, and the scientific value of the meeting programs has risen just as steadily, so that systematized postgraduate courses of instruction for members may be the final object."

TENNESSEE.

New Infirmary in Memphis.—Drs. Frank D. Smythe and Bennett G. Henning, Memphis, are about to erect a sanitarium in Memphis, to cost $30,000.

College Merger.—The Tennessee Medical College, Knoxville, has decided to become the medical department of Lincoln Memorial University, Cumberland Gap, and the new hospital which is being erected by the college will be known as the Lincoln Memorial Hospital.

Personal.—Dr. Archibald L. Elcan, Memphis, was tendered a farewell dinner, September 2, by seven of his professional associates. He leaves for Los Angeles, Cal., in a few days. ——Dr. Raymond Wallace, Chattanooga, returned from Europe on the *Baltic* August 17.——Dr. Newman Taylor, Brunswick, has been appointed assistant physician at the Shelby County Asylum for the Insane, vice Dr. James K. Castles, Memphis, deceased.——Dr. Carroll M. Lovell, Dickson, has been appointed local surgeon of the Nashville, Chattanooga & St. Louis Railroad, vice Dr. Edward W. Ridings, deceased.——Dr. Richard M. Little, Dresden, was injured in a runaway accident August 10.

TEXAS.

New College Building.—The new building for the medical department for the Southwestern University, Dallas, will be ready for occupancy early in October.——The Fort Worth Medical University expects to erect a new medical college building, at a cost of from $40,000 to $50,000.

Banquet to Dr. Graves.—The Bexar County Medical Association tendered a farewell banquet to Dr. Marvin L. Graves, retiring superintendent of the Southwestern Insane Asylum, San Antonio, August 10, at which resolutions were adopted regretting his departure to accept the position of chair of theory and practice of medicine in the State University, and commending the wisdom of the State Board of Regents for its selection of Dr. Graves for this position.

Personal.—Dr. Q. Cincinnatus Smith has moved from Austin to San Diego, Cal.——Dr. Aug. D. Ferguson, Kingsville, has moved to Dallas.——Dr. and Mrs. Robert L. Harris, Fulshear, have gone to New York.——Dr. Thomas O. Maxwell, for fifteen years first assistant physician at the State Lunatic Asylum, Austin, has been made superintendent of the Southwestern Insane Asylum, San Antonio, vice Dr. Marvin L. Graves.——Dr. James H. Eastland, Waco, has been appointed first assistant physician at the State Lunatic Asylum, Austin, vice Dr. Maxwell, transferred.——Dr. Willis E. Lowry has succeeded Dr. Shaver as state health officer at Laredo.——Dr. M. G. Pierce, Hookerville, fell, August 6, dislocating his left hip. His advanced age renders the injury more severe.

GENERAL.

Plague in Hawaii.—A death from plague is reported from Waipahu, near Honolulu, August 30.

Personal.—Dr. Jean Guiteras, professor of tropical diseases and pathology in the University of Havana, has been made Dean of the University.

Quarantine Against New Orleans.—The governor of Jamaica has declared quarantine against New Orleans and the republic of Panama (including the Canal Zone), in view of the prevalence of yellow fever in those places.

THE YELLOW FEVER SITUATION.

New Orleans.—The teamsters went on strike last week, interfering materially with sanitary work.——New cases September 11, 38; deaths, none; total cases to September 11, 2,343; total deaths to September 11, 321; death rate, 13.7 per cent.; new cases September 4 to 11, inclusive, 240; deaths September 4 to 11, inclusive, 28.——Capt. B. F. Clayton, quartermaster, U. S. Army, has yellow fever.——An Italian died of yellow fever, his case not having been reported, and his relatives threw his body into Lake Ponchartrain.——The New Orleans *States* keenly scores Dr. Eugene Wasdin, United States Public Health and Marine-Hospital Service, because while in charge at Gulfport, Miss., he failed to find the yellow fever in the little place until it had existed for two or three weeks and until the Alabama officials inspected the town. The *States* asks for the withdrawal of the surgeon.——Assistant Surgeon William C. Rucker, United States Public Health and Marine-Hospital Service, is ill with yellow fever.——The attempt to change annual moving day from September 1 to October 1 had to be abandoned on account of legal obstacles. Arrangements were made, however, for proper fumigation of all premises where a change of tenants occurred.——The United States Public Health and Marine-Hospital Service estimates that, comparing the epidemics of 1878 and 1905 up to September 5, modern methods have saved New Orleans at least a million dollars.——The New Orleans Health Association has become a permanent organization.——Fumigation of houses and educational mass meetings continue throughout the city.——Dr. Charles F. Chassaignac, New Orleans, has volunteered to take charge of the deplorable situation at Tallulah.

Louisiana.—During the week the epidemic has spread slowly. The following is the record of the week, outside New Orleans: Tallulah, 54 cases, 1 death; Lake Providence, 36 cases, no deaths; Patterson, 49 cases, 3 deaths; Kenner, 15 cases, 3 deaths; Hanson City, 23 cases, no deaths; Jefferson, 3 cases, no deaths; St. Rose, 4 cases, 10 deaths; Pecan Grove, no cases, 3 deaths; St. Bernard, 8 cases, no deaths; Venet, 1 case, no deaths; Kinlin, 2 cases, no deaths; Fisher's, 2 cases, no deaths; Amelia, 6 cases, no deaths, Belle Grove, 6 cases, no deaths; Moise, 2 cases, no deaths; Donaldsonville, 3 cases, no deaths; Pointe Celeste, 25 cases, 6 deaths; Woodlawn, 12 cases, 1 death; Greenwood, 1 case, no deaths; Bayou Boeuf, 4 cases, no deaths; Riverside, to September 8, 180 cases, 7 deaths; La Fourche, 4 cases, 2 deaths.——During the week there was grave rioting among the Italians at Patterson, who resisted the efforts of the sanitary officers.——Quarantines continue to be modified.——Up to September 6 there have been 1,075 cases of yellow fever, outside of New Orleans, in Louisiana, Mississippi, Alabama, Georgia, Florida and Missouri. There have been 125 deaths in the same territory, or about 12 per cent.——The Shreveport *Times* relates a case illustrating the hardships of local quarantines. A medical student of Shreveport, going home from New Orleans, was stopped at the bridge into the town and turned back. He got off the return train at Dubberly, Miss., where he was told it would not be safe to remain after dark. He walked to Sibley, another small town, where he was told to move on. He left that place in a livery rig. After a day or two more he arrived at Bossier City, near Shreveport, where he had a talk with Dr. E. Edgar Schumpert of the local board of health, who refused him admittance to the detention camp, as there was one at Bossier. At the Bossier camp Dr. Coleman told him that as he was not a resident of Bossier he had just one hour to leave the town. There the story ended.——At Tallulah the infection is widespread. Dr. George H. Tichenor, Jr., New Orleans, in charge there, reported that he could not obtain public support for the necessary sanitary measures, and asked to be relieved. At last reports Dr. Charles F. Chassaignac of New Orleans had volunteered to take charge.

Other States.

Alabama.—A new relay camp has been established at Flomaton for the inspection and detention of passengers from Pensacola, Fla.

Arkansas.—In addition to the four members of the state board of health last week reported as having resigned, Dr. William Jackson, Jonesboro, has resigned later. Governor Davis has appointed the following new members: Drs. Joseph P. Runyan, president, Little Rock; Dr. Joseph P. Sheppard, secretary, Little Rock, and Dr. Robert A. Hilton, Eldorado. Later he added Dr. John R. Dibrell, Little Rock. The new board of health promptly declared absolute quarantine against Mississippi and Louisiana, even proclaiming: "No certificates recognized from either of these states." It declared that, as rapidly as possible, all four boundaries of the state would be guarded. Freight from the infected states will not be allowed to come in until fumigating stations have been established at the expense of the railroads. The railroads, furthermore, were ordered to maintain detention camps at all points where they cross the boundary. The new board then turned its attention toward persuading the various quarantined towns in Arkansas to abandon their restrictions, trusting entirely to the state quarantine. The Little Rock *Gazette* severely criticized the action of Governor Davis in refusing permission for a surgeon of the United States Public Health and Marine-Hospital Service to pass on a special train through a small stretch of Arkansas territory, even as an act of charity to a suffering community in Louisiana. Arkansas citizens keenly feel the disgrace of their state.——Pine Bluff has raised its local quarantine.——From Mammoth Springs there comes complaint that the militia, as quarantine guards, held a fast mail train at Thayer, Mo., for two hours, while the passengers were made to purchase health certificates at $1.25 each. Those who could not pay were put off the train, according to the Little Rock *Democrat*.——The Rock Island Railway has put in a fumigating plant at Bridge Junction, opposite Memphis.

Florida.—Two new cases were reported from Pensacola on September 5, two the following day, two on the 7th and on the 8th, 11 new cases and one death.——Dr. Stephen M. Gonzalez, in an interview in a local paper, said there was no yellow fever in Pensacola and that physicians were reporting it only for purposes of graft. He was arrested, tried and sentenced to 30 days in jail, sentence being suspended during good behavior.——Many new suspicious cases are under investigation.

Georgia.—On September 2 a man, recently arrived from Pensacola, Fla., developed yellow fever and was properly isolated, but died 3 days later.——By a vote of 5 to 3 the city board of health of Atlanta refused to quarantine against infected points. The medical members were reported as voting for quarantine.——A number of Georgia towns quarantined against Atlanta, and the State Board of Health had previously passed a resolution demanding that Atlanta quarantine against infected points. There are said to be 7,000 refugees in Atlanta.——On September 7 the State Board of Health quarantined the entire state against all infected points.

Indian Territory.—Following the report of a suspicious case at Maysville, the United States Public Health and Marine-Hospital Service has taken charge of the situation at that place.

Mississippi.—Dr. Joseph Goldberger, United States Public Health and Marine-Hospital Service, addressed the physicians of Natchez on methods of meeting the infection.——Having had demonstrated the failure of shotgun quarantine, Natchez is now fumigating and taking other rational measures to check the epidemic.——During the last week Natchez has reported 5 new cases, Gulfport 1, Mississippi City 2, Pearlington 1, Sharkey county 1, Corinth 1, Vicksburg 4 (25 in all), and Fostoria 1.——A negro from Gulfport eluded the quarantine guards at Pass Christian and entered that popular resort. He was later caught, and, it is reported, chained to a tree for two days, exposed to sun and rain and unable to protect himself from mosquitoes. As soon as the federal officers heard of this medieval brutality the negro was liberated and put in the detention hospital.——It is reported yellow fever existed in Vicksburg as far back as July 20. At a meeting of Vicksburg business men, September 1, resolutions of confidence in the mosquito theory and the United States Public Health and Marine-Hospital Service were passed, and the local board of health was asked to modify its quarantine to accord therewith. This was done, and the United States Public Health and Marine-Hospital Service rules were adopted by the board of health, permitting the resumption of freight traffic.——Governor Vardaman, in a proclamation, has so fully accepted the conclusions of medical science that, in justice, some of his statements should be quoted. "The lesson of the Natchez fever ought to be taken well to heart by the people of the entire state. It shows conclusively that it is not enough to rely on quarantine vigilance alone. . . . It emphasizes the necessity of keeping ever closer watch on the internal conditions. . . . I have no hesitancy in expressing my firm conviction that the greatest danger is not so much in admitting the fever to our midst as in overlooking it after the first case has developed. . . . There is little danger when the first case is found and promptly handled in the recognized scientific manner."

Oklahoma.—Oklahoma has quarantined against Arkansas and the Indian Territory.

Tennessee.—Surgeon-General Wyman, United States Public Health and Marine-Hospital Service, replying to Memphis protests against Surgeon White's report of probable yellow fever in Memphis, wired to the state health officer as follows: "The report from yourself and from Secretary Hunter of the Mississippi state board is accepted here. I am satisfied with regard to the situation at Memphis as vouched for by yourself, Governor Vardaman and Secretary Hunter."——The State Board of Health has arranged for funds sufficient to maintain the quarantine until the coming of frost.

Texas.—State Health Officer Tabor addressed the McLennan County Medical Society on September 12.——Texas has quarantined against Memphis.——Galveston banks cashed the warrants necessary to keep the State Health Office in the necessary funds.

CANADA.

Winnipeg General Hospital.—The total number of patients treated in the Winnipeg General Hospital during the week ending August 19 was 326, of whom 201 were men, 81 women and 44 children; 60 out-patients were also treated.

Personal.—Dr. Allan Kinghorn, one of the house surgeons of the Toronto General Hospital, has been awarded the Johnston colonial scholarship in the University of Liverpool. He will take up original pathologic work, and succeeds a Canadian who held the scholarship last year.——Dr. J. Edwards of Grand Rapids, Mich., is visiting in Winnipeg.

Epidemic of Dysentery in Dawson.—A serious epidemic of dysentery is prevailing in Dawson and other points in the Klondike valley. Governor McInnes has convened a conference of the medical men of Dawson and outlying districts to ascertain, if possible, the cause of the disease and to inaugurate efforts to stay its ravages. Adults and children alike are suddenly prostrated with the disease, and numerous deaths have occurred.

Asylum Changes in Ontario.—Dr. Daniel Clark, for many years superintendent of the Toronto Asylum for the Insane, has resigned and has been succeeded by Dr. Charles K. Clarke, superintendent of the Kingston Asylum, who, in turn, is succeeded by Dr. E. Ryan, associate professor of clinical medicine in Queen's University. Dr. Charles E. Hickey, Morrisburg, Ont., has been appointed medical superintendent of the Coburg Asylum, replacing Dr. E. McNichol, who has been retired. Dr. John Williams, Lisle, Ont., has been appointed medical superintendent of the Asylum for Epileptics at Woodstock, Ont.

Canadian Medical Association.—The thirty-eighth annual meeting of the Canadian Medical Association was held at Halifax, August 22-24, and proved one of the best meetings in the history of the organization. The annual presidential address was delivered by Mr. John Stewart, M.B., Halifax; the address in surgery by Mr. Francis Caird, Edinburgh; the address in gynecology by Dr. Howard A. Kelly, Baltimore; the address in ophthalmology by Dr. J. W. Stirling, Montreal, and the address in medicine by Dr. D. A. Campbell, Halifax. The most important matter dealt with was the appointment of a special committee on reorganization, with Dr. A. McPhedran of Toronto as chairman. It was decided to meet in Toronto in 1906 at the same time as the meeting of the British Medical Association. The following officers were elected: President, Dr. Alexander McPhedran, Toronto; general secretary, Dr. George Elliott, Toronto; treasurer, Dr. H. Beaumont Small, Ottawa.

FOREIGN.

Esmarch Memorial.—The small town of Tönning, in Schleswig, Germany, was the scene August 6 of honors paid to F. von Esmarch, its famous son, when his statue was unveiled there. The municipality long ago placed a tablet on the house where he was born in 1823. The statue is more than life size and is a fine portrait of the great surgeon. It was erected by subscription, thousands wishing to show their appreciation of Esmarch's achievements in the systematic organization of first aid to the injured. It is not often that a scientific man is thus honored during his lifetime, but it is still less frequent for an untitled medical man to be the uncle by marriage of the reigning emperor of Germany. Esmarch married the Princess Henrietta of Schleswig-Holstein in 1872, one year before he published his views on the "Artificial Expulsion of Blood for Operations," describing the now familiar "Esmarch bandage."

Cholera in Germany.—It is reported by cable from Berlin that an official bulletin, issued September 8, announces that 19 new cases of cholera and 6 deaths occurred in the cholera-infected districts during the previous twenty-four hours. This makes a total of 123 cases and 39 deaths in the present epidemic. Berlin is placarded with posters warning householders to see that their premises are kept clean and the garbage properly disposed of, as cholera exists in eastern Prussia and communication with the affected districts can not be cut off. It is stated in one of the Berlin papers that some of the Berlin wholesale houses have sent circulars to their customers in infected towns instructing them not to communicate by mail with Berlin because of the danger of infection in the receipt of letters. It is also reported that cholera has broken out in Hamburg far from the points visited by Russian emigrants. An epidemic is feared, but it is being met by what is, perhaps, the most systematic preventive campaign ever undertaken. A sort of sanitary state of siege exists in the district that now extends from the river Oder northwestward to the Russian border, about 250 miles, and from Danzig to south of Posen, about 150 miles. But it is a state of siege in which all the inhabitants are auxiliaries of the medical authorities, and the only enemy is the terrifying cholera bacillus. The medical authorities are disseminating information by red placards, newspaper cautions and sanitary leaflets. Sanitary motor-boats patrol every stream, investigating river craft, seeing that waterside places and resorts are closed, and visiting the cholera stations established at intervals along the rivers. Every physician in the region is, in a sense, the agent of the Medical Council of War, which sits in Berlin. The commander-in-chief is Dr. A. Gaffky, and his special staff of 200 is being constantly increased. Conductors on the state railways are being taught the symptoms of cholera so as to be able to decide, when a person is sick on a train, whether the patient should be placed in a compartment by himself until a large town is reached where he can be sent off to a cholera station. Orders have been given to all employes who sell tickets or receive money from the public to disinfect their hands as often as possible. Dr. Fairfax Irwin, the surgeon in command of the Marine-Hospital Service at Philadelphia, has been ordered to Hamburg to study the cholera situation. He will be joined in Germany by Passed Assistant Surgeon McLaughlin, who is now stationed at Naples. Vigilant precautions are being taken at all the ports of entry of immigrants in this country. The cable and other reports speak of the epidemic in "West Prussia." This does not mean western Prussia, but the district of "West Prussia," bordering on Russia and the Baltic, in the northeastern part of the country.

Medical Consultant to the Muncipality.—As long ago as 1902 the local medical society of Cologne, Germany, petitioned the city council to appoint an "*arztlichen Beigeordneten*" to take charge of the matters for which municipal authorities are in the habit of asking the advice of physicians, or of putting through without any medical suggestions. Extraordinary expert knowledge and skill are required to deal properly with these matters, and the city should have a consultant constantly in its service. The authorities dismissed the appeal of the medical society at that time, but took it up again last year on the renewed solicitation of the society, and have finally created the office of a medical *Beigeordneten*, the first of its kind in any German city. His duties are defined as: 1, Suggestions for improved hygiene in all departments of municipal activity; 2, dwellings and health police, delivering of medical certificates, chairmanship of board of health and of board of oversight of police and dwellings; 3, vaccination; 4, supervision of health in the schools, contagious diseases among scholars and teachers, medical school inspectors; 5, responsibility for imposition of sentences; 6, oversight of food adulteration commission; 7, oversight of schools, hospitals and other public buildings from a hygienic standpoint; 8, membership on boards in charge of orphan asylums, hospitals, disinfection service, bacteriologic laboratory and free dispensaries; 9, member of school deputation, member of commission for meat, market and pure food inspection; 10, public baths, with membership in board in charge; 11, member of boards of vital statistics and medical statistics; 12, medical examination of government employes when taken into the service or granted leave of absence or pensioned. The local medical society is jubilant over its success in the creation of this new post. It regards it as most important progress. Medical skill and knowledge are here diverted into a new field which, when filled by a physician of exceptional training in hygiene and general matters, can not fail to be of the greatest benefit for the public welfare. The secretary of the medical society, in his annual report, comments further to the effect that "this enlarging of the sphere of medical activity will compel the profession more and more to look up, over and beyond the narrow confines of purely medical matters to the grander tasks of the community and of the state. For these the physician—perhaps more than the members of any other profession—is peculiarly fitted by his general and special training. Every physician now should strive to perfect himself more and more in general training, and to work with the greatest perseverance to help in solving the questions that confront the community and the state. This grand aim must not be obscured," he adds, "by the recent efforts of the authorities to aid in perfecting the various medical specialties." The *Münch. med. Wochft.* states that Dr. Krautwurst, hitherto *Kreisarzt* for the Cologne district, has been appointed to the position.

New Prussian Law in Regard to Communicable Diseases.—The text of the new and long anticipated law is given in the *Deutsche med. Wochft.* for July 20 and 27. It is evidently a compromise measure. The original bill required compulsory declaration of cases of tuberculosis and of venereal diseases, but this was amended to declaration of cases of death from tuberculosis. Declaration of cases of venereal disease was first amended to read "in military circles," and then the clause was finally dropped altogether. The law is in eight sections. The first contains the regulations in regard to compulsory declaration of cases and deaths. According to previous laws this was required only for six diseases: leprosy, cholera, spotted typhus, yellow fever, plague and smallpox, but the present law adds 16 to the list; diphtheria, epidemic cerebrospinal meningitis, puerperal fever, trachoma, relapsing fever, dysentery, scarlet fever, typhoid, anthrax, glanders, hydrophobia and bites from rabid or suspected animals, poisoning from meat, fish or sausages, and trichinosis. The declaration must be made within twenty-four hours after learning of the case, the deposition to be made to the police authorities. Also every death from tuberculosis. The physician called to the case is held responsible for the declaration, otherwise the head of the household, the person taking care of the sick one, the householder and the official verifying the disease. The second section is devoted to the determination of the disease. If the sick person is in the care of a physician, the officials wishing to ascertain the facts in the case are not allowed to enter if the attending physician fears injury to the health or life of the patient from their entrance. Opportunity for objection should be given the attending physician before the officials enter. In case of puerperal fever or suspicion thereof, the officials must obtain permission from the head of the household before they can enter. On suspicion of typhoid or glanders, postmortem examination may be required if the attending physician regards it as necessary to complete the diagnosis. In case of diphtheria, trachoma and scarlet fever the local police authorities are required to determine the disease only in the first few cases, and only when they have not been already declared by a physician. The authorities are empowered to extend these regulations to include other diseases when they assume an epidemic form. The third section of the law is devoted to prophylactic measures which are defined in detail for each disease, leaving nothing to the judgment of the local authorities. In respect to diphtheria, compulsory isolation is required, but children need not be taken to a hospital or other place of isolation against the wishes of the parents if the attending physician or the medical official thinks that sufficient isolation can be realized at home. In puerperal fever the midwife or obstetric nurse is to be informed of the presence of the disease at once, and she must refrain from attendance on any other childbirth during and for eight days after leaving the first case, and then only after thorough disinfection of her body, clothing and instruments, under instructions from the medical official, who is empowered to shorten the interval at his judgment. In typhoid fever, besides the usual measures of isolation, declaration of case and location, and disinfection, all public gatherings may be forbidden if the disease assumes an epidemic character. Six months' imprisonment or a fine of $150 is the penalty for using or allowing others to use articles for which disinfection is required before the disinfection has been done. The penalty for disregard of the measure requiring compulsory declaration by the physician or other responsible person is arrest or a fine of about $38, which is also imposed for preventing the enforcement of the official measures or the entrance of the medical officials. One section of the law defines the details of indemnification of parties for articles destroyed or injured by the officials in their prophylactic duties. The claim for damages must be presented to the local police authorities within a month, although further delay may be granted under certain circumstances. Articles to be destroyed or injured by the officials must be appraised by experts before their destruction.

Marriages

A. E. Carney, M.D., Owasa, Iowa, at Asbury Park, N. J., August 23.

Arthur G. Neighbor, M.D., to Miss Minnie La Grue, both of Fowler, Ind.

Phil R. Polk, M.D., to Miss Hattie Hamilton, both of Silver Creek, Miss.

W. H. Steele, M.D., Hastings, Neb., to Miss Alice Kimball of Chicago, August 27.

Bert N. Estabrook, M.D., to Miss Olive M. Bast, both of Detroit, Mich., August 29.

Carl O. Imoberstag, M.D., to Miss Mabel E. Sperber, both of Toledo, Ohio, August 30.

Earnest Empey, M.D., Billings, Mont., to Miss Hallie Spear of Omaha, August 30.

Guy H. Hutchins, M.D., Bowdoinham, Maine, to Miss Hortense Bradford, September 6.

George A. Pugh, M.D., Kenosha, Wis., to Miss Nellie Ball of Stratford, Ont., August 29.

Weston H. Rice, M.D., to Miss N. Nelle Hopkins, both of Burlington, Vt., September 2.

W. S. Polk, M.D., Oakvale, Miss., to Miss Beulah Williamson of Goss, Miss., at Society Hill.

Fred Roderick Dew, M.D., to Miss Bertha Blanche Young, both of Salem, W. Va., August 30.

Hedlie V. Tweedie, M.D., Baltimore, to Miss Edith D. Hutson, at Rawlings, Md., September 6.

George M. Decherd, M.D., Austin, Texas, to Miss Pansy Green of Granger, Texas, August 30.

Charles Martin Wood, M.D., Decatur, Ill., to Miss Edith Loose of Illiopolis, Ill., September 12.

Blanchard B. Pettijohn, M.D., Indianapolis, to Miss Zelda Klingler of Zionsville, Ind., August 30.

Pern Jefferson Bidwell, M.D., Toledo, Ohio, to Miss Virginia Moyer of Colfax, Ohio, August 29.

T. Lee Van Giesen, M.D., New Castle, Pa., to Miss Mabel E. Manbeck of Lebanon, Pa., August 30.

Maurice M. Reichard, M.D., Philadelphia, to Miss Frieda Deutsch in New York City, September 3.

William A. Briggs, M.D., Bowling Green, Ky., to Miss Ida Mai Harrison of Alton, Ind., September 6.

Byron G. Monkman, M.D., Portland, Ore., to Miss Nellie M. Sauer of Bay City, Mich., September 1.

Mont R. Farrar, M.D., Greensboro, N. C., to Miss Annie Pleasants of Dilworth, N. C., September 14.

George Gill Mulheron, M.D., Nut Bush, Tenn., to Miss Lillie Mai Walker of Durhamville, Tenn., September 6.

Leroy Philip Kuhn, M.D., Palmyra, Wis., to Miss Bessie Margaret Patterson of Chicago, September 9.

Julius W. Boiarsky, M.D., Huntington, W. Va., to Miss Florence Greenwold of Cincinnati, September 5.

Ralph K. Keene, M.D., Wessington Springs, S. D., to Miss Wilma H. Rouse of Lakefield, Minn., August 29.

Frank Foulk, M.D., Des Moines, Iowa, to Miss Wallace of Independence, Iowa, at Des Moines, September 3.

William A. Williams, M.D., to Miss Edna Z. Bacon, both of Hurne, Mo., at Kansas City, Mo., September 6.

Fred Albert Simmons, M.D., Brockton, Mass., to Miss Geneva A. Cobb of Providence, R. I., September 6.

Edward C. Koenig, M.D., North Tonawanda, N. Y., to Caroline M. Osborne, M.D., at Phelps, N. Y., August 30.

P. Elwood Stigers, M.D., Hancock, Md., to Miss C. Virginia Barker of West Virginia, at Ellicott City, Md., August 21.

Benjamin Trowbridge Tilton, M.D., New York City, to Miss Anna Billings Griggs of Tacoma, Wash., September 14.

Patience S. Bordeau, M.D., Grand Rapids, Mich., and Henry N. Fisco of New York City, at Grand Rapids, September 6.

Clarence Philip Obenschain, M.D., Kerr's Creek, Va., to Miss Alice Virginia Kirkpatrick at Alone, Va., September 6.

Perry J. Payne, M.D., Jamestown, Pa., to Miss Jean L. Veach of New Castle, Pa., at Chautauqua, N. Y., August 30.

Neil Campbell Monroe, M.D., Rogers City, Mich., to Miss Bessie Kennedy Whiteley of Millersburg, Mich., September 6.

Arthur Preston Clark, M.D., New Hartford, N. Y., to Miss Mabel Angeline Robinson of Watertown, N. Y., August 30.

Blanche Rosalie Slaughter, M.D., Washington, D. C., and Mr. Baxter Morton of New York City, at Lynchburg, Va., September 6.

J. Scott McLeod, M.D., Boston, Mass., to Miss Minnie M. Detterick of Las Vegas, New Mexico, at New York City, September 9.

Deaths

Ephraim J. McCallum, M.D. Jefferson Medical College, Philadelphia, 1853, the oldest practitioner of Seneca County, Ohio, for many years a member of the American Medical Association and the Ohio State Medical Association; an honorary member of the Northwestern Ohio and Seneca County medical societies, beloved and esteemed by all, died at his home in Tiffin, Ohio, September 7, from heart disease, after an illness of four days, aged 85. A year ago the entire medical fraternity of the county celebrated the golden anniversary of Dr. McCallum's entry into practice and presented him with a silver loving-cup.

Milton H. Hardy, M.D. New York University, New York City, 1887, a member of the *American Medical Association*, and of the Salt Lake County *Medical Society*; *superintendent* of the State Mental Hospital, Provo, Utah, from 1896 to June, 1905; a prominent Mormon alienist; formerly superintendent of schools of Utah County, and later territorial superintendent of schools, died at his home in Provo August 23 from valvular heart disease, after a long illness, aged 60.

Siegfried Martus, M.D. New York University, New York City, 1889, New York City, member of New York County Medical Society, New York County Medical Association, Harlem Medical Association, German Medical Society, for fourteen years on the staff of Mt. Sinai Hospital, and medical adviser of the Hebrew Technical Institute, died at New York Hospital a short time after an operation for appendicitis, August 31, aged 43.

John Milton Davies, M.D. Penn Medical University, Philadelphia, 1854, said to have been the oldest practitioner in western Pennsylvania, an assistant surgeon and surgeon of the Ninth New Jersey Volunteer Infantry, post surgeon at Newberne, N. C., and acting mayor of that city during the Civil War, city physician of Erie, Pa., in 1872 and 1873, died at his home in Warren, Pa., September 5, from senile debility, aged 77.

Simon Mower Whistler, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1866, acting assistant surgeon in the Army during the Civil War; a member of the Medical Society of the State of Pennsylvania, died at his home in Harrisburg, August 17, *after an illness of six* weeks, aged 63.

***Jacob S. Ammon*, M.D.** Department of Medicine of the University of Pennsylvania, Philadelphia, 1868, *sometime* vice-president of the Banks County Medical Society; surgeon during the Civil War, died at his home in Reading, Pa., September 5, after an illness of more than a year, aged 68.

William M. Late, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1855, of Bridgeport, Harrison County, W. Va., died at the home of his daughter in Bordentown, N. J., September 5, after an illness of two weeks, aged 72.

Samuel H. Fee, M.D. Faculty of Medicine of Queen's University, Kingston, Ont., 1862; health officer of Kingston; formerly in the United States Army, and an alderman of Kingston, shot himself while suffering from melancholia August 31, aged 65.

Frederick William Billart, M.D. (Years of Practice) Indiana, 1897, for more than half a century a practitioner of Indiana, died from intestinal obstruction at his home in Chrisney, Ind., September 4, after an illness of two days, aged 73.

Joseph H. Green, M.D. Medical Department of the University of Cincinnati, 1860, one of the oldest practitioners of Miami County, Ohio; a surgeon in the Civil War, died at his home in Troy, September 6, aged 72.

George E. Carey, M.D. Medical Department of Western Reserve University, Cleveland, Ohio, 1885, of Salina, Pa., died at the home of his mother in Maple Shade, Pa., August 26, after an illness of four years, aged 47.

David Arthur Titus, M.D. Michigan College of Medicine and Surgery, Detroit, 1892, of Detroit, Mich., died at Port Arthur, Mich., August 15, from brain abscess following typhoid fever, after a short illness, aged 35.

James K. Castles, M.D. Memphis (Tenn.) Hospital College, 1900, assistant physician at the Shelby County Poor and Insane Asylum, died at his home in the First Civil District of Shelby County, August 15.

Henry Utley, M.D. New York University, New York City, 1899, surgeon of the Seventy-fifth Illinois Volunteer Infantry during the Civil War, died at the home of his son in Sterling, Ill., April 27, aged 82.

Charles Edwin Parker, M.D. University of Vermont Medical Department, Burlington, 1889, member of the Massachusetts Medical Society, died in Princeton, Mass., July 10, from carcinoma, aged 41.

Neal Hardy, M.D. University of Wooster Medical Department, Cleveland, Ohio, 1873, of Canton, Ohio, died suddenly at Hicksville, Ohio, August 28, from heart disease, aged 58.

William W. Bass, M.D. Berkshire Medical College, Pittsfield, Mass., 1835, surgeon during the Civil War, died at his home in Dorchester, Boston, July 21, after a long illness, aged 95.

William B. Cooper, M.D. Medical College of Ohio, Cincinnati, 1860, died at his home in Kokomo, Ind., from acute nephritis, September 6, after an illness of only two days, aged 70.

John D. Finnegan, M.D. University of Vermont Medical Department, Burlington, 1893, formerly of Ogdensburg, N. Y., died at his home in Moira, N. Y., August 26, aged 48.

John S. Curtis, M.D. Medical College of Ohio, Cincinnati, 1878, of Washington Court House, Ohio, died near Sedalia, Ohio, August 20, from heart disease, aged 55.

George W. Duncan, M.D. University of Louisville Medical Department, died from cancer of the face at his home in Franklin, Ky., September 8, aged 80 years.

John B. Gilman, M.D. University of Vermont Medical Department, Burlington, 1884, died at his home in West Pawlet, Vt., September 1, after a short illness.

Samuel T. Dickinson, M.D. Jefferson Medical College, Philadelphia, 1849, died at his home near Milford, Va., September 5, after a lingering illness, aged 76.

William E. Tarbell, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1868, died at his home in Athens, Maine, August 18, aged about 60.

E. H. Yancey, M.D. Macon, Ga., 1869, surgeon in the Confederate service during the Civil War, died at his home in Covington, Ga., July 1, aged 70.

***Horatio Woodbury*, M.D.** *Medical School of Maine at Bowdoin* College, Brunswick, 1882, died at his home in South Paris, Maine, July 9.

George Rice, M.D. *Medical Institution of Yale College*, New Haven, Conn., died at his home in South Framingham, Mass., April 18, aged 67.

Clement F. Ellerbrock, M.D. Baltimore Medical College, 1900, died at Deming, N. M., from tuberculosis September 2, aged 27.

Charles F. Dilley, M.D. Rush Medical College, Chicago, 1863, died at his home in Spickard, Mo., September 3, aged about 75.

George Henry, M.D. Long Island College Hospital, Brooklyn, 1860, died in Denver, Colo., April 23 from heart disease.

James A. Francisco, M.D. (Examination, Ohio), died recently at his home in Port Clinton, Ohio.

***Carolyn Dewey Beebe*, M.D.** Colorado, 1903, *died in Denver*, Colo., March 13, aged 39.

Queries and Minor Notes

THE USE OF CARBOLIZED SPONGE TENTS.

Grand Rapids, Mich., July 25, 1905.

To the Editor:—If at all, in what uterine derangements would you consider it legitimate and good treatment, to use carbolized sponge tents? A. B.

Answer.—The ease with which the aseptic dilator may be substituted for any legitimate purpose for which the sponge tent was formerly used makes the use of the latter no longer justifiable or desirable. Many prominent gynecologists and obstetricians never employ them. The writer of a well-known textbook on gynecology says: "I would limit their employment altogether to obstetric cases," while an examination of a number of recent authoritative text-books on obstetrics reveals no mention of sponge tents. Lest a biased opinion be given the dealers in surgical supplies were consulted and asked: "How often do you have a call for sponge tents?"

No. 1: "Almost every day."

No. 2: "We almost never have a call for sponge tents."

No. 3: "Frequently."

"Who is ordering them, city obstetricians and gynecologists or country practitioners?"

No. 1: "I might say neither; the call comes almost entirely from midwives. Some buy from four to six dozen at a time."

No. 2 said he had no midwife practice.

No. 3: "Our call comes almost entirely from the country."

The reader may judge for himself the use to which these articles are put. No efforts were made in any case to have the tents kept surgically clean.

An aseptic non-dilatable smooth foreign body may do damage if left in the uterus, a rough dilatable sponge tent whose fingers will insinuate themselves into the endometrium will do much more harm, and such a structure, septic as a sponge tent must always be considered, has dangers in its use beyond our power to estimate. It should be considered a relic of bygone days and important only in the history of the pre-aseptic period.

BOOKS ON MICROSCOPIC DIAGNOSIS.

Sylacauga, Ala., Sept. 7, 1905.

To the Editor:—Will you kindly advise me as to the best textbook or compend suited to the use of a busy country doctor who has to do most of his own microscopy. I want a good, practical, abridged text giving each step in the technic clearly and concisely. H. L. Castleman.

Answer.—Cabot's "Clinical Examination of the Blood" ($3.50, Wm. Wood & Co., New York) is excellent on the blood, and so is Ogden's "Clinical Examination of the Urine" ($3.00, W. B. Saunders & Co., Philadelphia), on the urine. Von Jaksch's "Clinical Diagnosis" ($6.50, J. B. Lippincott & Co., Philadelphia) is the most complete book on the whole subject, but is probably too technical. Simon's "Manual of Clinical Diagnosis" ($4.00, Lea Brothers & Co., Philadelphia) is probably best adapted to our correspondent's needs.

State Boards of Registration

COMING EXAMINATIONS.

Central District Indian Territory Board of Medical Examiners, South McAlester, October 2. Secretary, W. B. Caldwell, Hugo.

Utah State Board of Medical Examiners, Salt Lake City, October 2. Secretary, R. W. Fisher, Salt Lake City.

Board of Medical Examiners of Arizona, Phoenix, October 2-3. Secretary, A. Martin, Phoenix.

Idaho State Board of Medical Examiners, Boise, October 3. Secretary, J. L. Conant, Jr., Genesee.

Indiana Board Medical Registration and Examination, State House, Indianapolis, October 3. Secretary, W. T. Gott, Crawfordsville.

Board of Medical Examiners of Montana, The Capitol, Helena, October 3. Secretary, W. C. Riddell, Helena.

North Dakota State Medical Examining Board, Grand Forks, October 3. Secretary, H. M. Wheeler, Grand Forks.

Minnesota State Board of Medical Examiners, Old Capitol Building, St. Paul, October 3-5. Secretary, C. J. Ringnell, Minneapolis.

Rhode Island State Board of Health, State House, Providence, October 5-6. Secretary, G. T. Swarts, Providence.

Regular Board of Medical Examiners of Georgia, The Capitol, Atlanta, October 9. Secretary, F. D. Paterson, Cuthbert.

Michigan State Board of Registration in Medicine, Capitol Building, Lansing, October 10. Secretary, B. D. Harison, Sault Ste. Marie.

State Medical Board of the Arkansas Medical Society, Little Rock, October 10. Secretary, J. P. Runyan, Little Rock.

State Board of Medical Registration of Vermont, Y. M. C. A. Hall, Burlington, October 10-12. Secretary, W. S. Naya, Underhill.

Kansas State Board of Medical Registration and Examination, State House, Topeka, October 10-11. Secretary, G. F. Johnston, Lakin.

Board of Medical Supervisors of Washington, D. C., Washington, D. C., October 12. Secretary, W. C. Woodward, Washington, D. C.

Board of Medical Examiners of State of Texas, San Antonio, October 17. Secretary, T. T. Jackson, San Antonio.

State Board of Medical Examiners of New Jersey, Trenton, October 17-18. Secretary, E. L. B. Godfrey, Camden.

State Board of Health of Illinois, The Great Northern Hotel, Chicago, October 18. Secretary, J. A. Egan, Springfield.

Louisiana State Board, New Orleans, October 20-21. Secretary, F. A. Larue, New Orleans.

Washington July Report.—Dr. C. W. Sharples, secretary of the Washington State Medical Examining Board, reports the written examination held at Seattle, July 5-7, 1905. The number of subjects examined in was 17; total number of questions asked, 100; percentage required to pass, 75, and 70 in case of applicants who graduated ten years previous. The total number of candidates examined was 94, of whom 77 passed and 17 failed. The following colleges were represented:

Goldberger, Joseph, P. A. surgeon, to proceed to Memphis, Tenn., for special temporary duty.

Goldberger, Joseph, P. A. surgeon, to proceed to Bainbridge, Ga., for special temporary duty.

Trotter, F. E., P. A. surgeon, to proceed to Victoria, B. C., for special temporary duty.

[illegible] surgeon, relieved from duty in office of [illegible] ly, and assigned in office of American [illegible] y.

[illegible] to proceed from Naples, Italy, to Trieste for special temporary duty.

Ashford, F. A., asst.-surgeon, relieved from duty at Ellis Island and directed to proceed to New Orleans, La., *and to report to* Surgeon J. H. White for special temporary duty.

Roehrig, A. M., pharmacist, to represent the service at meeting of the American Pharmaceutical Association at Atlantic City, N. J., September 4-9.

Richardson, S. W., pharmacist, to proceed to New Orleans and report to Surgeon J. H. White for special temporary duty.

APPOINTMENTS.

Dr. Marshall C. Guthrie of North Carolina, commissioned as assistant surgeon, Public Health and Marine-Hospital Service.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from August 19 to September 8:

SMALLPOX—UNITED STATES.

Louisiana: New Orleans, August 19-26, 1 case.
Michigan: Grand Rapids, August 19-26, 2 cases.

Ohio: Toledo, August 12-19, 1 case.
Tennessee: Memphis, August 19-26, 2 cases.
Wisconsin: Appleton, August 19-26, 2 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, July 1-8, 1 case.

SMALLPOX—FOREIGN.

Brazil: Bahia, July 29-August 5, 1 death; Rio de Janeiro, July 23-August 6, 18 cases, 5 deaths.
Chile: Valparaiso, to August 9, 3,553 cases, 836 deaths.
China: Niuchwang, July 22, 1 case.
France: Lyon, August 5-12, 1 death; Paris, August 5-19, 76 cases, 11 deaths.
Great Britain: Cardiff, Aug. 12-19, 1 case; Liverpool, 1 case; London, July 29-Aug. 5, 3 cases.
India: Bombay, July 25-August 8, 6 deaths; Calcutta, July 22-29, 3 deaths; Madras, July 22-28, 3 deaths.
Italy: Catania, August 17-24, 1 death.
Russia: Moscow, July 22-August 12, 13 cases, 6 deaths; Odessa, August 5-19, 11 cases, 3 deaths; St. Petersburg, July 29-August 5, 3 cases 1 death.
Spain: Barcelona, August 10-20, 1 death.

YELLOW FEVER—UNITED STATES.

Florida: Pensacola, August 29, 3 cases.
Georgia: Atlanta, September 2, 1 case, imported.
Indian Territory: Mayville, September 1, 1 case, doubtful.
Louisiana: Acadia Parish, to August 17, 1 case; Ascension Parish, August 14-September 3, 21 cases; Assumption Parish, August 26-September 3, 6 cases; East Carroll Parish, August 14-September 4, 36 cases, 1 death; Iberville Parish, to August 31, 15 cases, 5 deaths; Jefferson Parish, to September 3, 149 cases, 14 deaths; Lafayette Parish, August 15-September 4, 2 cases; Lafourche Parish, to September 3, 331 cases, 31 deaths; Madison Parish, August 14-September 4, 9 cases; Orleans Parish, July 21-September 4, 2,075 cases, 292 deaths; Plaquemines Parish, to September 3, 23 cases, 2 deaths; Rapides Parish, August 15-September 3, 7 cases; St. Bernard Parish, to Sept. 3, 7 cases, 1 death; St. Charles Parish, 73 cases, 6 deaths; St. James Parish, 4 cases; St. John the Baptist Parish, 55 cases, 7 deaths; St. Mary Parish, 342 cases, 9 deaths; St. Tammany Parish, to August 22, 2 cases; Terrebonne Parish, to September 3, 66 cases, 3 deaths.
Mississippi: Gu[illegible] 22-August 19, 53 cases, 1 death, on vessel; [illegible] 8, 1 case, diagnosis proved not yellow fever; [illegible] 1 case; Mississippi City, August 22-September 4, 31 cases; Natchez, to August 30, 15 cases; North Gulfport, August 15-September 4, 32 cases; Pearlington, September 1, 2 cases; Vicksburg, August 30, 2 cases.
New York: New York Quarantine, August 1-12, 1 death, from S. S. *Advance*, from Colon.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, July 22-August 5, 16 cases, 6 deaths.
Mexico: Tezonapa, Aug. 20-26, 3 cases; Tierra Blanca, August 13-26, 1 case, 2 deaths; Vera Cruz, 5 cases.
Nicaragua: Leon, August 8, present; Managua, present.
Peru: Lima, August 12, 1 case, imported.
Panama: Bocas del Toro: August 11-18, 1 case; Colon, July 31-August 12, 6 cases, 2 deaths; Panama, 8 cases, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, August 26, present.

CHOLERA—FOREIGN.

Germany: Hamburg, August 29-September 5, 2 cases, 1 death, first case imported.
India: Bombay, July 25-August 8, 2 deaths; Calcutta, July 22-29, 26 deaths; Madras, July 22-28, 145 deaths.

PLAGUE—INSULAR.

Hawaii: Waipahu, August 30, 1 death.
Philippine Islands: Manila, July 1-8, 3 cases, 2 deaths.

PLAGUE—FOREIGN.

Argentina: Santiago del Estero, July 20, recrudescence.
Australia: Queensland: Cairns, July 8, 1 case; Ipswich, July 5, 1 case, 1 death; New South Wales: Sydney, July 1-8, 1 case.
Brazil: Rio de Janeiro, July 22-August 5, 4 cases, 2 deaths.
China: Mukden district, July 22, reported.
Egypt: General, July 8-15, 11 cases, 10 deaths.
India: General, June 24-July 8, 4,338 cases, 3,943 deaths; Bombay, July 25-August 8, 102 deaths; Calcutta, July 22-29, 8 deaths; Madras, July 22-28, 1 death.
Japan: Chiba Ken, July 20, 1 death.
Panama: La Roca, August 26, 1 death.
Peru: Lima, July 10-20, 2 cases, 2 deaths.
Siam: Bankok, July 1, present.
Turkey: Beirut, July 17, 1 case, imported.

Coming Society Meetings

American Electro-Therapeutic Association, New York City, September 19-21.

American Association of Obstetricians and Gynecologists, New York City, September 19-25.

American Public Health Association, Boston, September 25-29.

Medical Society of the State of Pennsylvania, Scranton, September 26-28.

Association of Military Surgeons of the United States, Detroit, September 26-28.

Wyoming State Medical Society, Cheyenne, September 27-28.

American Roentgen Ray Society, Baltimore, September 28-30.

Mississippi Valley Medical Association, Indianapolis, October 10-12.

New York State Medical Association, New York City, October 16 19.

American Academy of Medicine, Chicago, November 7-8.

American Dermatologic Association, New York City, December 28-30.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Chronic Nephritis.

Damage done to a kidney can not be repaired is the basis on which Dr. A. C. Morgan, in *Med.-Chir. Jour.*, places his treatment toward prohibiting any advance of pathologic process. The complications which may arise in the course of a chronic interstitial nephritis are the chief causes of death, such as pneumonia, la grippe, cerebral hemorrhage, cardiac dilatation, pericarditis and inflammation of other serous membranes.

Uremia arising in the course of nephritis is a sign of broken compensation of the kidney similar to an incompetent heart. So in the administration of diuretics the same rule should hold good as in the treatment of heart lesions, and these remedies should never be used until actually needed.

Hygienic measures should be enforced in the treatment of chronic nephritis. Flannels should be worn the year round in order to keep the skin active and steady and to protect the patient from sudden changes of weather. If possible, a warm equable climate should be sought in the winter time. Social life should be abandoned and irregular hours of sleep avoided. Cold baths should be prohibited in order to avoid throwing too much work on the kidneys. Hot baths are of value in order to promote skin elimination and thus to relieve the kidneys. Baths may be given in the form of warm packs, Turkish baths, vapor or hot-water baths. Massage is of value when the patient is confined to bed for any reason. Rest in bed is recommended when the albumin is severe or persistent, or when the heart shows signs of weakness, and the patient should be required to remain in bed for ten hours out of the twenty-four to relieve the heart's action and to diminish the general activity. A large amount of water is required to replace the excessive excretion of water and to keep the solids in solution, avoiding, however, excess in this treatment, as the tension may be increased by the ingestion of too much water. Three quarts of water a day is said to be a proper amount. The carbonated waters are recommended to counteract the high acidity of the urine which is usually present. According to Millard, malt liquors are bad, spirits are worse and acid wines are the least harmful.

DIET.

As to diet, the nitrogenous foods must be decreased considerably, as they increase the secretion of urea. However, the diet must not be too much restricted, as the patient's strength must always be maintained. Coffee and tea must be used sparingly and milk used to a marked extent. Meat and gravies must be restricted; oysters may be eaten freely.

SYSTEMIC TREATMENT.

The object to be kept in mind is to inhibit or to arrest the sclerotic and degenerative changes and to overcome the anemia. Potassium iodid, hydriodic acid and mercuric chlorid are the preparations to be used in combating the first conditions, and arsenic and iron to correct the anemia. Iron is an astringent and a tonic, but must not be used, according to this writer, in too large doses, as excessive doses disturb the secretions and lead up to dangers of uremia.

If the conditions are such as to require a decrease in the arterial tension, such as flushing of the face, congestive headaches, vertigo and epistaxis, and if the heart is in good condition, veratrum viride or aconite is recommended over long periods, and glonoin is of service if the heart is weak. A low tensional pulse predisposes to serous effusions and a decrease in the daily elimination from the kidney, thus increasing the dangers of uremia, and this must be overcome. In such conditions digitalis combined with nitroglycerin is recommended.

Whether the fluid in the cavities be an exudate or a transudate it should be disposed of as rapidly as possible. If a transudate is present, increase the tension; if an exudate, absorptives or local applications are of service. If necessary the cavity may be tapped and an adrenalin solution injected which, the author states, prevents further accumulation of the fluid.

Saline cathartics are valuable in getting rid of fluid by absorption.

Counterirritation is of service in the parenchymatous form in which a marked congestion of the kidney is present. Dry or wet cupping over the kidney often relieves the congestion and improves diuresis.

Drowsiness is to be overcome by decreasing and restricting the solid diet, by increasing the fluids and elimination by means of purging, of sweating rather than by diuretics, which may be required later in the course of the disease.

Slight edema may be overcome by bandaging the limbs, rest in bed late in the morning, or rest in the middle of the day. If the edema still progresses other eliminants and diuretics must be employed, and if the limbs become large and the skin tense the skin may be punctured in many places and thus the fluid allowed to escape; in some cases the Southey tubes may be inserted. Erysipelas may be avoided in such procedures by careful attention to asepsis in the dressings.

Persistent vomiting or diarrhea are symptoms of toxemia. The former is relieved by washing out the stomach and the latter by diaphoresis and diuresis, but it should not be checked entirely, as it may bring on uremia.

Pruritus is due ordinarily to urea crystals irritating the skin. Hot baths followed by a 4 per cent. carbolic acid solution applied localy, or the infusion of conium leaves or chloral internally relieve the condition.

UREMIA.

When uremia develops, showing the failure in compensation of the kidney, venesection is indicated to rapidly eliminate the toxins, followed by an injection of the normal salt solution. When convulsions occur such preparations as caffein, scoparius, digitalis and convallaria are useful. If the heart is well compensated and does not enter into the cause of dropsy, the potassium salts, scilla and sweet spirits of niter are recommended to aid the function of the kidney. Asthma is frequently a symptom denoting the presence of a toxemia and disappears with the improvement, by eliminants, of the heart and kidney. Sometimes it is necessary to resort to chloral or morphin hypodermically in small doses, or perhaps to venesection.

Epistaxis sometimes occurs and indicates the necessity of lowering blood pressure.

Diaphoretics are indicated very early in the treatment as promoters of elimination and thus relieving the work of the kidney. They should be employed regularly, depending chiefly on hot water or hot-air baths. As to the medicinal agents as diaphoretics, sweet spirit of niter and liquor ammonia acetatis are preferable, using pilocarpin in emergency cases. Diuretics are of value only when the compensation of the kidney has failed and the urine is scanty and dropsy present. When indicated by poor heart's action and also to assist the kidney, the author recommends a hypodermic injection of morphin, followed the next morning by a hypodermic injection of pilocarpin. The author states that he has never seen any ill-effects follow the use of morphin when given in this way. The operation for stripping off the capsule of the kidney was not discussed by this writer.

Acute Nephritis.

Yeo recommends the following combinations in the treatment of acute Bright's disease:

℞.	Infusi jaborandi (1-45)	℥vi	180
	Syrupi aurantii	ʒv	20

M. Sig.: One tablespoonful every hour or two.

To relieve the anasarca in acute Bright's disease after the early acute symptoms have subsided, the following is recommended:

℞.	Tinct. ferri chloridi	ʒvi	24
	Liq. ammon. acetatis	℥iii	90
	Aquæ chloroformi	℥vi	180

M. Sig.: One tablespoonful in a wineglassful of water every four hours.

As a diuretic in acute Bright's disease he recommends the following:

℞.	Potass. citratis	℥ss	15
	Infusi digitalis	℥ii	60

M. Ft. mistura. Sig.: Two teaspoonfuls in aërated water every three hours.

In the chronic form the following combination is recommended as a diuretic:

℞.	Tinct. digitalis	℥ss	15
	Vini scillæ	℥iss	45
	Spts. etheris nitrosi	℥ii	60

M. Sig.: One teaspoonful in water every three or four hours.

For the general elimination the following is of value:

℞.	Potassii iodidi	gr. xv	1
	Sodii phosphatis	gr. xxx	2
	Sodii chloridi	gr. lxxv	5
	Aquæ q. s. ad	℥xx	600

M. Sig.: The entire amount to be taken in divided doses in the twenty-four hours.

As a tonic and diuretic the following is advised:

℞.	Tinct. ferri chloridi	℥ss	15
	Acidi acetici	ʒss	2
	Liq. ammon. acetatis	℥v	150
	Aquæ	℥ii	60

M. Sig.: One teaspoonful in water three times a day. Or:

℞.	Ferri sulph.		
	Sodii bicarb, āā	gr. lxxv	5
	Ext. taraxici	ʒi	4

M. Ft. pil. No. lx. Sig.: Take three pills night and morning.

As a hydrogogue cathartic the following is of value:

℞.	Potassii tartarati	ʒi-iss	4-6
	Pulv. jalapæ	gr. viii	5
	Pulv. cambogiæ	gr. i	06

M. Ft. chartula No. i. Sig.: To be taken at night and a similar dose the following morning.

To relieve the anasarca the following combination is also recommended by some authorities:

℞.	Potassii acetatis	ʒiiss	10
	Infusi digitalis		
	Infusi juniperi, āā	℥iii	90

M. Sig.: One tablespoonful every two to four hours.

Elaterin is a very efficient preparation to relieve the edema of the lower extremities and the abdominal ascites. It may be given in doses ranging from gr. 1/40 (.001) to gr. 1/20 (.003) and the dose repeated every two hours until a watery evacuation is produced.

Medicolegal

Rights Under Later, of Practitioner Under Former, Law.

The Supreme Court of Idaho holds (State vs. Cooper, 81 Pacific Reporter, 374), that under the provisions of section 5 of what is known as the "Medical Law of 1899," the Board of Medical Examiners are not empowered to call on applicants for a license for their diplomas, who were engaged in the practice of their profession under the law of 1887. Where it is shown that an applicant for a license to practice medicine and surgery was a resident of the state, engaged in the practice of his profession under the provisions of the law of 1887, and had complied with all the provisions of the law of 1899, the court holds that, in case the Board of Medical Examiners refused to issue his license, it was not criminal in him to pursue his profession. It was urged in this case by counsel for the state that the applicant should have resorted to his civil remedy by an appeal from the action of the Board of Medical Examiners to the district court, and there had the action of the board reviewed. It appeared that the board called on him for his medical diploma, which he sent to the board, who thereafter informed him that they did not and would not recognize the institution giving it as one having authority to issue a diploma to a doctor of medicine. The court says that when he received this notice he had the right to appeal from the action of the board, or he could treat their action as an infringement on his rights under the laws of 1887 and 1899. The statute of 1899 did not authorize the board to demand of him his diploma. He had furnished them all that they were entitled to under the law. They could not ignore the plain provisions of the 1899 law, and thereby make a criminal of a citizen of the state engaged in a legal and lawful business. If the Board of Medical Examiners could withhold a license from an applicant in this manner until he could appeal to the courts for redress, making a criminal of him every time he prescribed for or visited a patient, they could not only deprive him of valuable property rights, but ruin him in his profession, and brand him as a criminal. This is neither the spirit nor intent of the law.

Insanity and Expert Evidence.

The Supreme Judicial Court of Massachusetts says, in the homicide case of Commonwealth vs. Johnson, where the only defense offered was the insanity of the defendant at the time of the homicide, that on this issue it was competent for him to show that his ancestors or relatives had been insane, but the order in which the evidence should be introduced was wholly within the discretion of the trial court. A refusal to permit the cross-examination of the government experts on the relative value and reputation of medical authorities who had written on the general subject of insanity, as well as the exclusion of certain hypothetical questions addressed to them, were also discretionary. Nor is error found in the government having been allowed to question each of these experts as to whether he had formed any opinion, from his examinations and investigations and what he had heard in court, as to the mental condition of the defendant on date named, the physical and mental history of his family and himself, on which the questions were founded, having come solely from the defendant's statements, letters, and admissions or from his witnesses, and having been accepted as true, while it further appeared that each of the experts also had seen and examined him. Then, this question having been answered in the affirmative, and an opinion given that he was sane, followed by a similar reply to the further question, "What is your opinion of his sanity now?" the court says that if a question of this character, resting on the assumption of the truth of the evidence of a plaintiff alone, is admissible, which has been held, there is in principle no substantial reason why a medical expert, who has not made an examination of the patient whose physical or mental condition he is called on to determine, but has heard it described by witnesses at the trial, should not answer similar questions without their being hypothetically framed. By this form of examination no injustice is done, for whatever reasons, even to the smallest details, that an expert may have for his opinion, can be fully brought out by cross-examination. But here, as in other matters relating to the general management of trials, much must be left to the judgment of the trial court, which will not be revised unless the course pursued plainly was prejudicial to the legal rights of the defendant. Thus the length of hypothetical questions, or whether the facts assumed are within the hypothesis on which it is claimed the case rests, or whether a witness is professionally qualified, or is sufficiently acquainted with the history of the case to give an opinion, are as well within the reasonable exercise of this power as the order of presentation of evidence, etc. It further must be held that, as each of these experts also testified from personal observation of the defendant, a direct question calling for their opinion *formed on* such an examination would have been competent. As the case stood, their opinions rested on the assumption of the truth of the uncontradicted testimony, so far as material, which each had heard, considered in the light of the knowledge of his intellectual condition previously obtained from actual contact. The number of witnesses does not alter the practical operation of the rule, if there was no *conflict* of evidence, or the facts so complicated that there may be danger of the jury being confused and misled. But if the evidence is of a complicated and contradictory character, and such that it would be likely to be understood differently by intelligent jurors, the question should call for the facts on which the opinion is founded. Evidence descriptive of the attitude and appearance of the defendant when under scrutiny by one of the experts was entirely competent, either as being in the nature of a conversation with him, or as furnishing a reason for the opinion of the witness. But an exception taken to the omission of any instruction that experts, when testifying as witnesses, must state the grounds or reasons for their opinions, was untenable. If the defendant desired their reasons, his counsel were not precluded from asking for them on cross-examination. There is no general rule of practice which makes it imperative on the party calling such a witness, that, after he has been duly qualified and given an opinion, his reasons therefor also must be stated, though it is frequently done.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

September 2.

1 *Cryoscopy. T. Tieken, Chicago.
2 *Study of the Gastric Contents in Urticaria. L. K. Hirshberg, Baltimore.
3 Bacterial Flora of the Intestinal Mucosa and Conjunctiva of the Normal Chicken. W. E. King, Ithaca, N. Y.
4 *Arteriosclerosis Affecting the Nervous System. B. C. Loveland, Syracuse, N. Y.
5 *Etiology and Diagnosis of Early Tubal Pregnancy. W. E. Ground, Superior, Wis.
6 *Some Gynecologic Superstitions. L. Waite, Chicago.

1. **Cryoscopy.**—Tieken reviews the literature on the subject, and gives a résumé of the work done and conclusions drawn by various writers.

2. **Gastric Contents in Urticaria.**—In eight cases of urticaria, Hirschberg noted the frequent coincidence of hyperacidity in this condition. Five of his eight cases showed a high total acidity, with much free hydrochloric acid.

4. **Arteriosclerosis Affecting the Nervous System.**—Loveland says that arteriosclerosis affecting the nervous system naturally would be divided into three or possibly four classes: cerebral, spinal, peripheral and possibly sympathetic. Cerebral arteriosclerosis may be divided into a major and a minor type. The major type passes rapidly to apoplexy and paralysis or death, and has few symptoms early in its course. The minor type comprises a complex of symptoms which are the direct expression of the vascular change, exclusive of such accidents as hemorrhage and its consequences. The symptoms include fatigue or exhaustion of the brain; the inability to take up new work, while familiar work can still be done; headache, usually frontal and persistent, increased by stooping and abdominal pressure; slight vertigo and loss of memory—in fact, the symptom-complex so frequently associated with neurasthenia. Arteriosclerosis of the spinal cord has the same major and minor types, the former marked by small hemorrhages, paralysis and rapid degeneration and myelitis; the latter by the slower degenerations of the cord such as the locomotor ataxia following syphilis. The effect of arteriosclerosis on the peripheral nerves is well illustrated by intermittent claudication, Reynaud's disease, acroparesthesia and quite a variety of sensory disturbances in the extremities such as persistent coldness, formication, itching or burning sensations, and possibly the neuritis so frequent in gouty diabetes. The effects on the sympathetic nerves are not so easily recognized, but when the arterial trouble can be determined elsewhere such symptoms as cardiac irregularity, some vague nervous sensations associated with digestion, persistent flushing of the skin sometimes associated with albuminuria, may be attributed to this cause. The treatment is the same so far as medicine and diet are concerned as in general arteriosclerosis; the two points which make for the best success are early diagnosis and persistent, continued care.

5. **Etiology and Diagnosis of Early Tubal Pregnancy.**—Ground has operated in 28 cases of tubal pregnancy. Of these, 21 patients were operated on after rupture and 7 before rupture had occurred. In all prerupture cases abdominal sections were performed. Of the complicated cases 16 were suprapubic

and 5 vaginal. All the patients recovered. All had demonstrable lesions sufficient to account for the arrest of the fecundated ovum in the tube. The results of gonorrheal infection and minor postpuerperal lesions were most frequently noted as etiologic factors.

6. Some Gynecologic Superstitions.—Waite states that gynecology has been encumbered with numerous dogmatic theories which have been stated and restated so many times that they have been finally accepted by the profession without question and have become veritable superstitions. She takes up the questions especially of backache and constipation as symptoms supposed to be caused by retrodisplacements of the uterus and shows by statistics that both of these conditions are present in a large percentage of antipositions and absent in a fair percentage of retropositions. In 1,000 cases taken from her clinic at the Mary Thompson Hospital 44 per cent. of the patients with antiposition gave a history of backache and 41 per cent. of the patients with retrodeviation stated definitely that they did not suffer with backache. In 500 cases 52 per cent. of the patients with antiposition gave a history of constipation, and of the cases of retroposition 34 per cent. of the patients reported normal bowel movements. The question of childbearing as a remedy in dysmenorrhea is also discussed. Of 300 patients the question, "Have you more or less pain since the birth of your children?" 45 per cent. reported more pain, 30 per cent. less and 25 per cent. no difference. Waite believes that the practical application of the statistics relating to the clinical significance of retroposition of the uterus bears directly on the enormous amount of unnecessary operating which is being done under the false impression that the symptoms of which the patient complains are due to the position of the uterus and the complications which are in reality responsible for the symptoms are overlooked.

Medical News, New York.

September 2.

7 Prognosis in Syphilis. R. W. Taylor, New York.
8 Prognosis of Syphilis: Relations to Marriage and Heredity. P. A. Morrow, New York.
9 Dermoid Cysts of the Mediastinum. (Continued.) R. S. Morris, Ann Arbor, Mich.
10 *Social Status of Tuberculous Persons. W. W. Pennell, Mt. Vernon, Ohio.
11 *Medical Treatment of Nephritis. A. R. Elliott, Chicago.
12 *Care of the Perineum, with Description of a New Method of Delivery of the Shoulder. H. K. Kerr, Hammond, N. Y.

10. Social Status of Tuberculous Persons.—Pennell directs attention to the danger of infection from a tuberculous person, the many sources of infection and what should be done in the matter. He says that the public should understand that tuberculosis is infectious to susceptible people; that it requires intimate and continued contact for others, but that daily contact with many different tuberculous persons may act as continued contact with one person; that houses in which tuberculous persons have lived or died are infected houses, therefore unfit to live in until thoroughly fumigated and cleansed. When persons are suspected of having tuberculosis and refuse to employ a physician, a health board should send a competent medical man to examine such invalids. On the filing of such examiner's report, if the persons prove to be tuberculous, the movements of the affected individuals should comply with the regulations made for the restriction of those maladies which are dangerous to others. Pennell urges a just, humane and adequate segregation of all cases of pulmonary tuberculosis.

11. Medical Treatment of Nephritis.—Elliott states that recent contributors to the therapy of Bright's disease, including von Noorden and his school, confine their attention too strictly to the kidneys, whereas the disease is a widespread nutritive disturbance involving the organism as a whole with the nephritis as but one manifestation. He urges the necessity of careful examination of the patient in all respects, and the correction of any other functional perversion which may be found to exist in order to eliminate sources of systemic toxemia. Individualism in the management of this disease is absolutely necessary. The medical treatment is discussed under the headings of: 1, Nephritis without dropsy; 2, nephritis with dropsy; 3, uremia. Cases of nephritis without dropsy are chiefly examples of chronic interstitial nephritis during the stage of cardiovascular compensation. The main indications in the management of this type of chronic nephritis are protection of the kidneys from irritation, especially the strain imposed by intercurrent acute toxemias, and secondly, the maintenance of cardiovascular compensation. The first of these two indications is fulfilled by regulation of the patients' diet and personal hygiene. The amount of water to be drunk and the hygiene of the bowels are of particular importance. The management of cardiovascular compensation becomes essential in the regulation of high blood pressure. Elliott warns against unwarrantable interference with medicinal measures. Diet, hygiene and free elimination of the bowels accomplish the purpose best. If these fail, and the patient suffers from excessive pulse tension, vasodilator drugs may be administered. The action of the various nitrites, aconite and iodids for the reduction of blood pressure is discussed. In nephritis without edema, digitalis and other cardiac stimulants are to be withheld and diuretics are not only unnecessary but harmful. When dropsy is renal in origin, diuretics have next to no influence. Prolonged rest in the recumbent position, restriction of fluid intake, hypochlorization, diaphoresis, colonic irrigation, subcutaneous puncture and paracentesis are to be employed. If the dropsy is of cardiac origin, cardiac tonics, rest and restriction of fluids are the measures indicated. The value of iron in Bright's disease is also discussed. In the prophylaxis of uremia the author lays great stress on the employment of purgatives and enteroclysis with alkaline solutions. The value of blood pressure observations in anticipating the advent of uremia is dwelt on, and the action of venesection and lumbar puncture in relieving the high tension of uremia is described. Elliott deprecates the attitude of pessimism toward the prognosis of Bright's disease which is held by so many of the profession. He calls attention to Nature's wonderful powers of adjustment in damaged organic states, nowhere so marvelously displayed as in organic kidney disease, showing that assistance only is needed, seldom interference. The two most important indications in the treatment of chronic nephritis are to protect the patient from intercurrent acute toxemias and to maintain the compensatory adjustment in the circulation.

12. New Method of Delivery of Shoulder.—With the patient on her left side, the head being delivered and rotation affected, Kerr places his left hand on the right side of the child's head and presses back firmly. This stretches the perineum from its circumference, laterally and posteriorly, toward the center and anteriorly. Muscular contraction is thereby almost entirely overcome. The perineum is temporarily paralyzed and is elastic like rubber and can hardly be made to tear. By carrying the left shoulder back into the perineum the right shoulder is lowered into the pubic arch. When a pain occurs the left shoulder can not descend, because it is held well back and high up in the perineum. The right shoulder, on the other hand, descends, and as it does so it describes part of a circle around the left shoulder held as a fixed point high up in the perineum, so that the course of the right shoulder is downward and slightly backward, bringing the prominence of the shoulder well back into the vulvovaginal outlet and the right arm below the shoulder into the pubic arch. One pain is usually enough to bring down the right shoulder and cause it to bulge well out of the vulva. This accomplished, the fingers of the left hand, with which backward pressure is being made, low down on the back of the neck or upper end of the spine, are closed and the physician presses up. This increases the space between the back of the child and the maternal soft parts on the left side below and also opens the right axilla. Through this opening in the axilla the forefinger of the right hand is passed and hooked around the arm, close to the shoulder, bringing it down behind the child's back out of the vulva and sweeping it over the pubic arch. Then, before relaxing the grip with the left hand, the right hand is placed on the left side of the child's head and, with the left supporting the perineum, by a downward, forward and slightly upward movement, delivery is effected. Thus, before there is the slightest strain on the anterior part of the perineum, the long diameter—from the tip of one shoulder to the tip of the other (bisacromial)—is exchanged for the shorter diameter—from the axilla to the tip of the opposite shoulder (axilla-acromial) as a presenting part, the difference again between laceration and practically no danger of laceration. This procedure is mainly applicable to uncomplicated cases, which are in the great majority. It can be employed in most forceps cases by removing the instruments.

Medical Record, New York.

September 2.

13 *Two Cases of Functional Strabismus. D. B. St. J. Roosa, New York.
14 *Food Factor in Uricemia. F. Hare, London.
15 *Tuberculosis Clinic at Gouverneur Hospital. S. S. Bradford and N. G. Seymour, New York.
16 *Cystoscopy and Ureteral Catheterization in Gynecology. H. D. Furniss, New York.
17 *Abuse of Bromids in Epilepsy. W. P. Spratling, Sonyea, N. Y.
18 *Convenient Points for Intramuscular Injections in the Treatment of Syphilis. V. C. Pedersen, New York.
19 Case of Acute Hemorrhagic Pancreatitis. C. M. Tinney, Charleston, Wash.
20 *Hospital Building in the Philippine Provinces. D. G. McCaskey, Buena Vista, P. I.

13. **Functional Strabismus.**—Roosa's first case did not yield to the treatment usually employed, but finally, after two and a half years, after all treatment except the use of the stereoscope and correcting glasses had been dropped, the intermittent strabismus ceased and has not returned. The other patient was cured by the use of glasses and exercises which involved exclusion of the good eye at intervals, and the use of the stereoscope. Now, at the end of eight years, the strabismus has disappeared, though correcting glasses are still worn.

14. **Food Factor in Uricemia.**—Hare analyzes the conditions, such as diet, exercise, pyrexia, neuroses, etc., which induce "pyremia" or uremic variations. He says that there seems to be little doubt that uric acid excretion depends directly on the introduction of uric-acid forming material, and inversely of the degree of pyremia. There will thus be at least a double column of variations in the excretion of uric acid. But since on a mixed diet, the introduction of uric acid material is for the most part approximately concurrent with the increase of "pyremia" due to meals, it follows that the resulting opposite variations in uric acid excretion will overlap and tend to obscure each other. The argument for the twofold causation of uricemia and uric acid excretion, seems, in his opinion, appropriately clinched by the following two pertinent observations: 1. The delayed excretion of uric acid which in the gouty follows the ingestion of uric-acid forming material. 2. The uniformity of uric acid excretion during starvation.

15. **Tuberculosis Clinic at Gouverneur Hospital.**—Bradford and Seymour state that 338 patients have applied for treatment at the hospital from October, 1903, to June, 1905. Two hundred of these were men, and almost one-half of the total number were Russians. Of the 338 cases 85 patients are still under observation, 120 have disappeared, 52 have gone to hospitals, to the country, or to their homes in Europe, 14 have been referred to other clinics as non-tuberculous, and 9 have died. Fifty-one patients have been discharged for insubordination. Seven patients have been discharged as "apparently cured," though they are requested still to report occasionally for observation. Such cases are those in which all constitutional symptoms and expectoration with bacilli have been absent for a period of three months, and the physical signs are those of a healed lesion. The authors believe that the clinic has accomplished four definite and excellent results: 1. It has withdrawn the tuberculous patients into a class by themselves, thus relieving the overcrowded medical clinic and providing some protection to non-tuberculous patients. 2. It has provided a place for the systematic treatment of ambulant cases of the disease in a district of the city thickly populated and extensively exposed to the contagion. 3. It reaches patients heretofore untreated, or treated irregularly and unsystematically. 4. The patients so treated have become a source of education in their homes rather than a menace to their associates.

16. **Cystoscopy and Urethral Catheterization in Gynecology.**—Furniss discusses the technic of cystoscopy, meatoscopy of the ureteral orifices, and ureteral catheterization. He gives the preference to an instrument of the water dilating variety, direct view with catheterizing attachment, as with this all of the bladder can be examined except the anterior wall, which is seldom affected, and catheterization of the ureters with a direct view instrument is far easier than with one of the prism type. The subject of ureteral meatoscopy is given much importance, and the use of the ureteral catheter in hysterectomies, stricture of the ureter, etc., is described. Furniss recommends lavage of the renal pelvis for pyelitis, but believes that the cases of Bright's disease reported benefited by this means were really ones of pyelitis with a few casts in the urine, rather than cases of true nephritis.

17. **Abuse of Bromids in Epilepsy.**—Spratling says that bromids have a limited range of usefulness in their power of suppressing epileptic convulsions, but he has never given the bromid of potassium to an epileptic, and says that the cases must be carefully selected for the use of the other salts. At the Craig Colony the average dose of the drug is 15 grains a day, 5 grains at a time. Spratling personally analyzed twenty-seven patent nostrums for epilepsy and found that the basis of all, without exception, was bromid of potassium. If recoveries occur under the use of the drug, it is in spite of it and not on account of it. When used the bromids must be prescribed with the greatest caution, and it is rarely necessary to push them to the point of producing acne. Their disadvantages are many, and it is preferable to use other harmless depressants in their stead, and to treat the individual instead of one of the symptoms of his disease.

18. **Intramuscular Injections in Syphilis.**—Pedersen describes and illustrates a plan of subdividing the two gluteal regions into four quadrants and making three injections in each of these in rotation in such a manner that the same spot is made the site of operation only once in thirteen weeks. He also describes the technic of injection.

21. **Stokes-Adams Syndrome.**—Foley reports two cases and gives a short résumé of the literatrue.

22. **Relationship of Ulcer and Cancer of the Stomach.**—Graham says that clinical experience shows that the great majority of ulcers of the stomach are located at the pyloric end. The immediate pylorus comes first, the lesser curvature second. A small percentage is found elsewhere, few at the cardia. The great per cent. of cancers of the stomach is found at the pylorus and lesser curvature (pyloric end), that is, the same locations find the greatest number of each. Quite a per cent. (50 to 60) of patients suffering from carcinoma gives three or more years of a precancerous history. A growing per cent. of cancer cases are found with short histories and ulcer demonstrated as the earlier lesion. A certain per cent., if small, of short ulcer histories leading to acute pyloric obstruction where the ulcer must have been present for quite a period, and latent. Ulcers may be present for an indefinite period and no symptoms follow until obstruction, perforation and hemorrhage appear, if the acidity is low or absent and the ulcer locates itself along the lesser curvature or near the pylorus. Cancers may develop under the same gastric conditions and only manifest themselves when obstruction or systemic poisoning makes itself felt.

41 *New Instrument: To Shorten the Subjective Branch of Refraction and to Make it More Accurate. J. N. Rhoads, Philadelphia.

38. **Origin of Pain in Photophobia.**—Fridenberg distinguishes two classes of photophobia which differ in cause and mechanism, although both may be accompanied by similar external and superficial manifestations. 1. Specific, idiopathic, primary, retinal photophobia, representing a reflex from the optic nerve to the sensory branches of the trigeminus or ciliary nerve, or to the motor nerves of the eye and lids, and due to hyperesthesia of the nerve filaments engaged in light perception, or to excessive stimulation of normal structures. The discomfort in these cases is caused by intense "specific" stimulation of the retina; actual pain by iris cramp. This form is that observed in normal eyes suddenly exposed to glaring light, as in retinal asthenopia, neurasthenia, hysteria and perhaps in snowblindness. 2. Secondary, symptomatic, superficial, corneal photophobia, due to hyperesthesia of the sensory nerve terminals in the skin of the lids, cornea, conjunctiva, and ciliary body, as well is in the mucous membrane of the nose, in the maxillary antrum, teeth, and representing the reflex from the sensory fibers of the trigeminal nerve, and other nerves, to the motor branches of the facial. In this class of photophobia we have to deal with corneal or ciliary pain, absolutely independent of any process in the iris or retina. The most frequent causes of such pain are the irritation of the superficial nerve endings in abrasion or foreign body in the cornea, corneal ulcer, sympathetic iritis, cyclitis, ciliary wounds, and so forth. Of this form, which Fridenberg designates as pseudo-photophobia, or the blepharospastic syndrome, phlyctenular keratitis is a characteristic paradigm, and tonic blepharospasm the clinical expression.

41. **New Lens Holder.**—Rhoads has devised a lens holder which shortens the subjective branch of refraction and makes it more accurate. This instrument is six and one-half inches long, and contains a plus and minus lens of the same relative strength, that is, a plus 0.50 Sp., and a minus 0.50 Sp., or minus and plus quarters. The long straight shank has the minus lens attached to it and the short shank carries the plus lens. The short shank is movable and is held in place by a spring, but when its upper short end is pressed on it rises up parallel and directly over the long shank, and consequently the lenses neutralize each other, thus making a third glass. He also uses a pair of cylinders fastened to the same kind of shanks, which neutralize themselves in the same manner. The axes of the cylinders are placed parallel with and straight out from the shanks. The lens rings are one inch and a quarter in diameter. This instrument is just a little less important than Jackson's cross cylinder. It shortens the time consumed in refraction exceedingly, and renders the result far more accurate. After a patient has been shadow tested it rarely takes over five minutes with each eye to finish the refraction by this method. Owing to the short time it takes with this instrument and system, nervous and even illiterate women answer promptly and correctly, and thus are not tired out and sent home to their beds for a couple of days, as is quite often the result by the generally used method.

43 *Location of Extragenital Chancres. D. W. Montgomery, San Francisco.
44 *Case of Chronic Pyogenic Onychitis Cured by the X-Ray. G. E. Pfahler, Philadelphia.

43. **Location of Extragenital Chancres.**—Of 67 cases of extragenital chancre Montgomery noted the location of the lesion in 58 as follows: Lips, 25; tongue, 3; corner of mouth, 4; abdomen, 5; anus, 3; fingers, 7; forearm, 2; and one each on gums, tonsil, cheek, eye, neck, breast, nates, wrist and back of hand. Twenty of the lip chancres, or nearly 68 per cent., occurred in women. In 17 of these cases the lower lip was the one affected.

44. **X-Ray in Chronic Pyogenic Onychitis.**—The case cited by Pfahler resisted all forms of internal and local treatment and yielded to the *x*-ray in three months. *X*-ray treatment was given three times a week, with the tube six inches distant, a two and one-half inch vacuum and five minutes' exposure, using about 1 mp. through the tube. Improvement was noted after two weeks. Twenty-five treatments in all were given.

46 *Conservation of the Parietal Motor Nerves in Abdominal Section. V. P. Blair, St. Louis.

46. **Conservation of Nerves in Abdominal Section.**—Attention is directed by Blair to the necessity of conserving the motor nerves supplying the abdominal region when incising the parietes. He attempts to show how these nerves are to be avoided and to give the lines on which incisions may be made which will likely pass between the nerve trunks. He says of the various abdominal incisions that the least harmful is that made in the median line, either straight through or continued through the posterior wall of the sheath after the rectus has been drawn outward. It is only when these incisions are inadequate that we have to consider the nerves. Quite as harmless, if we avoid the nerve trunks, for it cuts no muscles is that made in the linia semilunaris. Some nerve fibers will be divided wherever we cut into muscle by any other method than proper splitting, but we can, in most cases, avoid the trunks. In the subcostal incision for approaching the gall bladder, which is four inches long parallel to and from one and one-half to two inches below the right costal border, the tenth and eleventh nerve trunks will be severed if the wall is cut straight through. The fibers of the internal oblique run parallel to the cut, so that it can be split, and in this way the nerves may be found and drawn aside. This might not be practical in the very stout. Even here part of the supply of the external oblique will be cut off, as it comes from the lateral branches. He advises approaching all obscure epigastric cases through an exploratory incision in the median line, and then, if a complicated gallstone operation requires more room, a cut can be made from the umbilicus toward the cartilage of the eleventh rib and a flap turned up containing the eighth, ninth and tenth nerves, and more room be gained than by any other incision. If it proves to be a gastric case demanding freer access, a supplementary transverse incision may be made between the eighth and ninth, or ninth and tenth nerves, preferably the former, which will not cut nerve trunks. Then, if the wound has been kept clean and well sutured, there need be no fear of hernia. In the splitting operation no nerves will be cut if Kocher's admonition is heeded, which is to use hooks and to tear the muscles apart. Practically the crooked thumbs are sufficient. Kocher's incision for appendicitis would most likely be below the twelfth nerve, provided the incision does not extend backward beyond the anterior iliac spine. The cut for suppurating cases, made one finger's breadth above the ligament, would in most cases go above the hypogastric

nerve. An extensive lumbo-lateral abdominal incision that cuts no nerves may be made as follows: A flap of any size may be raised by cutting from the tip of the last rib to the linea alba between the eleventh and twelfth nerves and then extending the incision in the median line. All of these may be modified so as to divide the rectus transversely. All incisions should be made to allow some variation, and it is only in through-and-through cuts that the variation can cause trouble.

50. **Unusual Case of Edema Glottis.**—The point of interest in Mayer's case lies in the fact that the edema of the glottis was engrafted on a hereditary syphilis of the epiglottis, which latter never produced any noticeable symptoms relative to the throat, except a constant cough of twenty-eight years' duration. The absence of any initial lesion, as also of any evidence of the disease elsewhere, pointed strongly to the hereditary nature of the affection. The case also illustrates the advantage of prompt, free and deep incisions into the edematous tissue, thus avoiding the graver operation of tracheotomy, and emphasizes the value of adrenalin in the subsequent treatment of these conditions.

59. **Negative Value of Kernig's Sign.**—Willson examined 120 cases of all kinds for the purpose of determining the clinical value of Kernig's sign. As a result of his study he concludes that Kernig's sign is by no means a positive indication of either meningeal or brain or cord involvement, but that when present in association with other signs of meningitis it may be looked on as confirmatory to a high degree. Undoubtedly, in the majority of cases, it persists far into the convalescence, and is usually one of the last signs to disappear. In certain cases it probably remains as a permanent indication of a former undetermined lesion.

66. **Typhoid Appendicitis.**—A case of typhoid appendicitis without other intestinal lesions is reported by Stokes and Amick. Thirteen years previously the patient had a very severe attack of typhoid. His last illness began with a severe pain in the entire abdomen, which later became localized in the right iliac region. This was followed by nausea, vomiting and slight diarrhea. An appendicectomy was performed, and the patient made a complete and uneventful recovery. The appendix was about three times the normal size and about midway between the tip and the intestinal attachment. The wall was thin and gangrenous and about to rupture from distension. The mucous membrane was covered in places with a dirty, gray, fibrinous membrane, and at its base there was an irregular ulcer. The lumen contained three soft, putty-like, light yellow concretions. The *Bacillus pyocyaneus* and *Bacillus typhosus* were found in stained sections. In some portions of the appendix the pathologic change corresponded to that seen in acute diffuse appendicitis, while in other portions where there was no surface ulceration the changes were more characteristic of typhoid, and were probably the reaction to the presence of the typhoid bacillus.

68. **Cesarean Section.**—Voorhees reports seven Cesarean sections, and reviews the history of this operation as found in the literature. He concludes that Cesarean section is a dangerous operation only when infection is present; that there are too many fetal deaths from the other major operations; that in view of the low maternal mortality the field for Cesarean section should be broadened; that in contracted pelvis of a moderate degree (in the border line cases), a late induction of labor is justifiable; that when possible, difficult versions, prolonged forceps operations, and high forceps operations, performed in early labor, should be avoided. That craniectomy on a living baby is an operation only of necessity and emergency; that symphyseotomy is an operation of the past.

73. Id.—June 10, 1905, page 1878.

74. Id.—June 17, 1905, page 1955.

75. **Removing Appendix When Abdomen Is Opened for Other Lesions.**—Baker cites cases to show that the presence of adhesions of, or fetal concretions within the appendix are not the only evidence of appendicitis which should influence the surgeon for its removal. The appearance of the normal appendix at the time of the operation has proved to be unreliable, as in three-fifths of the cases reported the patients were suffering from chronic appendicitis. The advantages to be derived as a prophylactic measure from the removal of the appendix, even in cases which prove normal, far outweigh the slight additional risk incurred by the operation. The great frequency with which appendicular troubles present themselves warrant not only the removal of the appendix, when it is easily accessible, when performing abdominal section for other lesions, but also the careful searching for and removal of it even though it may appear normal from its gross appearance.

77 *Syringe Versus the Irrigator in Gonorrhea. F. C. Valentine and T. M. Townsend, New York.
78 *Some Untoward Results of Perineal Prostatectomy. G. S. Whiteside, Portland, Ore.

77. **Syringe versus Irrigator.**—Concisely stated, the position held by Valentine and Townsend with reference to the value of the irrigation treatment of gonorrhea is as follows: Even the mildest manifestation of gonorrhea spells a dangerous disease to the patient, to his wife, to his children and to the community. No honest, conscientious advocate of the irrigation treatment of gonorrhea ever claimed that a patient was cured before all the tests which present science demands have shown the permanent absence of gonococci. The irrigation treatment, like any other treatment, is positively dangerous, unless employed with caution, tact and gentleness. The immense numbers of gonorrheas successfully treated by irrigations, owe their recovery to the operator's gentleness and judgment. The technic of irrigations is not so difficult to acquire, but their successful employment requires the same scrupulous attention to details that is demanded by every other remedial measure in any other disease. The choice of

drugs used in irrigating solutions is not limited to potassium permanganate, silver nitrate or mercuric bichlorid, but is governed by the needs of each case. The guides for the selection of drugs and the strength of the solutions employed are, the condition of the discharge, the microscopic and cultural results, the character of the urine, and such involvements of the major and minor adnexa as may exist. Chronic gonorrhea is always dependent on infiltration of the urethral mucosa, involvement of the urethral crypts, glands and follicles, or invasion of Cowper's glands, the prostate or seminal vesicles, or all these; therefore, treatment of these extensions of the disease is necessary in conjunction with irrigations. When a patient with acute anterior gonorrhea comes under treatment before the adnexa are involved, he will escape complications, if irrigations are cautiously, skillfully, gently and judiciously employed. No other form of treatment will relieve pain and reduce discharge as quickly as do properly administered irrigations.

78. **Perineal Prostatectomy.**—A critical study of 238 cases, collected from many sources, leads Whiteside to say that perineal prostatectomy is considered by the majority of surgeons as the best operation in most cases. Immediate deaths result from sepsis, shock, cardiac disease, pneumonia and uremia. Remote deaths from cancer cachexia, pyonephritis embolism, and the result of secondary operations to overcome defects left by the first. Absolutely good results occur in about 30 per cent. of all the patients operated on. Sequelæ are numerous and troublesome. They include rectal fistula, urinary sinus abscess, stricture at the bladder neck, incontinence, frequency of micturition, residual urine, epididymitis, sexual impotence, cystitis, vesical calculus and urinary tuberculosis. Mistakes in diagnosis are not uncommon even in the experience of the most skillful. Carcinoma, sarcoma and syphilis have all proved stumbling blocks.

81. **Estimating Functionating Capacity of Kidney.**—Kalkes considers chromocystoscopy the safest, simplest and most practical means of ascertaining the presence of the kidney. The existence of the second functionating kidney should always be assured before doing any cutting operation on the kidney, especially a nephrectomy. For practical purposes the function of the kidney is best determined by chromocystoscopy, by cryoscopy and by the phloridzin test. Of less importance for the surgeon, but of interest for laboratory investigations, are the determinations of the toxicity and electric conductivity of the urine. The most reliable method of obtaining the separate urine from each kidney is by ureteral catheterization, but this procedure requires special skill.

89 *Simple Method of Hystero-myomectomy by the Aid of a Dagger Clamp. H. M. Hepperlen, Beatrice, Neb.

89. **Use of Dagger Clamp in Hystero-myomectomy.**—The method described by Hepperlen is somewhat similar to Kelley's method. The patient is placed in the horizontal position. The abdominal incision does not exceed three inches, except when the tumor is a very large one. After the tumor is delivered a hot, sterile towel is placed snugly in the opening, having the edges come well around the neck of the tumor. The bladder is freed, if it is attached, and if the neck of the tumor can be well drawn up, Hepperlen inserts the dagger of his clamp through the center of the neck, from right to left, leaving as much of the cervix as is necessary. He then applies the clamp over the dagger, which can be drawn up to any size desired, and clamps over the neck of the growth. The ovarian arteries are then ligated on either side close down to the clamp and the tumor removed by making a "V"-shaped cut from either side of the neck down to the dagger. The uterine arteries and veins are picked up and tied twice with Tait's fine table-twist silk. Both sides of the clamp are then opened, one at a time, to see that all hemorrhage is controlled. The stump is then closed over with catgut sutures, from four to six in number, leaving them long so that the stump can be held up by them after the dagger is removed for the purpose of inspecting the large vessels. With the fine catgut suture the whole field is closed over from left to right by stitching the peritoneum over the ovarian vessels and stump, as recommended by Kelley. In the beginning of the operation, should there be adhesions which bind down the tubes and ovaries in the broad ligaments, the ovarian arteries are ligated and cut down on each side of the broad ligaments. This makes it very easy to raise the neck of the tumor up far enough to insert the dagger as low as desired. Hepperlen says that the operation is bloodless; that it can be done in less than half the time required by any intraperitoneal method; that there is less exposure of the internal viscera and less shock, with a lower mortality, than from any other method.

9. Congenital Hypertrophic Stenosis of Pylorus Treated Without Operation.—About *three* weeks after birth, the Harpers' patient began to manifest the symptoms of pyloric stenosis, and these were confirmed by careful physical examination. The question of operative interference was frequently discussed *during the earlier stages of the child's condition,* but was abandoned owing to the apparently hopeless condition. Abdominal massage with cod-liver oil was resorted to in despair, and from the progress of the case it was evident that a certain amount of oil was absorbed *through the skin,* and to this fact the authors attribute a certain proportion of the success of the treatment. The infant also received injec*tions of normal* saline solution, about half a pint, twice daily, and small quantities of peptonized milk and water every two hours for about four weeks, and with but few additions for three months. In massaging the abdomen, particular attention was paid to massage of the stomach wall toward the pylorus. The authors appear to consider the massage and the saline injections the essentials of the treatment.

10. Subdiaphragmatic Transperitoneal Massage of Heart.—Gray's *patient was apparently dead from a cancerous obstruction* of the larynx. There was no pulse at the wrist, no cardiac impulse, no cardiac sounds, and all the evidences of death were present. The abdomen was opened in the middle line immediately under the xiphoid cartilage, and through this opening the heart was massaged about four minutes, the rate of compression being from 70 to 90 per minute. After ten minutes of massage, the heart began to beat and the patient took a rather deep spontaneous breath. Slight hemorrhage occurred from the abdominal wound. The patient died about three hours afterward, having never regained consciousness.

12. Mixed-Cell Leukemia.—A case of this *kind* is reported by Browning occurring in a man, aged 57. He summarizes his paper as follows: 1. Myeloid leukemia is due to a hyperplasia *of myeloid tissue;* but the unknown causative agent is irregular in its action, so that any of the various granular types may predominate or a mixed-cell blood picture *may* result from the reversion of many of the cells to the condition of the non-granular undifferentiated leucoblast or from the hyperplasia of such non-granular cells normally present in the marrow in small numbers. These undifferentiated leucoblasts may assume their embryonic activity and secrete granules. 2. In leukemias a mixed-cell blood picture may be due to: (a) a reversion of myeloid cells to the embryonic non-granular type; and (b) a reaction or mechanical disturbance of *myeloid tissue owing* to lymphoid hyperplasia with as a result the passage of myelocytes into the circulation. 3. It is to be understood that it is left quite an open *question as to* whether or not myeloid and lymphoid tissue may be concomitantly affected *in a* way *similar* to what occurs in myeloid and lymphoid leukemias, respectively. *If* such occurred then we should have a mixed leukemia, in the strict sense.

18. Addison's Disease.—The special points of interest in the two cases reported by Gullan are the severity and rapid progress of the disease in one of the cases, though the lesion was that of chronic *tuberculosis* of the suprarenal bodies, plus secondary inflammation of the neighboring *sympathetic,* and the little benefit derived from the administration of suprarenal extract, so that the patient easily stood the strain of pregnancy and parturition, are the points of interest. The suprarenal extract was given in doses of up to 20 grains three times daily, beginning with a five-grain dose.

25 Puerperal Convulsions. A. M. Dallas.

21. Typhoid in India.—Although for *many* years it was a disputed point whether or not the natives of India could *ever* contract typhoid, the results of recent observations on this subject, according to Row, may be taken to leave no doubt that these natives not only do get the disease, going through the usual clinical course, but also that the nature of the disease can be verified both bacteriologically and, when occasion arises, postmortem. Row has confirmed this belief by a careful study of twenty-three cases.

23. **Flies and Plague.**—The experiments and investigations made by Windsor with a view of obtaining evidence for or against the conveyance of plague infection by flies showed that flies which have had access to material containing plague bacilli (i. e., the plague blood in the watch glass) can carry infection and inoculate a wound. Hence, the sputum from a case of pneumonic plague and the juices of a fresh plague body (as in a postmortem room) may be a grave source of danger Such flies do not appear to convey infection by means of food on which they settle. Flies which have had access to a plague body, but not to the fresh juices or blood, do not appear to be a source of danger. It is almost certain that the juices arising from decomposition do not contain living plague bacilli. In the experiments the absence of fleas from all the rats was insured.

31 Sudden Case of Goiter. W. Macansh.

28. **Liquid Air in Surgery and Skin Diseases.**—Liquid air, if applied to the skin lightly and cautiously repeated for a few minutes, Beckett says, will produce a refrigerating effect of any degree of intensity desired, with a resulting complete local anesthesia under the influence of which small surgical operations can be done. If applied too freely and for too long a time, frost-bite effects are produced, even to causing ulceration of the skin. The application is not painful unless the parts are tender and sensitive. Beckett has made use of liquid air in cases of a superficial and more or less malignant nature that have existed and have been incurable for a length of time, such as lupus, rodent ulcer and small epitheliomas. Compared with the *x*-rays, the effect of liquid air is instantaneous; it acts superficially and its use is very simple. All the apparatus required, besides the liquid air, is a suitable glass rod with a small piece of cotton wool wound around the tip of it, the size and shape depending on the degree of intensity required to be attained. When the surface is raw or ulcerated, it is advisable to cut and to place over it a small piece of gauze; otherwise the cotton wool will be quickly frozen to the surface.

29. **Treatment of Arteriosclerosis.**—The systematic employment of hot baths is vaunted by Hirschfeld as a satisfactory treatment of arteriosclerosis. The effect of the hot bath on the patient suffering from arteriosclerosis is fourfold: 1. It alters the distribution of blood pressure by unloading the internal organs and by increasing the vascularization of the skin; hence, it affords prompt relief in many of the cases of pain associated with internal gout, that frequent source of arteriosclerosis. 2. It increases combustion. 3. It increases the elimination of waste products. 4. By opening the channels of the skin, it reduces the pressure of the blood by bleeding the patient into the skin. In every instance, it is necessary to ascertain exactly the reaction of the individual. One may safely begin with a temperature of 102 degrees if the patient is not above 55 or 60; in women it is safer to begin at 100 degrees. The time of immersion should not be less than ten minutes, although Hirschfeld rarely had to exceed that time. The determining factor in the management of the patient is the condition of the left heart, the quality and loudness of the first and second aortic sounds. Without a vigorous left heart the hot bath must be used with caution. Hirschfeld warns against the indiscriminate use of the hot bath when there is not a good systematic pressure and a vigorous systolic output to start with. While these two conditions obtain in arteriosclerosis, favorable results will follow the treatment indicated.

34. **Resection of Nerves in Painful Gangrene.**—Bardesco has found it necessary to relieve the pain of gangrene of the leg before he could proceed to amputation. Stretching the nerve brought transient relief, but epidural injections of cocain were entirely useless. He finally resected the internal and external popliteal nerves for a distance of about 5 cm. The pain was arrested at once and the general health improved, the edema of foot and leg subsided and the gangrene became demarcated. The portion finally requiring amputation was much smaller than was at first supposed necessary, and the patient was spared unnecessary crippling. Recovery was rapid and complete, and no sensory or trophic symptoms have developed to date. He proposes in future merely to sever the nerve and to suture the wound. This would relieve the pain while the nerve would become regenerated later, allowing the gangrene time for elimination. These operations on the nerves enable the secondary amputation to be done under much more favorable conditions.

36. **Thermic Inversion and Monothermia.**—Gilbert applies the first of these terms to a condition in which the temperature reaches its maximum in the morning. He has coined the second term to express the condition in which the temperature remains the same morning and evening. Both are probably due to the influence of some digestive or biliary toxic infection, and are liable to be observed in almost any affection due to autoinfection.

37. **Vacuum Cleaning Applied to Operative Wounds.**—Laurens gives an illustration of his little vacuum aspirator, attached to a faucet. It works on the principle of the vacuum cleaning apparatus, sucking all the fluids and loose particles out of the wound. He has found that it reduces the length of otorhino-laryngeal operations, prevents aspiration of secretions and keeps the wound cleaner than any other measures. It does not siphon out blood, as the mouthpiece is placed over the wound only when there are secretions, blood and scraps to be aspirated, and is not kept there all the time. Of course, tamponing is necessary in some cases, but in the majority this aspiration technic is sufficient and renders the compress superfluous. The operator has always a clean field before him.

38. **Diuresis from Drinking.**—Labbé's tracings show the prompt diuresis that follows ingestion of liquids fasting. When taken with food they are not evacuated so promptly by the stomach. He suggests the term "oligoposy" to express the disturbances that result from not drinking enough fluids. It entails oliguria, irritates the kidneys, produces albuminuria and leads to gout. A large glass of any warm infusion, morning and evening, washes out the organism effectually.

40. **Burette Vials.**—The outer part of the large stopper of the vial is like a graduated inverted test tube. The male portion of the stopper is shaped like a syringe piston and its prolongation extends nearly to the floor of the vial for a delivery tube. Inside it is a loose glass plug to act as a valve. When the graduated part is fitted over the inner part of the stopper the fluid in the vial rises into the hollow inner part whenever the female part of the stopper is slightly raised. The communication between the aspirated fluid and the body of the vial is interrupted by the glass plug which serves as a valve to close the lumen of the inner part of the stopper. The fluid that has been thus aspirated into the graduated part of the stopper can then be used at will for hypodermic injection or otherwise. The tip of the outer stopper is finished so that a Pravaz needle can be screwed on it, or it is bent like a retort with a cup on the end to hold the fluid. An illustrated description of the vial is also given in the *Bulletin de l' Acad. de Méd.*, No. 30.

42. **Pathogenesis of Malaria.**—Le Ray has had long experience in the tropics and he has become convinced that the frequency, the persistence and the intensity of epidemics caused by infectious germs are determined: 1, By the degree of concentration of some miasma in the atmosphere, that is, the degree of toxicity of the gases emanating from the decomposition of some special organic matter; 2, by the evolution of the meteorologic phenomena before and during the epidemic; 3, by the degree of the physiologic fatigue experienced by the people in general and by individuals in particular. Pathogenic germs may remain a long time in a state of latent microbism, but this state is extremely unstable, depending on the relations between the nervous energy and the sum of the forces striving to break it down.

44. **Foreign Bodies in Esophagus.**—Moure preaches that radiography should be applied as the first measure in case of a foreign body in the esophagus. Blind attempts to extract the body and external esophagotomy should be very rarely attempted nowadays.

45. **Diabetes of Infectious Origin.**—Labbé's patient was a man of 45, obese, previously healthy, who had a febrile sore throat. Immediately after recovery symptoms of diabetes developed, disturbances in vision, polyuria, emaciation and elimination of 415 gm. of sugar a day. He was placed on a diabetic diet with two glasses of Vichy before meals. All symptoms of the diabetes had vanished by the end of a month, and the patient has been in perfect health during the two years since. Another patient was a woman of 67, obese at one time, but not for several years. After an acute febrile nasopharyngeal infection she likewise developed symptoms of diabetes, which also subsided after a few weeks of dieting and Vichy water. Labbé reviews the literature on the subject and remarks that the classification of diabetes as pancreatic, nervous, hepatic, etc., is illogical. The functioning of the sugar-regulating apparatus is disturbed, not any special organ in the group forming this apparatus.

52 (No. 32.) New *Prussian Law* on Communicable Diseases.—La nouvelle loi prussienne sur les maladies transmissibles. De Maurans. See foreign news columns.

50. **Treatment of Phlebitis.**—Vaquez outlines the treatment suitable for obliterating phlebitis of the large veins, for subacute venous septicemia and for recurring phlebitis. Immobilization in the former should be absolute. He does not use a cast, but holds the leg immovable by strips across it at the knee and above and below, the strips pinned firmly to the mattress. Another strip holds the foot immovable at a right angle to the leg. A strip across the lower part of the trunk is likewise pinned to the mattress or tied to the side bars of the bed. This technic allows supervision of the various parts of the limb without raising it, as would be necessary with a cast. Sedative applications at first are followed by fomentations with a natural saline water for three or four hours, the part powdered with talcum, chalk, magnesia and resorcin powder in the interim. When the temperature has been normal for twenty days, and the veins are indolent to palpation and the edema is retrogressing, then partial passive mobilization may be commenced, limited to ankle and toes. From the twenty-seventh to the thirty-fifth day the muscles may be massaged, and at this time the knee and the trunk can be released. By the fortieth day the patient can be allowed to take a few steps. An elastic stocking should not be worn at first, but merely a light bandage wound from the foot to the thigh before the patient is allowed to get up. This promotes the establishment of collateral circulation. A crutch should not be allowed, as this favors vicious attitudes. Subacute venous septicemia or multiple, relapsing phlebitis, requires different treatment, measures to combat varicose congestion and to prevent the entrance of germs into the enlarged veins. The slightest phlebitis of this nature demands rest in bed with immobilization for twenty days, followed by passive movements of the joints; the rest of the limb does not require mobilization or massage, and these measures arouse the phlebitis again. An elastic stocking is needed when the patient gets up. Surgical intervention should be reserved for protracted phlebitis with successive emboli from disintegration of the clot and danger of septicemia. It is also indicated in case of circumscribed, infected varicose ulcers. Each reawakening of the subacute venous phlebitis should be treated like a new focus, and mobilization should not be commenced until twenty days after the temperature has returned to normal. Local treatment should be the same as previously mentioned. The fomentations are especially effectual in aiding resolution in these cases, as the veins and perivenous surrounding tissue are accessible. In recurring phlebitis in gouty subjects, immobilization is still the rule, for mobilization, massage, etc., do more harm than good. Postphlebitic accidents are generally the result of absurdly long immobilization, from three to twelve months. The pain and edema are best treated by mild hydrotherapy, effleurage and electricity. Massage under hot running water acts on the trophic trouble and on the muscular atrophy common in postphlebitic edema. He asserts that this delicate but energetic treatment which he recommends for the various forms of phlebitis, effects cures without causing a train of sequelæ.

51. **Sudden Death in Pleurisy.**—In menacing death from asphyxia in pleurisy, preventive treatment should include punctures, lying on the affected side and refraining from any exertion and from drugs that may depress the respiratory functions, such as morphin. When the impending fatal termination is due to reflex inhibition, preventive treatment should aim to avoid sudden movements, exertion and constipation. Morphin should be given in case of violent cough or pains. Curative measures should comprise massage and electricity to the heart, artificial respiration, traction of the tongue and stimulation of the skin. The asphyxia is generally preceded by attacks of dyspnea and inability to lie on the sound side, cyanosis and signs of heart weakness.

53. **Operative Treatment of Puerperal Pyemia.**—Bumm relates the histories of 5 patients with puerperal pyemia treated by ligation of the ovarian and hypogastric veins, with 3 recoveries. One was a case of acute pyemia after abortion, the others were chronic cases. His experience teaches that it is not necessary to attempt the extirpation of the uterus in case of puerperal pyemia, but merely to ligate and to resect the affected ovarian veins and to be content with simple ligature of the hypogastric veins. Applied in time, these measures are almost certain to cure. As the circulation through the parts is arrested, the suppurative thrombotic masses are no longer swept into the general circulation and the chills cease. The pus will be gradually absorbed in the tied-off portions of the veins or a local abscess may form, requiring evacuation. Abortive chills and moderate temperature, such as follow operations for sinus thrombosis, are liable to occur when the abscess is opened, but cause very little disturbance. In the acute case, the blood was being overwhelmed with infectious matters and the number of polynuclears and eosinophiles was constantly declining, but as soon as the veins were ligated, these cells rapidly increased and soon regained their normal proportions.

54. **Treatment of Vaginismus.**—Budin has cured a number of patients by stretching the entrance to the vagina under local anesthesia with vaselin containing 1.2 parts cocain to 30 parts vaselin. He accomplishes this by gradual dilatation with the vaselined fingers and the introduction of Hegar tents.

55. **Tearing Open of Old Cicatrix from Cesarean Section in Later Pregnancy.**—Werth has had an experience of this kind, and analyzes 11 similar cases in the literature. Among the points learned is the importance of preventing vigorous contractions of the uterus after the Cesarean wound has been sutured. The contractions should be reduced to the minimum, as they interfere seriously with the consolidation of the wound. The uterus should not be tamponed, on this account, unless absolutely necessary, and only to the smallest possible extent. The wound should be sutured to ensure perfect adaptation and rest and to promote healing. The diagnosis of rupture of the uterus was generally easy on account of the indications of severe internal hemorrhage, but in a few instances the general health did not seem to be much impaired, as the loss of blood was comparatively small, owing to the location of the placenta just below the old scar. This allowed the fetus and after-birth to pass at once through the rupture, and the hemorrhage was arrested by the retraction of the emptied uterus.

56. **Myoma and the Menopause.**—Winter's statistics show that the menopause did not occur until after 55 in a third of his 718 cases of myoma. Of his 437 patients under 45, only 9 were in the menopause, only 15 in 170 were between 45 and 50, while the menopause had just commenced in 37 out of 111 over the age of 50. His experience further indicates that patients with myoma are liable to serious symptoms at any time until after the menopause is fully established. Fully 17 per cent. of his patients had to submit to an operation for myoma after the age when the menopause usually commences in normal women. In 19 cases, the myoma caused disturbances necessitating an operation some time after the menopause had been fully established, but in the majority of cases the latter arrests the growth of the neoplasm, and abolishes all disturbances from it, as the myoma shares in the senile involution of the uterus. The symptoms observed from the myoma in the menopause may be due to the expulsion of a subserous myoma or to an increased tendency to sarcomatous degeneration or to hemorrhages. Myomata sometimes continue to grow after the menopause. In his patients, operations undertaken for myoma during the menopause represent 5 per cent. of a total of 392.

61. **The Spirochete and Syphilis.**—Babes and Panea found the *Spirochæte pallida* in one case of congenital syphilis almost immediately after death, congregated in the blood, lymph glands, liver and suprarenals in pure cultures. These organs were the ones that showed the syphilitic changes in the most pronounced form. In two other children with congenital syphilis, as also in this one, the syphilitic changes in the organs were more marked than in adult syphilis. No spirochetes were found in the other non-syphilitic children examined. The syphilitic infants were from one to four weeks old, and in the hemorrhagic case the blood presented peculiar leukemic findings. All the organs and tissues seemed to have suffered from the action of the syphilitic toxin. Spirochetes were found in each of the three infants, and were most numerous at the points where the syphilitic changes were most apparent.

63. **Malignant Tumors in Mice.**—Ehrlich's experiences with 164 mice inoculated with malignant tumors revealed a number of interesting points. Out of 71 primary tumors only 10 proved transmissible, but with some of these none of the inoculations were failures. In one instance a carcinoma had been inoculated through several generations when suddenly a typical, spindle-celled sarcoma developed in the carcinoma, crowding out entirely the carcinoma cells. The sarcoma was inoculated further through 26 generations without modification in its elements. Simultaneous inoculation with carcinoma and sarcoma cells resulted in the production of a mixed tumor, but in succeeding generations the carcinoma elements always predominated more and more.

64. **Vaginal Ovariotomy.**—Reinecke quotes Pozzi's remark that Dührssen's vaginal Cesarean section was the last great achievement in surgery of the nineteenth century, and adds that he regards Dührssen's vaginal celiotomy as one of the most important triumphs in gynecology which that century produced. He gives the details of 5 cases in which he performed vaginal ovariotomy with extremely favorable results. Dührssen's vaginal fixation with silkworm, below the insertion of the tube, with isolated suture of the opening in the peritoneum between bladder and uterus, is the ideal fixation, he thinks. This isolated suture of the fold of peritoneum induces seroserous union which holds the uterus in antefixation while it does not interfere with its normal enlargement during a pregnancy. The threads are not removed for six weeks. It is certain, Reinecke concludes, that the former unfavorable attitude of many gynecologists is changing to a more favorable view as experience is demonstrating the advantages and the harmlessness of Dührssen's technic.

65. **Spirochetes in Ulcerating Carcinoma.**—Hoffmann has found spirochetes in three cases of this kind, but states that the spirilla differed in several respects from the *S. pallida* found in syphilitic lesions.

66. **Artificial Hyperemia in Treatment of Otitis.**—Heine is assistant at Lucae's ear clinic at Berlin, and here relates his experience with 19 cases of acute otitis media, with and without mastoiditis, treated by Bier's method of artificially induced hyperemia. This method of seeking to cure by artificially increasing the inflammation proved successful in the cases with abscess formation, but in the others it seemed to postpone the inevitable operation, and possibly to allow the best moment for intervention to pass. Out of the 19 cases 9 patients were entirely cured, in 2 the mastoiditis has apparently subsided, and in 8 an operation had to be done later. The congestion was induced by a rubber strap around the neck, only tight enough to induce a slight cyanotic, swollen appearance in the face. It was applied at 11 a. m., left for twenty-two hours, and replaced after an interval of two hours. The patients did not seem to mind it much after the first. In one case of mastoiditis, apparently requiring immediate operation, the patient has almost entirely recovered under this congestion treatment without further intervention.

67. **Treatment of Hypertrophied Prostate.**—Oberländer concludes his clinical lecture with the assertion that systematic evacuating catheterization has not only a symptomatic action, but is directly curative and generally wards off the necessity

for surgical intervention. He remarks that the proper choice of the catheter to use is the criterion of the result to be expected. Several catheters should be at hand, of from 14 to 15 Charrière and 40 cm. long. The Mercier curve is the best, not more than 130 to 150 degrees, and end in a cone rather than in an olive tip. On the slightest suspicion of a crack in the varnish the catheter should be discarded. The tip should always curve upward when being introduced. The great blunder is to catheterize at too long intervals. Four times a day generally suffices, supplemented by rinsing the bladder with a warm, saturated solution of boric acid.

68. **Essence of Gout.**—Kionka describes a number of interesting experiments on the origin and nature of gout which he has been conducting with Frey. He found degenerative processes constant in the liver and kidneys of mice fed exclusively on meat. He also noted the total absence of the glycocol-destroying, urea-forming ferment in the liver of gouty subjects. He does not believe that pathologic changes in the liver are necessary for the production of gout, but that functional disturbances must certainly exist. Functional disturbances in the liver are very liable to entail disturbances in the urea metabolism. The absence of the glycocol-destroying and urea-forming ferment in the liver may be congenital or may be the result of improper diet or of constitutional poisoning. The remedies which have proved useful in gout owe this property probably to their beneficial action on the functions of the liver. Colchicin and benzoic and salicylic acids are powerful cholagogues, and they thus improve the conditions of the circulation in the liver. This is also accomplished by certain purgatives, hydrochloric acid, etc. Benzoic, salicylic and quinic acids have a further beneficial action in that they bind the glycocol and thus prevent its exerting a precipitating action on the uric acid in the organism. The presence of glycocol with a large amount of urea entails precipitation of urates. When there is a gouty tendency, that is, a lack of glycocol-destroying ferment, urates are precipitated. This occurs in cartilage and in connective tissue when glycocol is generated in them by nutritional disturbances.

75. **Mixed Infection in Tuberculosis.**—Pick believes that mixed infection is very frequently the reason why a latent phthisis suddenly assumes a rapid, galloping form. It promotes destructive processes in the lungs, especially cavity formation, which is mainly the work of streptococci. The metabolic products resulting from mixed infection are liable also to injure the organism. The prognosis of mixed infection, therefore, differs from that of pure tuberculosis. In case of high fever, tuberculin treatment can do little, if any, good. In general treatment measures against the mixed infection are necessary, and he has seen good results from creosote and also from the salicylates in the febrile cases. When the strength permits, hydrotherapy can be used to advantage, especially packs. In case of tuberculosis of the serous membranes he states that he has derived benefit from rubbing green soap into the skin of the abdomen or breast.

79. **Infectious Idiopathic Purpura.**—Gerber reports two cases, one terminating fatally. They occurred with a brief interval in two inmates of the same house.

81. **Appendicitis.**—Clemm regards the appendix as a necessary reservoir for the intestinal bacteria, and hence does not favor its removal without great cause. He agrees with Robin that fully 98 per cent. of the cases of appendicitis terminate in recovery without appendicectomy. In treatment he advises rest on a hard mattress, with applications of heat to the part to soothe the inflammation and to help move the bowels. A hot sand bag or thermophore is placed under the part and a hot, soft linseed poultice is placed over it or a light thermophore. The patient is coaxed to take frequent swallows of hot Carlsbad water or physiologic salt solution, as hot as possible. No opium, purgatives or ice are used. After several hours the hot applications are suspended and a tablespoonful of green soap is worked into the skin, after which an alcohol compress is applied. No food is allowed for two days. Rapid recovery is the rule under this treatment in recent cases. The physician should continue his oversight of the case, with massage of the parts with his own hands, for weeks, and surveillance of the stools, supplemented by an adhesive-plaster supporting bandage and later a good truss, strengthening the muscles by appropriate exercise. Treatment on these principles will rob this dreaded disease of all its terrors, he affirms.

82. **Treatment of Cholelithiasis.**—Singer has been remarkably pleased with the results of olive oil in treatment of gallstones. In one of his cases a woman passed 52 gallstones, some as large as a cherry, under treatment with pure olive oil. He begins with one and increases to four or five tablespoonfuls a day, taken fasting, and followed by a small glass of warm Carlsbad water. Some patients overcome a repugnance to the taste by rinsing the mouth before and after with brandy or some alcoholic aromatic mixture. The oil can also be given in the form of a flavored emulsion. He sometimes uses an alkaline oleate in place of the oil, but has never had such success with it as with the olive oil. He generally advises gallstone patients to eat abundance of butter.

86. **Roentgen Examination of the Stomach.**—Holzknecht and Brauner add twenty-nine illustrations to their article emphasizing the value of the information that can be derived from Roentgen examination of the stomach after ingestion of a solution of bismuth. The fluid settles in the cracks and around the outside of a tumor and thus throws it into relief in the skiagram. The bismuth also outlines the stomach as the patient assumes various positions. No bougie or stomach tube is required. The views are taken standing and reclining, and during inspiration and expiration, the most important information being generally obtained by radioscopy. The findings are characteristic for the fasting stomach, and also for the stomach weighed down by a meal containing 500 gm. of food or inflated with gas. The size of the stomach and its relations to other organs can thus be accurately determined. The passage of a bismuth tablet into the stomach can be traced and its expulsion watched. The action of massage on the stomach can also be studied in this way, and the displacement of the organ during respiration. The diagnosis of cancer or hour-glass stomach is an easy matter by this means, and it also allows undisturbed supervision of the stomach peristalsis. To examine the standing patient the Roentgen tube and the fluorescent screen are suspended by weights from a wooden standard, parallel to each other. The patient swallows a tablet of bismuth and, after its course has been traced, drinks 50 gm. of water into which 10 gm. of bismuth have been stirred. After the findings of this test have been noted he drinks a mixture of 4 gm. tartaric acid and 5 gm. sodium bicarbonate. This stirs up the bismuth in the stomach and gives very interesting findings, after which the patient reclines and the findings in various positions are noted. The test on the following day consists of ingestion of 400 gm. of milk gruel containing 35 gm. bismuth. The patient takes this while reclining on the left side, with the Roentgen tube at his back, and he is then examined when lying on the right side and on his back. Specimens of the views thus obtained are reproduced.

88. Osmotic Tension of Stomach Content and Its Relation to the Proportion of Salt.—Strauss has been studying this subject for five years. The proportion of salt in the stomach content was found generally no higher than that of the blood. The secretory behavior of the stomach is of great import in respect to the proportion of chlorin in the stomach content, as it determines the amount of dilution of the solution isotonic with the blood. In case of defective secretory functioning there is little or no dilution, and hence the proportion of chlorin is abnormally high. In hyperacidity the secretion may be watery or concentrated. Admixture of saliva probably cooperates in causing the stomach content to be isotonic with the blood, but *it can not be the sole cause.*

89. Agglutination of Typhoid Bacilli in Proteus Infection.—Jochmann describes a case of otogenic general sepsis in which streptococci and proteus bacilli were cultivated from the blood. The serum had marked agglutinating action on typhoid bacilli as well as on the proteus.

90. Studies on Nephritis.—In this second installment Erben gives the details of chemical and other researches on the blood serum in 8 cases of contracted kidney and analyzes previous literature on the subject. He states that in parenchymatous nephritis, the proportion of globulin to albumin in the blood alters in favor of the former. The existing amyloidosis in some cases does not seem to change the quite constant composition of the red corpuscles, but it alters the composition of the serum and the relations between the corpuscles and the plasma. The increase in the extractive substances is due to the uremia.

92. Spinal Localization of Motor Functions.—Lazarus presents an array of data to prove that each anterior spinal root is a spinal center for certain combined muscle functions, several muscles working in synergy. These motor centers in the spine are localized the same as the centers in the cortex. Among the facts which he cites is the persistence of co-ordinated respiratory movements in animals after removal of the brain. He gives the localization by segments of the various motor functions in question, movements of head, neck, shoulder, trunk, etc., and the corresponding muscle groups and their centers in the spinal segments.

93. Comparative Tests of Blood Pressure Measurements.—The findings with the Hürthle tonograph and other instruments compared with those of the Riva-Rocci sphygmomanometer always paralleled each other in respect to the pulse pressure, that is, the difference between the minimum and maximum blood pressure, and the blood pressure quotient was found almost identical with each instrument. The sphygmomanometer is thus able to substitute the more complicated processes of determining the blood pressure in animals with a cannula.

94. Importance of Inorganic Salts in Metabolism.—Dogs were fed on a determined diet and the elimination of the waste carefully studied. The results indicate that it makes a great difference in what form the inorganic salts are ingested in respect to their assimilation. When phosphorus is given in the form of yolk of egg, the nitrogenous elements of the body make more rapid growth than when it is given in any other form. The yolk probably owes this property to its lecithin. This exhaustive research, therefore, scientifically confirms the general opinion in regard to the nourishig properties of yolks of eggs, and their early adaptability for the diet of children. A case of chronic deforming endocarditis was also studied from the point of view of the metabolism on various diets. The extensive work was done under a grant for scientific research, and presents a résumé of previous work in this line by various authors.

95. Influence of Alkalies on Degree of Acidity of Urine in Anemia.—Sodium citrate and sodium bicarbonate are able to render the urine alkaline in anemia. In some instances, however, especially in cases in which there is enlargement of the liver, this alkalinizing action is retarded for several days. On suspension of the alkali the urine becomes excessively acid, with increased secretion of ammonia and oxalic acid. Anemias without enlargement of the liver are accompanied by normal relations between the nitrogenized elements.

97. Protecting Functions of Omentum.—The protecting action of the omentum has been demonstrated by Cioffi's researches, not only for the spleen and kidney, but also for the liver, suprarenal capsules and intestines. If the vessels of the spleen are tied off and the omentum removed, the animal dies in twenty-four hours, while it survives longer if the omentum is left intact. If a flap of the liver is loosely tied off, the omentum covers and clings to it, with the result that a protecting capsule forms, with congregation of leucocytes and especially phagocytes. During this period of absorption of liver, spleen or other tissue, the kidney behaves in the same way as if organic nucleoproteids were being injected, that is, the secretory apparatus shows changes and there is parenchymatous hemorrhage. The protecting action of the omentum is promptest and most marked in case of lesions of the intestine.

99. Intravenous Route for Caffein and Strychnin.—Ferrannini's experimental researches have demonstrated that the drugs acting on the medulla can be administered intravenously in case of emergency.

101. Research on Leukemia and Pseudoleukemia.—Schupfer's article issues from Baccelli's clinic at Rome. He is convinced that leukemia has no analogy with ordinary infectious diseases, but is more in the nature of a systematic sarcomatosis of the lymph and blood producing organs. To demolish completely the idea that leukemia can be due to any ordinary micro-organisms and that they circulate in the blood, he injected cancer patients with blood from some patients with leukemia. The possible beneficial effect of an intercurrent infection justified the attempt, but the results were entirely negative, as they were in similar experiments on animals. These results, he thinks, disprove the possibility of an ordinary infectious agent, as cancer patients are peculiarly susceptible to mixed infections. Further experiments with inoculation of leukemic tissue, he thinks, have fully confirmed the assumption that leukemia is a sarcomatosis.

ABDOMINAL CRISES CAUSED BY MECKEL'S DIVERTICULUM.*

MILES F. PORTER, A.M., M.D.

Professor of Surgery and Clinical Surgery in the Fort Wayne College of Medicine.

FORT WAYNE, IND.

Within a period of two months during the latter part of the last year, there occurred in my practice four cases of Meckel's diverticulum.[1] In one of these cases, the diverticulum was the source of no trouble, but was met with during an operation for gunshot wound of the bowels. In the three other cases, the diverticulum was the occasion for the operation. This unusual experience aroused my interest in the subject and occasioned my determination to write the paper herewith presented.

The basis of the paper consists of my personal experience, a study of the literature of the subject and an analysis of the reports of 184 cases which I have tabulated and which includes 35 cases not hitherto reported. It is, of course, not pretended that this list is complete, but it comprises all the cases I could find in the literature available that were reported sufficiently in detail to fulfill my purpose in the study of the subject. Abstracts of many other cases were found, but they were too meager of detail to make their report worth while.

My purpose is to add, if possible, a little to the practical side of our knowledge on this subject, and therefore no attempt will be made in the direction of an exhaustive study of the embryologic, anatomic and pathologic phases of it. It is sufficient for our purpose to know that what we call Meckel's diverticulum is a fetal remnant of the intestinal tract, which in the normal course of events disappears by involution before birth; that because of an arrest of development it may remain as a patulous duct connecting the intestinal tract with the outer world via the umbilicus, or as a blind sac or cord connected to the umbilicus or to any other part of the abdominal walls or to any of the abdominal organs, or as a cul-de-sac unattached save at its origin; that it may have its origin in any part of the intestinal tract, but usually arises from the ileum[2]; that it may arise from any part of the circumference of the bowel, but usually arises opposite the mesenteric attachment; that histologically it agrees with the intestine, save in those cases wherein the involution has proceeded to such an extent as to leave only blood vessels and connective tissue.

Meckel's diverticulum is probably present in from 1 to 2 per cent. of all individuals. It is said by Halstead to be the cause of intestinal obstruction in 6 per cent. of all cases.[3] In my own list of 184 cases it caused obstruction by band in 101 cases; volvulus, intussusception, diverticulitis and other crises in 83 cases. The average age at which crises occurred, according to my table, is 21 years and 2 months, and yet this includes 6 patients over 50, 1 being 81 years of age. Judging from these facts, we are warranted in concluding that, in proportion to the frequency of its presence, Meckel's diverticulum is one of the most frequent sources of grave abdominal trouble, and, therefore, not as Kelynack and others think, of slight practical importance. A Meckel's diverticulum is a greater menace to life than is an appendix vermiformis.

A study of the different ways in which the diverticulum causes trouble is of much importance. From the list of cases here presented we find that it has caused obstruction of the bowel by a band (Figs. 1, 2, 3) in 101 cases, been the cause of volvulus in 8 cases, and of intussusception in 20 cases. Diverticulitis was the cause of the crisis in 17 cases, prolapse of the bowel through a patent diverticulum in 2 cases, typhoid perforation in 5 cases, traumatic perforation in 1 case, and tubercular ulceration in 2 cases. In the 21 cases of hernia reported in this paper, the diverticulum was the cause of the trouble demanding immediate operation in all but one (Figs. 4, 5); in that one it was simply noted as forming the content of the sac. The diverticulum is more often found in umbilical than in any other variety of hernia (Figs. 6, 7), and not infrequently it is found in congenital inguinal hernia, as pointed out by Bunts.[4] It may form the only content of the sac, a true hernia of the diverticulum, or it may occupy the sac in connection with other structures. That the existence in a hernia of a diverticulum adds materially to the danger of the case seems quite evident. Maylard,[5] quoting Hudson, mentions stricture of the gut from excessive obliteration of the diverticulum, but I found no other similar case reported, although Watson Cheyne[6] and others cite cases wherein stricture of the bowel has resulted from pathologic changes secondary to intussusception and other trouble originating in a diverticulum (Fig. 8). Fitz[7] in his paper cites cases of intramesenteric *diverticulum* (*Fig. 9*), and accounts for duplication of the intestine by the blind extremity of the diverticula thus located becoming attached to the intestinal wall, at which point communication is established by perforation (Figs. 10, 11). He also mentions the rare occurrence of branched diverticula cysts of the diverticulum form, and, in a few instances, have been the cause of the crisis. In one case in the list (Figs. 12, 13), the cyst produced volvulus, in one obstruction and gangrene of the bowel by traction, and in another the weight of a cyst developed in the free end of the diverticulum dragged it over a loop of bowel producing obstruction. In one case reported by Beach[8] the occasion for the operation was a pelvic tumor which proved to be a diverticulum filled with dried fecal matter.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] Since this paper was written a fifth case has occurred in my practice. It was met *during* an operation for obstruction of the bowels and was causing no trouble. See illustration.

[2] The name *diverticulum ilei* indicates that the origin of the diverticulum is always the ileum and is therefore incorrect.

[7] Am. Jour. of Med. Sciences, July, 1884.

In 5 cases the diverticulum was patent at the umbilicus. If the opening be large, the gut wall may prolapse and form the outer covering or sac of a hernia. Some of the numerous pathologic conditions produced and shapes assumed by Meckel's diverticulum, which have been observed, are herewith illustrated for the sake of clearness and brevity (Figs. 14, 15). To know the various locations, forms, attachments and pathologic changes which diverticula may present is important, in that the surgeon thus informed is in a sense forearmed. The most practical deduction from these facts seems to me to be, that, in the vast majority of cases of abdominal trouble due to Meckel's diverticulum, the trouble manifests itself primarily as a peritonitis or as an obstruction with or without strangulation (Figs. 16, 17, 18). The obstruction may be complete or incomplete throughout; or incomplete obstruction may be succeeded by complete obstruction. Symptoms of acute obstruction were manifest from the start in 118 cases. Incomplete obstruction was present throughout in 7 cases. In 17 cases there had been previous attacks of incomplete obstruction prior to the final attack of acute complete obstruction. In 20 cases, the symptoms were those of peritonitis, either circumscribed or general. In many cases the trouble was diagnosticated as appendicitis (Fig. 19), and in 1 case appendicitis existed as a complication in a case of strangulation of the bowel by the diverticulum, and in another (McArthur[9]) the appendix was gangrenous because of strangulation by a diverticulum acting as a band, the diverticulum itself being healthy. In cases of supposed appendicitis in which the conditions of the appendix when seen does not account for the symptoms, the probability of the existence of a diverticulitis should be borne in mind (Fig. 20). This point is illustrated in Keefe's case, in which a diagnosis of appendicitis had been made and on opening the abdomen the appendix was found adherent, but showing no evidence of recent inflammation. A further search revealed a mass of intestine adherent to a Meckel's diverticulum and producing obstruction. The adhesions were released and the diverticulum inverted. The patient recovered.

As in obstruction and strangulation of the bowel from other causes, so in those due to a diverticulum acting in a mechanical way, the symptoms of obstruction and strangulation are often followed by, or have added, symptoms of infection, i. e., peritonitis. In many cases the primary trouble is a diverticulitis with a subsequent formation of adhesions leading to obstruction. In these cases, of course, the symptoms of obstruction are preceded by symptoms of infection. In this class of cases the symptoms are very like those of appendicitis and this is the diagnosis usually made prior to operation.[10]

Of the cases here reported, the proportion of males to females is more than three to one, and the average age, as above stated, is 21 years and 2 months, so that while trauma is mentioned infrequently as an etiologic factor in the production of these crises, yet it would seem that the proponderance of males and the active period of life during which most cases occur would point to injury as among important causes (Fig. 21).

Oderfeld's case, reported by Halstead,[9] is the only one found in which a diagnosis was made prior to the operation. Just how the diagnosis was arrived at in this case does not appear quite clear.

As noted above, the symptoms arising in the crises due to Meckel's diverticulum, barring those patulous at the umbilicus, are in no way distinctive, but are similar to those met with in obstruction of the bowel by bands, in volvulus, in intussusception, in perforation and in appendicitis, etc., and hence a positive diagnosis without opening the abdomen is impossible, save in rare instances. An exact diagnosis, however, is not necessary before operating and to wait for it is neither good sense nor good surgery. All that is necessary before operating in these, as in similar cases, is what might be well termed a working diagnosis, and to wait for anything more is to sacrifice life. The frightful mortality which obtains in the cases under consideration, may be almost entirely attributed to delay in surgical interference. It seems to me that one of the most useful purposes that the reports appended can serve, is to emphasize the fact, well known among surgeons, that delay in operating is the most fruitful source of mortality and morbidity in surgical diseases.

In this list of 184 cases, the mortality is in all 60 per cent. Of all those patients operated on, the mortality is 50 per cent. While in the cases in which diagnoses of strangulated hernia and appendicitis were made, and in which, therefore, the patients were operated on early, as is the rule in these conditions, the mortality is 10 per cent. Words might preach a more eloquent sermon against delay in surgical intervention, but not a more powerful one.

To cover the subject of the operative technic would be to cover the subject as it concerns numerous pathologic conditions, the operative technic of which has been fully discussed. It is only necessary, therefore, to speak of the disposition of the diverticulum itself. To me it seems much better to excise it than to invert it. To invert it would mean partially to obstruct the lumen of the bowel, nor does it seem to me far-fetched to suppose that this disposition of it would invite ulceration invagination and perforation of the bowel.

After excision of the diverticulum the treatment of the opening will depend on the size of it and its relation to the lumen of the gut. When the opening is small, a single purse-string suture is simple, safe and sufficient; in other cases, Lembert sutures will be better; and in still others a portion of the bowel, including the diverticulum, will have to be removed to avoid stricture.

In conclusion I want to urge the advisability of removing all diverticula that are found in the course of abdominal operations, whether they have been or are the source of the trouble or not, provided the exigencies of the case in hand do not contraindicate further operative procedure.

SUMMARY OF TABULATED CASES.

Number of cases herewith reported for the first time, 35; total number of cases reported, 184; deaths, 93; recoveries, 67; results not stated, 24.

Patients operated on, 139; deaths, 65; recoveries, 65, result not stated, 9.

Patients not operated on, 18; deaths, 18.

Cases in which treatment is not mentioned, 27.

Kind of crisis: hernia, 21 cases; umbilical, 10; inguinal, 8; scrotal, 2; result not stated, 1.

Patients with hernia operated on, 11; recoveries, 6; deaths, 4; result not stated, 1.

Patients with hernia not operated on, 5; deaths, 5. Cases of hernia in which treatment is not stated, 5.

[10] Erdmann: The Journal A. M. A., Jan 21, 1905, p. 171.

Obstruction by band, 101 cases. Place of attachment of diverticulum, mesentery, 29; umbilicus, 22; free band about intestine, 9; to intestine, 11; brim of pelvis, 3; internal ring, 1; omentum, 1; diverticulum free, and acting as cyst, 2; stump of appendix, 1; mesorectum, 1; caught in loop of small intestine, 2; abdominal wall, 3; as band, place of attachment not stated, 16.

Volvulus, 8 cases; patients operated on, 7; deaths, 4; recoveries, 2; treatment not mentioned, 1

Intussusception, cases, 20; of bowel, 10; of diverticulum, 6; of bowel and diverticulum, 4. Patients operated on, 13; deaths, 8; recoveries, 5. Patients not operated on, 7; deaths, 4; result not stated, 3.

Patent at umbilicus, cases, 5; Patients operated on, 4; recoveries, 4; treatment not mentioned, 1; deaths, 1.

Diverticulitis, cases, 17; gangrenous, 6; deaths, 4; recoveries, 2. Due to presence of foreign body, 8; deaths, 7; result not stated, 1. Diverticulitis due to other causes, cases, 3. Number of cases of diverticulitis in which general peritonitis resulted, 8.

Perforation in typhoid, cases, 5; deaths, 5. Perforation from trauma, cases, 1; result not stated

Tubercular ulceration of diverticulum, cases, 2; deaths, 1; recoveries, 1.

Prolapse of bowel, cases, 2; deaths, 2.

Pelvic tumor, 1 case; recovery, 1.

Rupture of diverticulum causing obstruction from pressure of abscess, 1 case; result not stated. Summary: Males, 100; females, 30. Number of ages given, 137; result not stated, 54. Average age, 21 years, two months.

REPORTED CASES.

Case 1.—Dowse: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904.) Female, aged 27. Kind of crisis, direct inguinal hernia. Symptoms, a fecal fistula had formed owing to the collection of fecal matter in the diverticulum. Treatment, patient not operated on. Result, death. Remarks: At postmortem right direct inguinal hernia was found, in the sac of which the diverticulum was found adherent to the anterior wall of the sac. The diverticulum was ulcerated and perforated owing to accumulation of fecal matter within it, thus forming fistula in right groin.

Case 2.—Mueller: (Cited from Bunts, *Ann. of Surg.*, Oct. 1904.) Fetus, aged 8 months. Kind of crisis, umbilical hernia. The child was born dead, having umbilical hernia, the sac of which contained an adherent diverticulum.

Case 3.—Ahlfeld: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904.) Female, aged a few days. Kind of crisis, umbilical hernia. The child was born slightly prematurely, having an umbilical hernia, the sac of which contained a diverticulum two inches long, adherent to the umbilical ring. The child lived but a few days after birth.

Case 4.—Braus: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904.) Age, 7. Kind of crisis, umbilical hernia. Treatment, laparotomy; the diverticulum was excised. Result, not stated. Remarks: Tumor at umbilicus, on being opened revealed a diverticulum as the only content.

Case 5.—Gluck: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904.) Fetus born at 7 months. Kind of [illegible] symptoms consisted of signs of [illegible] Treatment, radical operation for [illegible] excised. Result, not stated. Rema[illegible] cessory mesenteric fold was found b[illegible] over the intestine.

Case 6.—Dunchamp: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904.) Age and sex not stated. Kind of crisis, umbilical hernia. Remarks: Umbilical hernia with thin covering, reducible, covering burst and the contents including a diverticulum flowed out.

Case 7.—Rosenblaum: (Cited from Bunts, *Ann. of Surg.*, Oct. 1904.) Age and sex not stated. Kind of crisis, umbilical hernia. Remarks: A Meckel's diverticulum was found during a radical operation for hernia.

Case 8.—Hallet. (Cited from Bunts, *Ann. of Surg.*, Oct. 1904.) Female, aged 2 hours. Kind of crisis, umbilical hernia. Treatment, laparotomy; the diverticulum was excised. Result, not stated. Remarks. Operation revealed the contents of the sac to be cecum, small intestine and a diverticulum.

Case 9.—Tiedeman: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904.) Child born at full term, few hours old. Kind of crisis, umbilical hernia. Remarks: On opening the hernial sac it was found full of yellowish fluid and communicating with the lumen of the intestine. Tiedeman thought this a true umbilical vesicle, but Roth regarded it as an enterocyst.

Case 10.—Carle: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904.) Age and sex not stated. Kind of crisis, umbilical hernia. Treatment, operation. Result not stated. Remarks: Umbilical tumor, hernia of Meckel's diverticulum was diagnosticated. Operation showed the sac to contain a small tumor pierced at the summit, out of which fecal matter exuded.

Case 11.—Benevoll: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904.) Age, not stated, male. Kind of crisis, scrotal hernia. The symptoms were th[illegible] Treatment, no operation. Result, death. [illegible] revealed a diverticulum extending into t[illegible] below the attachment not of a natural color.

Case 12.—Morgagni: (Cited from Bunts, *Ann. of Surg.*, Oct., 1905.) Male, aged 50. Kind of crisis, inguinal hernia. The symptoms were those of strangulation. Treatment, no operation. Result, death. Remarks: Postmortem revealed small process or diverticulum given off of the small intestine as it crossed the internal ring. The incarceration caused the obstruction.

Case 13.—Littre: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904.) Male, aged 48. Kind of crisis, scrotal hernia. Remarks: Diverticulum was found in the hernial sac.

Case 14.—Thompson: (Cited by Bunts, *Ann. of Surg.*, Oct., 1904.) Male, aged 50. Kind of crisis, inguinal hernia. Symptoms, the patient had some trouble occasionally with hernia. After prolonged attempt at reduction of the hernia, lasting about three hours, reduction was finally accomplished. The same night the patient showed symptoms of peritonitis and strangulation. Treatment, laparotomy. Result, death. Remarks: On opening the belly the cavity was found full of fecal matter and fluid. No perforation could be found in small intestine at operation. At autopsy a Meckel's diverticulum was found perforated at tip, and showing evidence of adhesion probably to sac of hernia.

Case 15.—Dungan: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904.) Child, male. Kind of crisis, inguinal hernia. The symptoms were those of strangulation. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The hernial sac contained coils of small intestine with a diverticulum wedged between them at the neck of the sac, making reduction by taxis impossible.

Case 16.—Banks: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904.) Age and sex not stated. Kind of crisis, hernia variety not stated. Character of symptoms not noted. Treatment, laparotomy; the diverticulum was excised with portion of small bowel. Result not stated. Remarks: The diverticulum is mentioned as being part of the contents of hernial sac.

Case 17.—Webster: (Cited from Bunts, *Ann. of Surg.*, Oct., 1904).) Female, aged 42. Kind of crisis, inguinal hernia. The symptoms were those of acute and complete strangulation. Treatment, laparotomy; the diverticulum was excised; Lembert sutures were used. Result, recovery. Remarks: The diverticulum had a well-defined lumen densely adherent in canal.

Case 18.—Buntz: (*Ann. of Surg.*, Oct., 1904). Male, aged 23. Kind of crisis, inguinal hernia. The symptoms were those of partial obstruction. Treatment, laparotomy; the diverticulum with portion of small intestine was resected, union by Murphy button. Result, recovery. Remarks: On opening the sac, a knuckle of constricted diverticulum was revealed. The diverticulum was gangrenous and the intestine was also gangrenous at point of origin of the diverticulum.

Case 19.—Karajan: (*Wiener klin. Wochft.*, 1901.) Male, aged 30. Kind of crisis, inguinal hernia. The symptoms were those of comp[illegible] ment, laparotomy; the diverticulum was [illegible] y. Remarks: The diverticulum was found [illegible] of the hernial sac. By this position it hel[illegible] small intestine in the sac.

Ca[illegible] (Personal communication.) Male, aged [illegible] were those of complete obstruction. Treat[illegible] for hernia. Result, recovery. Remarks: The diverticulum formed the content of the sac.

Case 21.—Moore: (The Journal A. M. A., Oct. 4, 1904.) Child, aged seven months. Kind of crisis, umbilical hernia: Symptoms, the child was weak, constantly crying and straining. Treatment, laparotomy; the hole in the tip of [illegible] with Lembert suture; the diverticulum [illegible] rwise because of condition of patient. [illegible] Umbilical protuberance w[illegible] up to the time of operation. Operation [illegible] as content of sac.

Case 22.—Jos. Bry[illegible] Surg. Soc., *Ann. of Surg.*, Jan., 1893.) Male, aged [illegible] Kind of [illegible] band. The symptoms were those of acute [illegible] ment, laparotomy; the inflated bowel was [illegible] edges stitched to edges of wound. Result, death. Remarks: The diverticulum was attached to the mesentery, constricting bowel as a band. The bowel was gangrenous.

Case 23.—Morton: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Female, aged 9. Kind of crisis, obstruction by band. The symptoms were those of appendicitis and partial obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was adherent to the umbilicus; a loop of bowel was caught under the band thus formed.

Case 24.—Hall: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 3. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the [illegible] xcised. Result, recovery. Remarks: The [illegible] ched to mesentery; a loop of bowel was [illegible] d.

[illegible] Sellers: (Cited from Halstead, *Ann. of* [illegible] e and sex: 32, male. Character of symptoms, those of acute obstruction Kind of crisis, obstruction by band. Treatment, laparotomy. Result, death. Remarks: Diverticulum attached to umbilicus, loop of ileum caught under band thus formed.

Case 26.—Sellers: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 32. Kind of cris[illegible] l. The symptoms were those of complete [illegible] laparotomy; the diverticulum was exci[illegible] marks: The diverticulum was attached to t[illegible] obstruction by kinking bowel by traction.

Case 27.—Fawcett: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Female, aged 11. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was attached to "bowel" ring constriction.

Case 28.—Snow: (Cited from Halstead, *Ann. of Surg.*, vol. 35.) Male, aged 3. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, no operation. Result, death. Remarks: At autopsy, the diverticulum was found attached to mesentery acting thus as a constricting ring.

Case 29.—Mackay: (Cited from Halstead, *Ann of Surg.*, vol. xxxv.) Young female. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the cord was divided. Result, recovery. Remarks: The diverticulum was attached to left to transverse colon, acting as band.

Case 30.—Hohlbeck: (cited from Halstead, Ann. of Surg., vol. xxxv.) Male, aged 4 years, 6 months. Kind of crisis, obstruction by band. The symptoms consisted of repeated attacks of pain and vomiting with a final attack of complete obstruction. Treatment, laparotomy; resection of portion of gut with diverticulum. Result, death. Remarks: The diverticulum was attached to omentum, thus producing obstruction by traction.

Case 31.—Hohlbeck: (Cited fro[illegible] vol. xxxv.) Female, aged 39. Kind of [illegible] The symptoms were those of comple[illegible] laparotomy; resection of portion of g[illegible] diverticulum; union with Murphy button. Result, recovery. Remarks: The diverticulum was free, knotted around intestine, thus causing stricture.

Case 32.—Symonds: (Cited fr[illegible] *Surg.*, vol. xxxv.) Female, aged 15. Kind of [illegible] band. The symptoms were those of comple[illegible] ment, laparotomy. Result, death. Remar[illegible] was adherent to gangrenous intestine, thus causing constriction.

Case 33.—Symonds: (Cited fro[illegible] vol. xxxv). Female, aged 26. Kind of [illegible] The symptoms were those of complete [illegible] laparotomy. Result, death. Remarks: "Gut folded around very wide diverticulum."

Case 34.—Schmidt: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 15. Kind of crisis, obstruction by band. The symptoms were those of partial obstruction. Treatment, laparotomy. Result, death. Remarks: The diverticulum was attached to the umbilicus, thus producing obstruction by kinking bowel from traction.

Case 35.—Berard and Delore: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 20. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was attached to the umbilicus; there was obstruction of ileum and adhesion of loops.

Case 36.—Bell: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Female, aged 16. Kind of crisis, obstruction by band; symptoms were those of complete obstruction. Treatment, laparotomy. Result. Recovery. Remarks: The diverticulum was attached to the umbilicus, thus kinking the bowel from traction.

Case 37.—Nedivill: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Female, aged 16. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy, "cord divided." Result, recovery. Remarks: The diverticulum was attached to the umbilicus, a loop of bowel was caught under band thus formed.

Case 38.—Carle and Chevet: (Cited from Halstead, *Ann. of Surg.*, vol xxxv.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was attached to the mesorectum; a loop of bowel was caught under this band.

Case 39.—De Gueovain: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 16. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: A pear-shaped diverticulum was attached to the mesentery, producing a twist in the small intestine at the point of origin of the diverticulum by traction.

Case 40.—Kammerer: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 20. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, the diverticulum was removed with gangrenous bowel. Result, death. Remarks: The diverticulum was attached to a loop of bowel; another loop was caught under this band.

Case 41.—Kammerer: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 44. Kind of crisis, obstruction by band. The symptoms consisted of obstruction with fecal fistula. Treatment, laparotomy; the diverticulum was excised. Result, recovery, with fecal fistula. Remarks: The diverticulum was attached to the umbilicus, thus producing obstruction from traction. At the first operation an artificial anus was established. The diverticulum was found at second operation.

Case 42.—Kammerer; (Cited from Halstead, *Am. of Surg.*, vol. xxxv.) Female, aged 18. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the cord was divided. Result, recovery. Remarks: The diverticulum was attached to the mesentery, acting as a band under which a loop of bowel became strangulated.

Case 43.—Thompson: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 29. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Lembert sutures were used. Result, death. Remarks: The diverticulum was attached to mesentery, acting as band.

Case 44.—Erdmann: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 20. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction complicated with appendicitis. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was attached to the umbilicus; a loop of bowel was caught under the band thus formed.

Case 45.—Halstead: (*Ann. of Surg.*, vol. xxxv.) Male, aged 24. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. The history showed several previous attacks of pain. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was attached to root of mesentery, thus acting as a band.

Case 46.—Taylor: Trans. Phila. Academy of Surg., *Ann. of* Surg., vol. xxxvii.) Female, aged 20. Kind of crisis, obstruction by band. The history showed previous attacks of pain about one year previous to operation; the later symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum wound around the gut through a hole in the mesentery, thus acting as constricting band.

Case 47.—Gildersleeve: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 29. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, patient was not operated on. Result, death. Remarks: The diverticulum was attached to mesentery; the gut was caught under this band.

Case 48.—Fox: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 5. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, patient was not operated on. Result, death. Remarks: The diverticulum was attached to the mesentery, acting as band; the diverticulum had ruptured at base.

Case 49.—Heresco: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy, the cause of strangulation was not found. Result, death. Remarks: Autopsy revealed the diverticulum attached to the mesentery; a loop of bowel was caught under this band.

Case 50.—Jordan: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 19. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; a portion of the gut was resected, lateral anastomosis. Result, death. Remarks: The diverticulum was attached to the umbilicus, causing obstruction by traction; the bowel was gangrenous.

Case 51.—Latz: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 4. Kind of [illegible] d. The symptoms were those of complete [illegible] laparotomy. Result, death. Remarks: [illegible] attached to the mesentery; the bowel was caught under this band.

Case 52.—Latz: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Female, aged 12. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, death. Remarks: The diverticulum was attached to the mesentery; the gut was caught under this ring.

Case 53.—Broca: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 7 weeks. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the gut was released. Result, death. Remarks: The diverticulum was attached to the mesentery; the gut was caught under band thus formed.

Case 54.—Elliot: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 30. Kind of crisis, obstruction by band. Treatment, laparotomy; the diverticulum was excised. Result, death. Remarks: The diverticulum was attached to the umbilicus; the gut had kinked and twisted at point of origin of diverticulum.

Case 55.—Councilman: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, not mentioned. Result, death. Remarks: Autopsy revealed a diverticulum attached to the mesentery under which a loop of bowel became caught and gangrenous.

Case 56.—Boyle: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Age and sex not mentioned. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; "constriction removed." Result, death. Remarks: The diverticulum was attached to umbilicus, loop of bowel was caught under this tensely drawn band.

Case 57.—Ochsner: (Cited from Halstead, *Ann of Surg.*, vol. xxxv.) Male, aged 81. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy, the loop was disengaged. Result, death. Remarks: The diverticulum was attached to the mesentery; a loop of bowel was caught under band thus formed.

Case 58.—Prince: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Female, aged 4. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; a portion of gut was resected, including diverticulum; union by Murphy button. Result, death. Remarks: The diverticulum was attached to the mesentery, a loop of bowel was caught under the band thus formed.

Case 59.—Oderfeld: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was attached to the mesentery; a loop of gut was caught under this band. This case was diagnosticated as obstruction by Meckel's diverticulum before operation.

Case 60—Zurnrinkle: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 19. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, death. Remarks: The diverticulum was attached to the mesentery; a loop of bowel caught under this band thus formed.

Case 61.—Allen: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 34. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, not mentioned. Remarks: The diverticulum was attached to the umbilicus; the gut was twisted about this band.

Case 62.—Prendelsberge: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 51. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy. Result, death. Remarks: Cause of obstruction was not found at operation. Autopsy revealed a diverticulum attached to mesentery acting as a band in constricting the bowel.

Case 63.—Taylor: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 22. Kind of crisis, obstruction by band. Treatment, laparotomy; "gut released." Result, death. Remarks: The diverticulum was attached to the gut for one and one-half feet above its origin; a loop of gut was caught under this band.

Case 64.—Campbell: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 71. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, patient was not operated on. Result, death. Remarks: (Autopsy) the diverticulum was free, acting as a band.

Case 65.—Walsberge: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 25. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; "gut released." Result, death. Remarks: The diverticulum was free—ends obliterated; there was obstruction by traction at point of origin of diverticulum; diverticulum formed a cyst; the intestine was necrotic.

Case 66—Mlutz: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 24. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, no operation. Result, death. Remarks: (Autopsy) The diverticulum was attached to the mesentery; a loop of bowel was caught under this band.

Case 67.—Willams: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 25. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy. Result, death. Remarks: The diverticulum was attached to the mesentery; a loop of bowel was caught under this band.

Case 68.—Morgan: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 38. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was attached to the mesentery; a loop of bowel was caught under this band.

Case 69.—McArthur: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 40. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the appendix and diverticulum were excised. Result, death. Remarks: The diverticulum was attached to the mesentery and to the umbilicus; the appendix was caught under this tensely drawn band, becoming gangrenous. There was rupture of the appendix with peritonitis.

Case 70.—Henrotin: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; strangulation was released. Result, recovery. Remarks: The diverticulum was attached to stump of appendix by inflammatory adhesions; the intestine was twisted and obstructed.

Case 71.—Davison: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 7. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy: strangulation was released. Result, death. Remarks: The diverticulum was attached to another loop of intestine.

Case 72.—Bevan: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Female, aged 22. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was attached to the umbilicus, thus acting as a band.

Case 73.—Bevan: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 35. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks The diverticulum with terminal ligament formed a ring.

Case 74.—Pieque: (*Munch. med. Wochft.*, May, 1898.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of acute complete obstruction. Treatment, laparotomy; the diverticulum was cut between ligatures. Result, not stated. Remarks: The diverticulum encircled the intestine, crooking it.

Case 75.—Keefe: (*Boston Med. and Surg. Jour.*, Feb., 1905.) Male, aged 21. Kind of crisis, obstruction by band. The symptoms were those of acute complete obstruction. Treatment, laparotomy. the diverticulum was excised, stump inverted, and Lembert sutures used. Result, recovery. Remarks: The diverticulum was wound around the intestine.

Case 76.—Keefe: (*Boston Med. and Surg. Jour.*, Feb., 1905.) Male, age 17. Kind of crisis, obstruction by band. The symptoms were those of complete obstruction. Treatment, laparotomy: the diverticulum was excised: Lembert sutures were used. Result, death. Remarks: The diverticulum was adherent to coils of intestine.

Case 77.—Karajan: (*Wiener klin. Wochft.*, 1901.) Male, aged 20. Kind of crisis, obstruction by band. When young, the patient had a fistula opening at the umbilicus, which would heal and break again. When taken to the hospital he had been suddenly taken with pain and vomiting. Treatment, laparotomy. The diverticulum was excised. Result, recovery. Remarks: The diverticulum was attached to the umbilicus, acting as band.

Case 78.—Karajan: (*Wiener klin. Wochen.*, 1901.) Male, aged 38. Kind of crisis, obstruction by band. The patient had had similar atta[illegible]sent one of acute obstruction. Treatment, [illegible] rticulum was excised. Result, death. Rem[illegible] was attached to posterior abdominal wall, acting as band.

Case 79.—Thienhaus: (*New York Med. Jour.*, February, 1902.) Male, aged 17. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy. The diverticulum was excised. Czerny-Lembert sutures were used. Result, recovery. Remarks: The diverticulum was attached to the umbilicus: a loop of bowel was caught under band thus formed.

Case 80.—Roswell Park: (Personal communication.) Male, aged 40. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy. Result, recovery. Remarks: The diverticulum was adherent, acting as a band.

Case 81.—W. J. Mayo: (Personal communication.) Male, aged 14. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. There was a history of similar previous attacks. Treatment, laparotomy. Result, not mentioned. Remarks: The diverticulum was adherent, acting as a band.

Case 82.—W. J. Mayo: (Personal communication.) Male, aged 26. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. There was a history of similar attacks previous to operation [illegible]. Result, not mentioned. Remarks: The [illegible] t, acting as a band.

Case 83.—Senn: [illegible] Age and sex not mentioned. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy. The diverticulum was excised. Result, recovery. Remarks: The diverticulum was adherent, acting as a band.

Case 84.—Senn: (Personal communication.) Age and sex not mentioned. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy. The diverticulum was excised. Result, recovery. Remarks: The diverticulum was adherent, acting as a band.

Case 85.—B. M. Ricketts: (Personal communication.) Male, aged 27. Kind of crisis, obstruction by band. The symptoms were those of partial obstruction. Treatment, laparotomy, resection of ileocecal portion of bowel and ileocolic anastomosis with sutures. Result, death. Remarks: Incision revealed tuberculous peritonitis. The ileocecal valve was the seat of a tuberculous neoplasm. The ileum was invaginated under a band extending from the ileum to the colon on the right side.

Case 86.—Ricketts: (Personal communication.) Male, aged 32. Kind of crisis, obstruction by band. The symptoms were those of partial obstruction. Treatment, laparotomy. The band was cut between ligatures. Result, death. Remarks: The diverticulum was adherent to the large bowel, acting as a band under which the gut became invaginated.

Case 87.—Ricketts: (Personal communication.) Female, aged 39. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy. The diverticulum was cut between ligatures. Result, death. Remarks: The diverticulum was adherent, acting as a band.

Case 88.—Dunning: (Personal communication.) Young female. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction, coming on after pelvic trouble. Treatment, laparotomy. A portion of bowel with diverticulum was resected; union by Murphy button. Result, recovery. Remarks: The diverticulum was adherent, causing constriction and kinking of bowel at point of origin.

Case 89.—Rob Abbe: (Personal communication.) Age, 6; sex not stated. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, a portion of bowel with diverticulum was resected: end-to-end anastomosis. Result, recovery. Remarks: The diverticulum was adherent to the anterior abdominal wall; a loop of bowel was caught under this band.

Case 90.—M. D. Mann: (Personal [illegible] age, 35. Kind of crisis, obstruction by [illegible] were those of acute obstruction; there was [illegible] attacks of intestinal colic. Treatment, [illegible], the obstruction was released. Result, recovery. Remarks: The diverticulum was adherent to the small intestine, forming a band under which the gut became strangulated.

Case 91.—Purviance: (*Medical Summary*, April 1901.) Male, aged 9. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy. Result, death. Remarks: The diverticulum was attached to the umbilicus, acting as a band under which the gut became strangulated.

Case 92.—Sexton: (*Indiana Med. Jour.*, December, 1902.) Male, aged 9. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction: there was a history of symptoms of partial obstruction. Treatment, laparotomy. Result, death. Remarks: The diverticulum was adherent to the intestine almost at point of origin, forming a ring under which the bowel was caught.

Case 93.—Cazin: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 11. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy; obstruction relieved. Result, death. Remarks: The diverticulum was unattached, "snared loop of intestines."

Case 94.—Gibbon: (*Med. News*, vol. lxxxii.) Female, aged 10. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was adherent to the umbilicus, producing obstruction by kinking the bowel from traction.

Case 95.—Chassevant: (Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, patient was not operated on. Result, death. Remarks (autopsy): The diverticulum was attached to the umbilicus, thus kinking of the bowel by traction.

Case 96.—Guinard: Cited from Halstead, *Ann. of Surg.*, vol. xxxv.) Young, male. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy. Result, recovery. Remarks: The diverticulum was attached to the mesentery, thus constricting the bowel.

Case 97.—Rixford: (Personal communication.) Aged 3. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy: the diverticulum was excised. Result, recovery. Remarks: There was a diverticulum from the umbilicus to the intestine, with a band to the mesentery: the cecum and colon became strangulated under this band.

Case 98.—MacDonald: (Personal communication.) Age, 30, male. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy. Result, death. Remarks: The diverticulum was adherent in pelvis; the gut caught under this band.

Case 99.—Willy Meyer: (Personal communication.) Male, aged 45. Kind of [illegible] and. The symptoms were those of acute [illegible] laparotomy: the diverticulum was excis[illegible] marks: The diverticulum from intestine [illegible] erent to mesentery, acting as a band.

Case 100.—Lilienthal: (Personal communication.) Female, aged 7. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy, enteroenterostomy: the diverticulum was excised at tip. Result, death. Remarks: The diverticulum was the caliber of the small intestine with a terminal nipple-like projection, which was fished out from behind a fold of mesentery, which for some inexplicable reason seem to have constricted its base.

Case 101.—Tiffany: (Personal communication.) Male. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy. Result, death. Remarks: The diverticulum was caught in loop of small intestine and had become gangrenous.

Case 102.—Moore: (The Journal A. M. A., Oct. 4, 1902.) Male, aged 4. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy; the band was divided between ligatures. Result, recovery. Remarks: The sudden onset of symptoms gave rise to a diagnosis of obstruction by Meckel's diverticulum. The diverticulum was found attached to the mesentery and constricting the bowel.

Case 103.—Abbot: (Cited by Moore, The Journal A. M. A., Oct. 4, 1902.) Male, aged 19. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy: the diverticulum was excised. Result, recovery. Remarks: The diverticulum was attached to the umbilicus; a loop of bowel was caught under the band thus formed.

Case 104.—Greig Smith: (*Abdominal Surg.*, vol. ii.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy; the band was cut. Result, recovery.

Case 105.—Greig Smith: (*Abdominal Surg.*, vol. ii.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy: the diverticulum was excised and the stump inverted; purse-string sutures were used. Result, not stated.

Case 106.—Maylard: ("Surgery of the Alimentary Canal," p. 462.) Male, aged 4. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, no operation. Result, death. Remarks: The diverticulum was attached to the mesentery; a loop of bowel was caught under this band.

Case 107.—Butcher: (Cited by Maylard, "Surgery of the Alimentary Canal," p. 462.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy; the band was divided. Result not stated.

Case 108.—Fick: (Cited by Maylard, "Surgery of the Alimentary Canal," p. 462.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment not stated. Result not stated.

Case 109.—Gillette: (Personal communication.) Male, aged 40. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction; there was a history of previous attacks of partial obstruction. Treatment, laparotomy: the diverticulum was excised. Result, recovery. Remarks: The diverticulum was attached to the mesentery; a loop of bowel was caught under this band.

Case 110.—Gillette: (Personal communication.) Male, aged 22. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction; there was a history of previous attacks of partial obstruction. Treatment, laparotomy; the diverti-

-culum was excised. Result, recovery. Remarks: The diverticulum was attached to the brim of the pelvis; a loop of bowel was caught under the band thus formed.

Case 111.—Bernays: (Personal communication.) Male, aged 7. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy; the band was cut between ligatures. Result, recovery. Remarks: The diverticulum was attached to the umbilicus; a loop of bowel was caught under this band.

Case 112.—Wyman: (Personal communication.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy; the obstruction was released. Result, recovery. Remarks: The diverticulum was wound about a coil of intestine.

Case 113.—Wyman: (Personal communication.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy; the obstruction was released. Result, recovery. Remarks: The diverticulum was wound about a coil of intestine.

Case 114.—Wyman: (Pers [illegible] and sex not stated. Kind of crisis, [illegible] ymptoms were those of acute obstruct [illegible]; the diverticulum was excised. Re [illegible] *diverti*culum was wound about the [illegible]

Case 115.—Wyman: (Personal communication.) Age and sex not stated. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy; the diverticulum was excised. Result, death. Remarks: The diverticulum was wound around the intestine.

Case 116.—C. C. Smith: (*Ann. of Surg.*, November, 1905.) Male, aged 19. Kind of crisis. obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy; the band was cut between ligatures and the stump inverted; a purse-string suture was used. Result, recovery. Remarks: The diverticulum was adherent to left pelvic wall; a loop of bowel was caught under this band. The diverticulum also was twisted on itself.

Case 117.—Markoe: (Personal communication.) Male, aged 22. Kind of crisis, obstruction by ban [illegible] those of acute obstruction. Treatment, [illegible] culum was excised and stump inverte [illegible] marks: The diverticulum was adherent to the internal ring, acting as a band.

Case 118.—Markoe (Personal [illegible] ale, aged 19. Kind of c [illegible] were those of acute [illegible] diverticulum was excise [illegible] arks: The diverticulum was adherent to the mesentery, acting as a band.

Case 119.—Bowers: (Personal communication.) Female, aged 7. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment. no operation. Result, death. Remarks (autopsy): The diverticulum was adherent to the mesentery, producing kinking of bowel by traction.

Case 120.—Beavers: (Personal communication.) Male, aged 21. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction; no operation. Result, death. Remarks: The diverticulum was adherent to the anterior abdominal wall, and had become gangrenous by stretching and twisting; a loop of bowel had become strangulated under this band.

Case 121.—Allan H. Williams: (Personal communication.) Male, aged 38. Kind of crisis, obstruction by band. The symptoms were those of acute obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was adherent to the small gut; a loop of bowel was caught under this band. After operation, a fistula formed which healed spontaneously.

Case 122.—M. F. Porter: (Date of operation, Oct. 17, 1904.) Male, aged 19. Kind of crisis, obstruction by band with volvulus. The symptoms were those of acute complete obstruction. Treatment, laparotomy; the diverticulum was excised; a purse-string suture was used. Result, death. Remarks: The diverticulum was adherent to the left abdominal wall.

Case 123.—M. F. Porter: (Operation, Oct. 11, 1904.) Male, aged 8. Kind of crisis. obstruction by band. The symptoms were those of acute complete obstruction. Treatment, laparotomy; the diverticulum was excised: purse-string sutures were used. Result, recovery. Remarks: The diverticulum was found adherent to the upper and left part of anterior abdominal wall; under it a loop of bowel had become strangulated.

Case 124.—Arthur Barth: (*Ann. Surg.*, vol. viii.) Age and sex not given. Kind of crisis, prolapse of intestine. Symptoms not menti [illegible] rticulum was excised: Cze [illegible] marks: Patulous diverticul [illegible] of intestine.

Case 1[illegible] Child, aged 10 days. Ki [illegible] atment, artificial anus esta [illegible] excised at second oper [illegible] Bowel was prolapsed fr [illegible] as also protruding. An [illegible] of the contracted state of the lower bowel.

Case 126.—Beach: (*Ann. of Surg.*, vol. xxiv.) Female, aged 62. Kind of crisis, pelvic tumor, consisting of a diverticulum filled with hardened fecal material, connecting ileum and bladder. Treatment, laparotomy: the tumor was excised between ligatures. Result, recovery. Remarks: The best explanation of the cyst was that it was a Meckel's diverticulum; this was based on histologic [illegible]

Cas [illegible] nd Blanc: (Cited from Halstead, *Ann. of Su*[illegible] Kind of crisis, bowel obstruction. The symptoms were those of complete obstruction. Treatment laparotomy; the diverticulum was excised. Result, unknown. Remarks: *Obstruction was caused* by rupture of diverticulum and pressure of abscess on gut.

Case 128.—W. W. Cheyne: (*Ann of Surg.*, December, 1904.) Male, aged -9. Kind of crisis, intussusception. The symptoms were those of complete obstruction. *Treatment*, laparotomy; lateral anastomosis. Result, recovery. Remarks: The bowel was obstructed by intussusception above origin of diverticulum.

Case 129.—Studgaard: (Cited by Cheyne, *Ann. of Surg.*, December, 1904.) Male, aged 37. Kind of crisis, intussusception. The symptoms were those of complete obstruction. Treatment, laparotomy; resection of portion of bowel. Result, death. Remarks: The diverticulum was invaginated.

Case 130.—Brunner: (Cited by Cheyne, *Ann. of Surg.*, December, 1904.) Child, aged 4. Kind [illegible] The symptoms were those of complete [illegible] laparotomy; resection of portion of [illegible] Remarks: A firm tumor was expose [illegible] ng an accessory pancreas at apex imbedded in fat. The diverticulum was invaginated by the accessory pancreas, which in turn had caused intussusception of the bowel.

Case 131.—Heller: (Cited by Cheyne, *Ann. of Surg.*, December, 1901.) Age and sex not stated. Kind of crisis, intussusception of diverticulum. Symptoms not stated. Remarks (report from specimen): There was invagination of the diverticulum leading to intussusception of the ileum and colon.

Case 132.—Heller: (Cited by Cheyne, *Ann. of Surg.*, December, 1904.) Age 46. Kind of crisis, intussusception of diverticulum. Remarks (report of specimen): Patient died from the effects of perforating ulcer of stomach. Autopsy revealed an invaginated diverticulum.

Case 133.—Heller: (Cited by Cheyne, *Ann of Surg.*, December, 1904.) Age and sex not stated. Kind of crisis, invagination of diverticulum. Remarks: At autopsy of a patient who died of pyoneph [illegible] erticulum was found.

Case [illegible] Cheyne, *Ann. of Surg.*, December, 1904.) [illegible] crisis, intussusception of diverticulum. [illegible] those of complete obstruction. Treatme [illegible] death. Remarks: The diverticulum [illegible] bowel.

Case [illegible] y Halstead, Ann. of Surg., vol. xxxv.) Female, aged 42. Kind of crisis, intussusception of diverticulum. The symptoms were those of partial obstruction. Treatment, no operation. Result. death. Remarks (autopsy): There was inflammatory stenosis above the point of origin of the diverticulum; the diverticulum was inverted; there was perforation of the intestine.

Case 136.—Weil and Frankel: (Cited by Halstead, *Ann. of Surg.*, vol. xxxv.) Female, aged 4. Kind of crisis, intussusception of diverticulum and ileum. The symptoms were those of complete obstruction. *Treatment*, laparotomy; resection of portion of bowel. Result, death.

Case 137.—Adams: (Cited by Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 42. Kind of [illegible] The symptoms were those of complete [illegible] no operation. Result, death. Remarks: [illegible] of the diverticulum, causing an ileocoli[illegible]

Case 138.—Adams: (Cited by Halstead, *Ann. of Surg.*, vol. xxxv.) Male. *Kind of crisis*, intussusception. *The symptoms* were those of complete obstruction. Treatment, no operation. Result, death. Remarks: The diverticulum was invaginated, causing ileocolic intussusception.

Case 139.—Hohlbeck: (Cited by Halstead, *Ann of Surg.*, vol. xxxv.) Age, 18. Kind of [illegible] symptoms were those of complete [illegible] arotomy; [illegible] excised. [illegible] *There was inversion of the mucous lin*[illegible] causing intussusception of bowel.

[illegible] (Cited by Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 5. Kind of crisis, intussusception. The symptoms were those of complete obstruction. Treatment, laparotomy, resection of portion of bowel. Result, death. Remarks: There was inversion of diverticulum with invagination of the bowel above the diverticulum.

Case 141.—Wainwright: (*Ann. of Surg.*, vol. xxxv.) Male, aged 24. Kind of [illegible] mptoms were those of complete [illegible] omy: the intussusception was [illegible] xcised; Lembert sutures were u [illegible]: The diverticulum formed the a [illegible] diverticulum itself being inverte[illegible] the intussusception was reduced on pressure.

Case 142.—*MacDonald*: (Personal communication.) Male, aged 20. Kind of crisis, intussusception. The symptoms were those [illegible] Treatment, laparotomy: resection of [illegible] bowel: union by Murphy button. Re[illegible] There was intussusception of the di[illegible] um

[illegible] (*Phila. Med. Jour.*, May, 1901.) Male. [illegible] intussus[illegible] on. *Trea*[illegible] death. Remarks (autopsy): The [illegible] itself and partly invaginated into t[illegible]

Case 144.—M. F. Porter: (Operation, Oct. 2, 1904.) Male, aged 3. Kind of crisis, intussusception. The symptoms were those of complete obstruction. Treatment, laparotomy. Result, death. Remarks: The child was cold when carried to the table. The diverticulum was invaginated, causing intussusception of ileum.

Case 145.—Dobson: (*Lancet*, April 25, 1903.) Male aged 4½. [illegible] were those of [illegible] gut was re[illegible] Result, re[illegible] apex of in[illegible]

Case 146.—[illegible] Halstead, *Ann of Surg.*, vol. xxxv.) *Female, aged* 49. Kind of crisis, intussusception. The diverticulum formed the apex [illegible] vel.

Case 147.—Stubenrauch: [illegible] *nn. of Surg.*, vol. xxxv.) Female, aged 5[illegible] tussusception. The symptoms were those o [illegible] Treatment. laparotomy. Result, death. [illegible] ntussusception of the ileum starting at the p[illegible] erticulum.

Case 148.—Meyer and Lee: (*Amer. Jour. Med. Sciences*, March, 1905.) Age, 7 months. Kind of crisis, volvulus. The symptoms were those of acute obstruction. Treatment, laparotomy; the diverticulum was excised. Result, death. Remarks: The diverticulum formed a large cystic tumor which by traction produced twist in bowel.

Case 149.—Gally and Jeannel: (Cited by Halstead, *Ann. of Surg.*, vol. xxxv.) Male, aged 47. Kind of crisis, volvulus. The symptoms were those of acute obstruction. Treatment, laparotomy: *resection of gangrenous bowel*. Result, death. Remarks: The volvulus of the bowel was caused by traction at point of origin of diverticulum; the bowel was gangrenous.

Case 150.—Dugan: (*Pediatrics*, vol ii, p. 71.) Male, aged 11 months. Kind of crisis, volvulus. The symptoms were those of acute obstruction. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The gut was twisted at the point of origin of the diverticulum; the diverticulum was also twisted at its base.

Case 151.—Makins: (Cited by Halstead, *Ann of Surg.*, vol. xxxv.) Age and sex not stated. Kind of crisis, volvulus. The symptoms were those of acute obstruction. Treatment, laparotomy; the diverticulum was excised. Result, death. Remarks: The diverticulum was twisted, *gangrenous and perforated.*

Case 152.—Mackenzie: (Cited by Halstead, *Ann of Surg.*, vol. xxxv.) Male, aged 37. Kind of crisis, volvulus. The symptoms were those of acute obstruction. Treatment, no operation. Result, death. Remarks: The diverticulum was attached to the umbilicus; the small bowel was twisted for five feet above the point of origin of the diverticulum.

Case 153.—Waisberge: (*Cited by Halstead, Ann. of Surg.*, vol. xxxv.) Male, aged 14. Kind of crisis, volvulus. The symptoms were those of acute obstruction. Treatment, *laparotomy; an artificial anus was established*; the diverticulum was not excised. Result, death. Remarks (autopsy): The distended diverticulum was adherent to the umbilicus; torsion of diverticulum caused sharp twist at point of origin of diverticulum in gut; the intestine was *necrotic.*

Case 154.—Taylor: (Cited by Halstead, *Ann of Surg.*, vol. xxxv.) Female, aged 6. Kind *of crisis, volvulus.* The symptoms were those of acu[illegible] a history of several previous similar [illegible]rotomy; the diverticulum was excise[illegible]arks: The diverticulum was cystic a[illegible] base.

Case 155.—Kra[illegible] *Ann. of Surg.*, vol xxxv.) Male, age[illegible]ulus. The symptoms were those of acute *obstruction. Treatment, laparotomy*; the diverticulum was excised. Result, recovery. Remarks: A pear-shaped diverticulum was adherent to the *mesentery; the small* intestine was twisted at the point of attachment.

Case 156.—Broca: (Cited by Hubbard, *Ann of Surg.*, vol. xxxv.) *Male, aged 6 months.* Kind of crisis, patent at umbilicus. Treatment, laparotomy; resection of diverticulum. Result, recovery. Remarks: There was a *small red tumor a*[illegible] which a probe could be passed for some [illegible] membrane around the orifice was continuous

Case 157.—Broca: (Cited by Hubbard, *Ann. of Surg.*, vol. xxxv.) Male, aged 10 months. Kind of crisis, patent at umbilicus. Treatment, laparotomy. Resection of diverticulum. Result, recovery. Remarks: There was a small red tumor at the umbilicus [illegible] hole at summit of tumor.

Case [illegible] by Hubbard, *Ann. of Surg.*, vol. xxxv.) [illegible] crisis, *patent at umbilicus.* Treatment, *laparotomy*; resection of diverticulum. Result, recovery. Remarks: There was a red tumor at the umbilicus, with fecal discharge from a hole in summit.

[illegible] *n. of Surg.*, vol. xxxv.) Female, aged [illegible] patent at umbilicus. Treatment, lap[illegible] was excised; two rows of Lembert [illegible] *recovery. Remarks:* There was a [illegible] bilicus, with fecal discharge from a hole in the summit.

Case 160.—Bird: (*Ann. of Surg.*, vol. xxxviii.) Male, aged 1 month. Kind of crisis, patent at umbilicus. Treatment not stated. Result, *death.* Remarks: Tumor at umbilicus, with hole at summit and escape of fecal matter.

Case 161.—Darnall: (*N. Y. Med. Jour.*, Jan. 12, 1901.) Male, aged 22. Kind of crisis, diverticulitis. The symptoms simulated those of appendicitis. Treatment, *laparotomy. Result.* death. Remarks: The diverticulum was adherent to the umbilicus and [illegible]mal end and perforated.

[illegible] Cited from reprint of paper read before [illegible] 1899.) Male, aged 27. Kind of crisis, [illegible]s a *history* of several previous attacks [illegible] Treatment, laparotomy; resection of [illegible]nastomosis by *Murphy button.* Result, recovery. Remarks: The small intestine was thin at base of diverticulum; the muscular coat had given way. The *anastomosis* was made *of healthy tissue.*

Case 163.—Roth: (Cited by Halstead, *Medical Record*, 1902.) Age, 16 months. Kind *of crisis, diverticulitis.* The symptoms were those of general peritonitis. Treatment not stated. Result, death. Remarks: There was torsion of the *neck* of the diverticulum, resulting in gangrenous diverticulitis with general septic peritonitis.

Case 164.—Swkonski: (Cited by Halstead, *Med. Record*, 1902.) Age, 16 months. Kind of crisis, diverticulitis. The symptoms were those of general peritonitis. Treatment, not stated. Result, death. Remarks: The diverticulum was gangrenous, causing general septic peritonitis.

Case 165.—Squires: (The Journal American Medical Association, Oct. 4, 1902.) Male, aged 23. Kind of crisis, diverticulitis. The symptoms *simulated* appendicitis. Treatment, laparotomy; the diverticulum was excised. Result, recovery. Remarks: The diverticulum was inflamed, *causing* symptoms simulating appendicitis.

Case 166.—Fitch: (Cited by Halstead, *Med. Record*, 1902.) Age *and* sex not stated. Kind of crisis, tuberculous ulceration of the diverticulum. Treatment not stated. Result not stated. Remarks: The diverticulum presented on examination three ulcers.

Case 167.—Dixon: (Cited by Halstead, *Med. Record*, 1902.) Male. Kind of crisis, tuberculous ulceration of the diverticulum. Treatment not stated. Result, death. Remarks: The diverticulum presented on [illegible]tion.

Case 168.—Chauffard: [illegible] *cord*, 1902.) age, 9. Kind of *crisis.* [illegible] during typhoid. The symptoms were those of general peritonitis. Treatment not stated. Result, death. Remarks: The diverticulum presented on examination a tumefied Peyer's patch, but no ulceration or perforation

Case 169.—Halstead: (*Med. Record*, 1902.) Male, aged 26. Kind of cri[illegible]he symptoms were those of general [illegible]otomy: the diverticulum was excise[illegible] The diverticulum was perforated at tip.

Case 170.—Halstead: (*Med. Record*, 1902.) Male, aged 45. Kind of crisis, perforation in typhoid. The symptoms were those of peritonitis. Treatment, laparotomy; the diverticulum was excised. Result, death. Remarks: The diverticulum was adherent to the anterior abdominal wall and was perforated at the tip.

Case 171.—Galton: (Cited by Halstead, *Med. Record*, 1902.) Age, 12. Kind of crisis, perforation in typhoid. The symptoms *were those of peritonitis. Treatment* not stated. Result, death. Remarks: The diverticulum and ileum were perforated.

Case 172.—Boinet and Delanglade: (Cited by Halstead, *Med. Record*, 1902.) Female, aged 35. Kind of crisis, perforation in typhoi[illegible] those of peritonitis. Treatment, laparo[illegible]was excised. Result, death. Remarks[illegible]ound perforated at tip.

Case [illegible] Halstead, *Med. Record*, 1902.) Male, [illegible]verticulitis. The symptoms were those [illegible] *not stated. Result,* death. Remarks: A foreign body was found in the diverticulum as cause of the inflammation.

Case 174.—Demice: (Cited by Halstead, *Med. Record*, 1902.) Age and sex not stated. Kind of crisis, diverticulitis. The symptoms were those of peritonitis. Treatment not stated. Result, death. Remarks: A foreign body was found in the diverticulum *as cause of inflammatory* process.

Case 175.—Best: (Cited by Halstead, *Med Record*, 1902.) Age and sex not stated. Kind of crisis, diverticulitis. The symptoms were those of peritonitis. Treatment not stated. Result, death. Remarks: The diverticulum was filled with cherry stones and perforated.

Case 176.—Houston: (Cited by Halstead, *Med. Record*, 1902.) Age and sex not stated. Kind of cri[illegible]atient had recurring attacks simulating [illegible] not stated. Result, *death.* Remarks. [illegible] filled with fecal concretion.

Case 177.—Galeazzi: (Cited by Halstead, *Med. Record*, 1902.) Age and sex not stated. Kind of crisis, diverticulitis. The symptoms were those of peritonitis. Treatment not stated. Result, death. *Remarks:* The diverticulum was filled with fecal concretion.

Case 178.—Escher: (Cited by Halstead, *Med. Record*, 1902.) Age and sex not stated. Kind of crisis, diverticulitis. The symptoms were those of *peritonitis.* Treatment not stated. Result, death. Remarks: Round worms were found as cause of diverticulitis.

Case 179.—Blanc: (Cited by Halstead, *Med. Record*, 1902.) Age and sex not stated. Kind of crisis, diverticulitis. The symptoms were those of peritonitis. Treatment not stated. Result, death. Remarks: A fish bone was cause of the diverticulitis.

Case 180.—W. Kramer: (The Journal of the American Medical Association. 1898.) Age and sex not stated. Kind of crisis, diverticulitis. The symptoms were those of peritonitis. Treatment, *laparotomy*; resection of diverticulum between ligatures. Result, not stated. Remarks: A fruit seed was cause of the *diverticulitis*; diverticulum was perforated.

Case 181.—Cramer: (Cited by Halstead, *Med. Record*, 1902.) Age and sex *not stated.* Kind of crisis, diverticulitis. The symptoms were those of peritonitis. Treatment not stated. Result not stated. Remarks: *The diverticulum* was ruptured as result of kick by horse, causing suppurative peritonitis.

Case 182.—C. C. Smith: (*Ann. of Surg.*, November, 1905.) Age, 10. Kind of crisis, diverticulitis. The symptoms simulated appendicitis. Treatment, laparotomy; the diverticulum was *excised* between ligatures. Result, recovery. Remarks: The diverticulum was inflamed and adherent to the omentum.

Case 183.—*Nicolson: (Cited* by Smith, *Ann.* of *Surg.*, November, 1905.) Age and sex not stated. Kind *of* crisis, diverticulum gangrenous with adhesions *causing obstruction.* Treatment, laparotomy. Result, death. Remarks: The diverticulum was gangrenous and adherent to umbilicus, acting *as band*, causing obstruction.

Case 184.—Bernays: (Personal communication.) Age and sex *not stated.* Kind of crisis, diverticulitis. The symptoms were those simulating appendicitis. Treatment, laparotomy; the diverticulum was *excised.* Result, recovery. Remarks: The diverticulum was inflamed *and* gangrenous.

DISCUSSION.

Dr. R. Winslow, Baltimore, mentioned two cases. In one he encountered a Meckel's diverticulum in a gangrenous hernia, which resulted fatally. The other patient, a woman, was recently taken to him with a lump in her right side. It was somewhat movable, and operation was performed under the impression that it was probably an appendicitis. Dr. Winslow found a pus tube with a large ovary, chronic appendicitis and Meckel's diverticulum, all surrounded by omentum. He removed the diverticulum and the appendix and the patient recovered.

Dr. W. Jepson, Sioux City, Iowa, said that it is certainly somewhat remarkable that there exists such a paucity of reported cases wherein this remnant of embryologic life has led to morbid processes demanding operative interference; especially is this so when it is considered that postmortem findings reveal the fact that from one to two of every hundred individuals are possessed of a Meckel's diverticulum. He is of the belief that serious intra-abdominal disturbances occasioned by this structure are observed by surgeons more frequently than is borne out by reported cases. Three cases coming to operation have been observed by him. One was the case of a child 16 months old, suffering from intussusception. When the bowel was exposed it was found that a Meckel's diverticulum was primarily intussuscepted, and this in turn caused an intussusception of the ileum. The intussusceptions of the ileum and of Meckel's diverticulum were readily reduced. Owing to the child's grave condition, Dr. Jepson did not feel warranted in removing the diverticulum as he otherwise would have done. No difficulty has been experienced by the child since that time, now nearly three years ago. The second case occurred in a man 37 years of age who possessed a diverticulum which was dilated, being about the size of an orange. It contained fourteen concretions, each being about the size of a hickory nut, besides a great number of other food products, such as grape seeds, etc. The contents of the diverticulum produced such traction on the bowel that it led to an angulation with consequent intestinal obstruction, which in turn disturbed the circulation of the diverticulum so that it became gangrenous. The third case observed was one in which the diverticulum became strangulated in the sac of a right inguinal hernia.

Dr. Miles Porter stated that Dr. Cheyne says that in cases of intussusception of Meckel's diverticulum the mucous membrane alone is turned in, but in the three cases which he has examined it included all the coats.

EXSTROPHY OF THE BLADDER SUCCESSFULLY TREATED BY PETER'S METHOD.*

HARRY M. SHERMAN, M.D.
SAN FRANCISCO.

I am submitting the report of a single case, because it illustrates well an exceedingly easy method of meeting difficult conditions and controlling them almost entirely, so far as theoretical considerations go, and quite entirely so far as this particular case is concerned.

It is hardly necessary to repeat that the ordinary plastic operations which contemplated the creation of a bladder, in cases of exstrophy of that organ, did not include the creation of a sphincter vesicæ; and yet a bladder with no sphincter is really no bladder, but is only a wider part of the urinary tract. After the most brilliant success in an operation of this type the patient has to wear a urinal, his real bladder, hanging down by his leg.

The utilization of the colon or rectum as a receptacle for the urine, an artificial reversion to the avian type, was resorted to, in order to make the sphincter ani do the work of the absent sphincter vesicæ. The genuine brilliancy of the idea, which may be credited to John Simon[1] in 1805 could not at the time of its inception be rewarded by a practical result, for the sepsis that naturally followed any such operation at that period killed the patient. The same sepsis has stood steadily in the way of the method during all the intervening years and probably will always stand there, but in some details it has been circumvented, more especially the septic peritonitis, by the simple plan of avoiding the peritoneum, while the septic nephritis, unless statistics wholly mislead, has been so long postponed as to give rise to the hope that it may never occur.

The operation accomplishing this, described by the originator, George A. Peters,[1] of Toronto, avoids opening the peritoneum by confining the work to the space in the abdomen and pelvis, below the vesicorectal limits of the peritoneum, in both males and females, and so narrows the possibility of septic danger to that inherent in all operation work and avoidable in almost all, and that, too, due to the ascending infection of the ureters and kidneys.

The operation dissects out the ureters individually, keeping a small circular patch of bladder wall around the vesical orifice of each. The rest of the bladder wall is ablated. Each ureter, with its button of bladder wall, is then drawn through a small slit in the rectal wall of its own side and left hanging from 1 cm. to 1.5 cm. into the rectal lumen.

This very general statement covers the fundamental idea of the operation, for the peritoneum has not been opened; but there are certain details of technic which seem debatable and I have sufficient assurance to wish to discuss them in the light of my one case.

The idea on which the operation of Maydl was based, namely, that there was a sphincteric action in the muscular layer of the bladder wall around the openings of the ureters, and that this required the conservation not only of this muscular fiber which surrounded each ureteral orifice, but also of those that surrounded both of them together, has to be abandoned; and with it may be given over the necessity for transplanting the whole of the trigone of the bladder into the colon or rectum, and making it practically a part of their wall. It is only necessary, therefore, to conserve such part of the bladder wall as surrounds each ureteral opening individually, and even this not with the idea that it contributes a sphincteric control of the opening, but merely with the idea that the wound of the mucous membrane is made at a reasonable distance from the mouth of the ureter and that the ureteral mucosa itself is left absolutely intact.

In the earlier operations which Peters himself did, he passed into each ureter a small catheter and fastened it there. Its presence in the ureter served as a guide which prevented the wounding of the ureter during the operation and afterward served as a means to conduct the urine out of the rectum during the first thirty-six to forty-eight hours following the operation. In one of Peters' patients an ascending infection occurred and the patient died, and Peters thought that the infection possibly was due to the fact that he had left the catheter in the ureter after the transplantation of the ureter into the rectum. This made me desire to avoid the use of the catheter at all, and as I began my operation I attempted to dissect out the ureter without the assistance of the catheter as a guide. I did this quite as much because of the infected state of the exposed vesical mucosa and the fear that in passing a catheter into the ureter I should carry up with it a certain amount of the infection. I found, however, that the dissection in the abnormal anatomic relations of the parts in these exstrophied cases was difficult, and I fortunately put into each ureter a small ureteral catheter to act as a guide, for had I not done so I should quite certainly have cut off the right ureter from ignorance of its anatomic location. In this one case of mine I found that the ureters approached the bladder from either side of the abdomen and passed transversely from the periphery of the exstrophied bladder toward their openings.

I believe that it will be wise for anyone who is undertaking this particular operation to put into each ureter before he dissects it out, a ureteral catheter. After the dissection has been completed, the catheter should be removed. It is no longer of service.

I departed from the Peters technic in that I did not retain the catheter in the ureter after the latter had been transplanted into the bladder. Instead of that I let the ureter begin to discharge urine into the rectum from the first and merely saw that its exit was arranged for by a tube in the anus. In the operation, as Peters has described it, dilatation of the sphincter ani was practiced so as to permit free exit for the urine. Of course, stretching the sphincter is a simple and common matter, and very rarely results in paralysis. It is quite possible, however, for a man to stretch the sphincter of a child more than he thinks he is doing, and as the end for which the stretching is done can be equally well attained by fastening a little rubber tube in the anus, it seems wise to me not to stretch this sphincter; and the plan has worked well, at least in this one case of mine. I can not well conceive how a man could be more mortified than to find, after he had made a successful transplantation of the ureters into the rectum, that he had no sphincter ani, and that all that he had accomplished by his operation had been to change the point of incontinence from the hypogastrium to the anal region.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] Peters, Brit. Med. Jour. 22, June 1901.

In the operations which Peters has described, he packed the opening in the hypogastrium and let it gradually cicatrize. There seems to me to be a fairly good reason for this, for if there is any leakage from the rectum by the side of the ureter through the little opening which is made for the introduction of the ureter, the packing would act as a drain to the surface and so prevent a local and possibly general infection. Peters has not closed the openings in the rectal wall in any way. In my one operation I put in a single catgut stitch which brought the opening down to a size just sufficient to contain a ureter, and in the stitch I caught up a little of the periureteral areolar tissue which had been kept with the ureter to carry its blood vessels. This precluded the probability of any leakage from the rectum, and I should think it would be quite possible in some of these cases immediately to suture the recti together and so close, at once, the abdominal wall. In my own case I could not do this, for the child was very feeble and was already on the verge of shock when I had completed the transplantation, so that I followed Peters' plan and merely packed the abdominal wound. Later, after the general condition of the child had improved, it was a simple matter to go back and make a firm suture of this abdominal wound, it having in the meantime practically filled up with granulation tissue and nearly cicatrized over. In doing this I was surprised to find how easy it was, in this particular case, to draw the recti together, even though there was no os pubis on either side and no symphysis.

In the ablation of the vesical mucosa I was particularly careful to leave untouched the prostatic urethra which lay as an open saucer-shaped space in its usual location, and in it could be plainly seen the openings of the seminal ducts. From it extended, as a gutter, the open urethra. At a secondary operation I closed in the urethra from the meatus to the prostatic portion by the Duplay method, but I failed at first, to get union over the prostatic sinus. This has been accomplished, however, at later operations. This child, therefore, has a genital canal, normal up to his prostatic urethra, and from that point on to the meatus completed by an artificial closure of the urethra which should, in time, give him the opportunity of doing his duty toward the propagation of the species.

Reverting to the history of the convalescence of this child, it is only necessary to say that from the beginning his rectum acted perfectly well as a bladder, and would retain his urine from one to two hours. Later the period was increased to three or four hours, being only a little longer in the daytime than in the night. An examination of the urine which was voided, usually independently of any feces, though sometimes there were small fecal flecks in it, showed it to be acid, to have a cloud of albumin, and to have no sugar, but there were present triple phosphates, amorphous urates and bacteria. During the period of the child's residence in the hospital, he was given small doses of hexamethylenamin with the idea of preventing an ascending infection. Whether or not this was of use I can not say, but no ascending infection occurred up to the time of his leaving the hospital, and reports from his home state that he is in excellent health. At the time the child left the hospital, he was different from the ordinary child only in having a scar in the middle line of the lower part of his abdomen, representing a place which had formerly been occupied by the bladder. His penis was somewhat short, and a scar ran along its dorsum where satisfactory union of the integument had not occurred. His urethra extended from its proper opening on the tip of the glans backward to the prostatic portion. To urinate he had to sit down as if he was going to have a stool, and his urine came from his rectum. A finger in the rectum could feel, on either side, just above the internal sphincter, the little projections of the ureters which, each with its button of vesical mucosa, hung close to the rectal wall. It may not be an impossibility for him to go through life without any but the most intimate of friends knowing his differences from them.

Peters has reported four cases in the literature, and in March, 1905, he wrote me that he had operated in his fifth case. Katz of Braila, Roumania, reported, in 1903, nine operations transplanting the ureters individually into the rectum, and these include Peters' four cases. Of the other five operations, only one, that of Pye Smith, was by Peters' technic. The other operators, Pozzo, Capello and Colzi (two cases) transplanted the two ureters apparently by one opening on the anterior wall of the rectum; and each patient had a urinary fistula. Of these nine patients, only two have died of ascending infection: Peters' patient and Colzi's first patient, the former on the fourth day and the latter after seven months. Peters' fifth case case and my one bring the total up to eleven cases.

Peters' first operation was done in 1901, and the patient has now lived four years with his rectum doing duty as his bladder. It is not false reasoning, I maintain, to argue that as this boy has gone four years he may go eight years, and if he goes eight he may go sixteen; many a justifiable surgical procedure has a less secure foundation. The operative technic is simple and easily performed, and the operation should not prove a difficult task in the hands of anyone who has ordinary surgical ability. The condition for which it is proposed is one in the extreme, and I can not but think that a great deal has been given to us in this method. The Maydl operation had a mortality of about 33 per cent., the deaths being due to chloroform, hemorrhage, hydronephrosis, peritonitis and pyelitis. This particular operation has not been done often enough to warrant the calculation of percentages, but I do not see why the operation itself should entail any mortality, except, perhaps, in very weak and puny children. Septic peritonitis, which can not help being a fatal factor in the Maydl operation, whether the transplantation of the trigone be made into the rectum or into the colon, is here eliminated entirely. The only unavoidable danger is in the ascending infection, and there seems good reason to believe that this may be indefinitely postponed.

DISCUSSION.

Dr. E. A. Wells, Hartford, Conn., stated that he assisted Dr. Hartley[1] of New York in two operations similar to those of Dr. Sherman. The first patient was not operated on for exstrophy, but for chronic tuberculous cystitis; however, the principles of the operation are the same. Both patients were 18; one a girl, the other a boy. I say a boy, because his general non-development gave him that appearance. Dr. Hartley dissected out the trigone of the bladder in these cases, and freely opening the peritoneal cavity, inserted this into the sigmoid flexure of the great intestine. The abdominal wound was closed immediately. Both these patients did well. At last reports both could hold their urine a normal length of time and could void it at will and separately from the feces. The girl is married and has had a child. The boy has had several previous operations for his exstrophy, epispadias, etc., to no avail. Dr. Hartley did not use a ureteral catheter. If this is used, one should be very careful to avoid unnecessary traumatism about the ureteral orifice, as on the integrity of this bit of tissue depends in large measure the success of the operation. It is undoubtedly better to do the operation as Dr. Sherman suggests, namely, without opening the peritoneal cavity.

---

[1] Med. News, Aug. 29, 1903.

Dr. L. L. McArthur, Chicago, said that some experiments have been made by Dr. Peterson of Ann Arbor and Dr. Martin of Chicago, with a method of implanting the ureter into the rectal wall so as to militate against the backward regurgitation. They have been able to accomplish this by making an oblique implantation of the ureter into the rectum projecting a portion well into the lumen of the rectum, as done by Dr. Sherman, but in addition burying the portion outside of the rectum by infolding the rectal wall around the urethral wall for an inch. By these means they claim that as fecal masses pass they tend to milk, rather than to overcrowd infection into the ureter, thus materially lessening the danger of an ascending pyelitis. They seem to have added something to the technic.

Dr. H. M. Sherman said that he thinks the operation referred to by Dr. Wells was the regular Maydl operation, and he does not think Dr. Hartley varied its technic. Dr. Dudley Tait of San Francisco and Dr. Sherman spent every Sunday morning for many Sundays trying to do the Maydl operation on dogs. They killed many dogs doing it, and every one died of peritonitis. This is the experience of everyone who has tried to transplant both ureters in dogs, and this difficulty impressed itself on them. The dog's bladder is entirely intraperitoneal, and it is impossible to open it without opening the peritoneum. Peter's operation consists in dissecting out each ureter individually with a button of vesical mucosa, and passing dressing forceps into the rectum and then through its wall with which to grasp the button of vesical mucosa. The transplantation of the ureters into the rectum is thus exceedingly simple and easy, and takes only a few minutes. It is all an extraperitoneal manipulation. The obliquity of the puncture in the rectal wall can not make much difference, for even if it was made oblique it would probably soon become direct. No account is taken of the fact that the feces pass over the opening of the ureter, as they seem to have done no harm. Ascending infection has not occurred in any patient except the one in whom Peters kept the catheter too long in the ureter. One point is important: one must avoid wounding the vesicle or ureteral mucosa. The difficult matter in Dr. Sherman's case was closing the urethra. It is a mistake to approach this operation with the expectation of finding this plastic work on the epispadias easy because of the fact that no urinary function is going on in the urethra. Compared with this the trasplantation of the ureter into the rectum is very simple.

DRUGS AND THE DIAZO REACTION.*

WILLIAM W. GOLDEN, M.D.

ELKINS, W. VA.

It is not my purpose to enter here into a discussion of the extent of the value of the diazo reaction in clinical work. I take it for granted that physicians are all making use of the test for this reaction, and that like myself they have found it of much help, particularly in the diagnosis of typhoid fever.

During the past year, a statement from an Italian source appeared in the medical press of this country to the effect that certain drugs when ingested will cause the urine to react positively to the usual diazo test. An editorial in a leading medical journal seemed to take this statement for granted. This has induced me to institute some observations on this subject in the wards of the Davis Memorial Hospital, the details and results of which I herewith submit.

Observation 1.—A man aged 40, recovering from a compound fracture of the femur. All functions were normal; urine normal. To simulate the dietetic conditions of typhoid fever, he was placed, during the period of observation, on an exclusive milk diet preceded by an effective dose of castor oil. Three grains of thymol were administered every three hours for forty-eight hours, and the urine tested for the diazo reaction at the middle and at the end of this period. Result negative.

Observation 2.—A man, aged 19, recovering from a fracture of both femurs. General diet. All functions normal; urine normal. Five grains of salol were administered every four hours for a week and the urine was tested for the diazo reaction every twenty-four hours. Result negative.

Observation 3.—Patient of the last observation. All functions were normal; urine normal. After the salol was stopped, he was placed on guaiacol carbonate gr. 3 every three hours for forty-eight hours. Urine was tested for the diazo reaction at the end and at the middle of that period. Result negative.

Observation 4.—A woman, aged 39, recovering from an oöphorectomy. There was some intestinal fermentation, otherwise normal; urine normal. General diet. She was given 5 grains of sodium sulphocarbolate every three hours for three weeks. Urine was tested repeatedly for diazo reaction during that period. Result negative.

Observation 5.—A man, aged 55, recovering from a simple fracture of the femur. All functions were normal; urine normal. Exclusive milk diet. Five grains of salol were given every four hours for 48 hours. Urine was tested for the diazo reaction at the end and at the middle of that period. Result negative. The dose was then increased to 7 grains and continued for another 48 hours. At the end of this period the urine showed the characteristic dark color. Diazo reaction was absent.

Observation 6.—A woman, aged 39, recovering from an operation for hemorrhoids. All functions were normal; urine normal. Exclusive milk diet. Five grains of salol at intervals for forty-eight hours and the same drug in doses of 7 grains for 48 hours longer. Urine was tested for the diazo reaction at intervals of twenty-four hours. Result negative.

Observation 7.—A man, aged 35, recovering from a contusion of the thighs. All functions were normal; urine normal. General diet. Three grains of thymol were given every three hours for seventy-two hours. Urine was tested at the end of each twenty-four hours. Result negative.

It would seem, therefore, that while the observations are not large in number, as far as they go they most emphatically disprove the assertion that salol, thymol, sodium, sodium sulphocarbolate and guaiacol carbonate have the power of producing the diazo reaction in the urine of persons taking these drugs.

While working on this subject it occurred to me that it might prove of interest to the general practitioner to learn whether this reaction, when present in the urine, would continue to be present after the urine stood for some time with or without the addition of preservatives, as it so often happens that a physician is unable to test it for some time after it is voided. The following observations were made:

Observation 1.—Sixty c.c. of typhoid urine with a marked diazo reaction was allowed to stand in an open conical glass for 48 hours in a temperature of about 70 degrees F. Marked decomposition was present at the end of that time. After filtrating the urine the diazo reaction was found present and as intensely marked as when it was fresh.

---

* Read before the West Virginia State Medical Association, 1905, at Wheeling, W. Va.

Observation 2.—To 60 c.c. of the same urine 2 c.c. of chloroform was added and allowed to stand for one week. The reaction was found unimpaired at the end of that period.

THE FAT OF TOP MILKS.

JOSEPH W. ENGLAND, Ph.G.
AND
CHARLES H. LA WALL, Ph.G.
PHILADELPHIA.

The use of top milks in infant feeding is rapidly increasing, and we have thought it advisable to examine the typical milks of the Philadelphia milk market for their percentages of fat, particularly the milk sold with a certificate of quality issued under the authorization of the Philadelphia Pediatric Society.

The certified milks of Philadelphia are, Dr. J. P. Crozer Griffith informs us, four in number, as follows: The Willow Brook Farm, the Haddon Farm, the Wawa Dairy, and the Bryn Clovis Farm. Since this information was received, we have learned that the sale of certified milk by the Bryn Clovis Farm has been discontinued.

We have examined, also, the Walker-Gordon guaranteed milk, in one pint and one quart bottles, and the milk regularly sold by four representative milk dealers of this city.

The certified milks, we are told, are from milkings made about 4 p. m., bottled on the farm, and delivered to the consumer the following morning. They are then about 16 hours old. The regular milks we examined were sent in bulk to the city, and bottled on the evening before delivery, and were about 16 hours old when examined.

Of the three certified milks of Philadelphia, two are sold only in one-pint bottles, and the third is sold in both one-pint and one-quart bottles. This fact is important, because the formulas for milk modifications with top milks are all based on the use of top milks taken from one-quart bottles, and not from one-pint bottles; and our experiments show radical differences in the fat percentages of top milks as taken from each. The sizes of the bottles were:

	Height. Inches.	Outside diameter at base. Inches.	Inside diameter of neck. Inches.
Pints (certified)	8⅛	2½	1¼
Pints (certified)	8⅛	2½	1¼
Pints (certified)	8	2¾	1½
Pints (guaranteed)	7	2⅞	1⅜
Quarts (certified)	9¼	3¾	1⅜
Quarts (guaranteed)	8¾	3¾	1⅜
Quarts (regular)	8⅛	3¾	1¼
Quarts (regular)	9	3¾	1½
Quarts (regular)	9¾	3¾	1¼
Quarts (regular)	8¾	3½	1⅝

The differences in sizes will be noted. While small, in some instances, the size and shape of containers exert an important influence in creaming, or the production of the top milks, more so than the difference would apparently indicate. The height of the layer of cream was from 2½ to 4 inches. As a rule, the less high the creamy layer the denser and richer in fat.

While the amount of cream is governed by the amount of fat in the milk, the shape and size of the container and the length of time the milk has stood are factors of equal or greater importance.

Creaming, that is gravity-creaming, is the separation or raising of the fat globules to the surface of milk. It is mechanical in action. The more narrow and cylindrical the container the readier the creaming and the more dense the upper layer; the broader the container the less ready the creaming and the less dense the upper layer. This is shown by the differences in the creams obtained from an open pan and from a tall cylindrical bottle.

The fat globules are suspended in the milk. It is generally believed that each globule is surrounded by a thin nitrogenous membrane, protoplasmic in origin, which becomes ruptured on churning. This theory is by no means universally held to-day. Babcock and many others believe that milk is simply a natural emulsion.

The length of time a milk has stood before the top layers are removed is a most important factor. We found that a one-half ounce of top milk, 16 hours old, assayed 17.6 per cent. fat, and 24 hours later another half-ounce of top milk from the same bottle assayed 26.4 per cent. (It should have assayed much less, as the richer layer had previously been removed). Similarly, a one-ounce sample was increased from 15.2 per cent. to 16.5 per cent, another one-half ounce sample from 19.8 per cent. to 32.4 per cent., and another one-ounce sample from 18.4 per cent. to 26.4 per cent.

	....	....	....	....	4.60	3.60	4.40	3.75	5.20	5.40	....	....	....

* The high percentages in these cases are probably due to the cylindrical shape of the bottle and the small inside diameter of the neck.

† The low percentage in this case is undoubtedly due to the shape of the bottle and probably also to the shorter time of creaming.

In our determinations of fat, the Leffmann and Beam method,[1] devised in 1889, was used. This method gives rapid and exceedingly accurate results.

In the table given, references are made to the standards of Winters,[2] on which many of the formulas in general use are based.

Examination of these results reveals a number of interesting facts. The percentage of fat in whole milk varies greatly. Leach[3] reports such variations to be 180 per cent.

1. The richer the upper layers of top milks in fat the poorer the lower layers.

---

[1] Leffmann and Beam's "Food Analysis," 1905, p. 203.

[2] "Feeding in Early Infancy; Home Modification of Milk," by Joseph E. Winters, M.D., Professor of Diseases of Children, Cornell University Medical College, Medical Record, March 7, 1903, p. 366.

[3] Food Analysis, 1904, p. 91.

2. The differences in the fat percentages of top milks in pint bottles and quart bottles are marked, especially in the lower layers. The variations in extreme limits from the minimum to the maximum were from 60 to 170 per cent. The maximum variation of the whole milks examined was nearly 50 per cent.

3. The quart bottles of the Philadelphia milks follow the Winters' standards for the upper one-half ounce, one ounce, two ounce and four ounce very closely. Above that the differences are wide.

4. The pint bottles of certified milks follow Winters' standards nearly for the upper one ounce and two ounce, but differ radically in all the rest. *The one-pint bottles of milk should never be used instead of one-quart bottles for obtaining top milks for infant feeding, as the differences in fat percentage are too great.*

In the Winters formulas for the modification of milk for infants of less than 1 month of age, one-half ounce of top milk from each of two quart bottles of milk is used in 11.5 ounces of food, and the fat percentages run about from 1.75 to 2.5 of fat, instead of 2 per cent. (Winters standard); where the upper half-ounce from each of three one-quart bottles is used in 14 ounces of food, the fat percentages are from 2 per cent. to 3 per cent., instead of 2.5 per cent. (Winters standard); where the upper 2¼-ounce from one-quart bottle are used in 14½ ounces of food, the fat percentages are practically 2.75 to 4 per cent., instead of 3 per cent. (Winters standard): where the upper six ounces from one-quart bottles are used in 28 ounces of food, the range is from 2.5 to 4 per cent., instead of 3.5 per cent. (Winters standard).

When larger quantities of top milk are used, say 8 ounces from a quart bottle in 32 ounces of food, the fat percentage will be from 2.2 to 4.1 per cent:; when 12 ounces are used in 32 ounces of food, the fat percentage will be from 2.85 to 4.35 per cent.; when 16 ounces are used in 32 ounces of food, the fat percentages will be from 3.05 to 4.2 per cent.

From this data it will be seen, at least so far as the Philadelphia milks are concerned, that *the use of diluted top milks from one-quart bottles for the very young is not attended with such serious differences of fat percentage as the differences in the fat percentages of the undiluted top milks might imply or as to justify the disuse of top milks.* At the same time the fact must be borne in mind that in cow's milk, probably, as in human milk, the ratio of fat to proteid is the highest at birth, and gradually decreases until the period of dentition is reached; for this reason the percentages of fat in cow's milk are most variable. It is well known that the most uniform milk is obtained by mixing the milk of a herd of cows rather than using the milk of a single cow. The same rule holds true with reference to the other constituents *of milk, though not to the same extent.*

The possibility of considerable variation in the percentages of sugar, fat and proteids in cow's milk, and consequently in top milks, should never be forgotten in the percentage feeding of infants. It is impossible to get absolutely exact percentages without analyzing each and every lot of milk used, and this is, of course, impracticable. As some one has wittily said: "The difficulty with those who seek scientifically exact percentage modifications of milk is that, with all their rules and tables, they fail to consider the party most deeply interested; *that is, the cow.*" *In obedience to physiologic* laws, the cow makes her milk to suit the needs of her calf, and these needs are governed by the breed, age and individuality of the calf, and doubtless other factors.

Apparently the best results in top milk infant feeding are to be had by approximating percentages; that is, by having them reasonably accurate, and then adjusting, if necessary, the relative proportions of top milk and diluents to suit the individuality of the child.

415 North Thirty-third Street.

THE FREEZING POINTS OF BLOOD AND OF URINE IN PNEUMONIA.

WITH DESCRIPTION OF A NEW METHOD.*

F. E. SCHMIDT, M.S., M.D.
CHICAGO.

The object of this study[1] was to ascertain the freezing points of the blood and of the urine in *pneumonia;* to determine the relation of such findings to the course of the disease; and to note any possible bearing the same may give with regard to the prognosis of this disease. Before discussing the methods employed and the observations made in the cases studied, it will be well to mention briefly the work of other investigators who have used cryoscopy in their researches.

A BRIEF REVIEW OF CRYOSCOPY AS USED IN MEDICINE.

As early as 1871, De Coppet[2] showed that the freezing point of water is lowered a definite amount by the addition of a molecule or proportionate quantity by weight of any soluble substance. Little was done, however, following this finding until Raoult[3] studied the freezing points of various solutions and derived his important laws. Van t'Hoff[4] later proved that equal volumes of isotonic solutions contained the same number of molecules or fragments of molecules, and have the same freezing point. Then D'Arrhenius[5] modified these laws to comply with his own *laws of solutions.* No one, however, regarded cryoscopy from a medical standpoint until *Koranyi,*[6] *regarded* by all as the father of cryoscopy, published the wonderful results of his studies on the osmotic pressure of the various fluids of the human body. Since the appearance of his articles, many investigators have worked on the subject, adding little by little to his data. Roth[7] compared the electrical conductivity with the freezing point of urine, agreeing with the findings of Koranyi.[6] Lindemann[8] studied the concentration of the urine and of the blood in renal diseases, and their relation to uremia. Claude and Balthazard[9] followed the above with experiments on the freezing point of urine in various diseases. Senator,[10] Kummel,[11] and Hamburger[12] verified the works of previous investigators. Waldvogel[13] studied the freezing points of the blood and of the urine in typhoid fever, but his results were found inconstant by Rumpel.[14] According to Ogston[15] the findings in hepatic diseases are similar to those found by Koranyi in disturbances of the kidneys. Landau[16] compared the freezing points of venous and arterial bloods, finding that stagnant and venous blood have a freezing point one or two hundredths of a degree centigrade lower than arterial blood. Sollmann[17] wrote extensively on the concentration of the urine as an aid to diagnosis. Tinker[18] studied cryoscopy as an index to renal insufficiency in surgical diseases of the kidney. The latest important use of the cryoscope was brought out by Lobenstein[19] in his work on the molecular concentration of blood and of urine in pregnancy, puerperium and eclampsia.

PREVIOUS CRYOSCOPIC FINDINGS IN PNEUMONIA.

Contrasted with the large amount of work done with the cryoscope on renal diseases, very little has been attempted in pneumonia. Koranyi[9] made the most important contributions. His results are briefly as will follow. He determined that the freezing point of the blood is higher, i. e., above 0.56 degrees C. in anemias and those fevers which do not interfere with the respiration. Chlorosis, tuberculosis, and the various cachexias are included under this head. Further, the freezing point of the blood is lower than 0.56 degrees C. in all diseases which are accompanied by deficient respiration or kidney function, or both. The essential difference between the quality of the blood and of the urine in cases with lessened aëration and that in renal insufficiency, is that in the former the low freezing points are raised by the administration of acids. Where both kidney and lung functions are deficient, as in heart cases, the great concentration of the blood can be decreased by the exhibition of acids, but can not be brought to normal. The freezing point of the blood may be essential in diagnosis between typhoid and pneumonia, for, if the freezing point is lower than 0.56 degrees C., the case is very likely pneumonia. On the other hand, should it be higher than 0.56 degrees C., typhoid fever is more probable. In pneumonia the blood change can be corrected by administration of acids. In regard to the urine, the freezing point in anemias is above 1.4 degrees C. With recovery the freezing point is lower. In increased kidney circulation the increase in salt excretion is greater than that of other molecules; therefore, the quotient in such cases of the freezing point of urine divided by NaCl per cent. secreted is low. In slowed circulation the salt secretion is decreased more than the other molecules. Hence the freezing point of urine divided by NaCl per cent. rises in value. If, in fevers, the freezing point of urine divided by NaCl per cent. is lower than 1.7, malaria is indicated. If this quotient is greater than 1.7, malaria is contraindicated.

Lindemann[8] found that the concentration of the blood increases if the excessive substances are not eliminated from the blood, even though there is no absorption by the tissues of the body. Sollmann[17] notes that the height of a fever has no special influence on the urine, and that the same results are found when a healthy person is on a milk diet. He found that in heart diseases, pneumonia, ascites, etc., with cardiac weakening, the freezing point of the urine is lowered. Claude and Balthazard[9] found that the volume of urine excreted in pneumonia is decreased during the disease up to the crisis, when it rapidly increases. The freezing point, however, is markedly lower, due to the increased concentration of the urine. The lowering is due, however, to the great increase in elaborated molecules excreted, and not to the chlorids, the latter having diminished. Three days after the defervescence of the fever, the reverse conditions are present, that is, the amount of urine is increased, the freezing point becomes normal, while the chlorid secretion increases at the expense of the non-chlorid molecules.

METHODS EMPLOYED.

A. *To Determine the Freezing Point of Urine.*—This is done usually by a Beckmann apparatus or one of its modifications. A thermometer, capable of being read to 0.01 degrees C. is supported by a rubber stopper in a large test tube, A, and should be at least 5 millimeters distant from the walls of the test tube. The thermometer should be graduated from 1 degree centigrade above, to 4 or 5 degrees below the freezing point. A stirring rod, preferably one of platinum, should pass through the cork holding the thermometer, and in a spiral around the latter. This test tube should be fitted by means of a rubber stopper into a larger test tube, B, which in turn is supported in a jar containing the freezing mixture, the temperature of which should be at least —5 degrees C. An air space is thus left between the freezing mixture and the solution to be frozen, insuring gradual cooling. The thermometer should be tested daily in a 1 per cent. solution of sodium chlorid, the freezing point of which is known.

To determine the freezing point of a solution, 10 cubic centimeters of it are placed into test tube A, and the apparatus set up as outlined above. The fluid to be tested should always be cooled down near the freezing point before beginning the experiment, and constant stirring is necessary. The mercury sinks at first considerably below the freezing point, and then, as freezing occurs, heat is given off and the mercury rises again to the solidifying temperature, which result is tabulated when the column of mercury has remained stationary some thirty seconds. It is safest to remove tube A after the first result, allowing the ice of the tested liquid to melt, and then retest. These two results should agree to 0.004 degrees C., although .02 degrees C. is sufficiently accurate, ordinarily.

The method described above is simple, easy, and rapid. The determination does not take more than ten minutes after the apparatus has been set up and standardized. The necessity of testing the thermometer daily is rather annoying. More simple instruments with fixed freezing points have been suggested for this purpose. These are not quite as delicate, but are sufficiently accurate for clinical work on urine.

When the urine contains considerable urates these are thrown out of solution by the cooling, so that the observed concentration is lessened by the amount of these precipitated salts. This quantity is, however, so small that it may be safely neglected; in fact, it is not easily possible to make any correction. It would not do to dilute the urine, since this alters the dissociation.

B. *To Determine the Freezing Point of Blood.*—Having decided that it would be impracticable to get 10 cubic centimeters of blood daily from pneumonia patients, the method of Koeppe[20] for determining the osmotic pressure of the blood by means of the hematocrit was used as modified by Richard Sommer[21] to calculate the freezing point of the blood. His explanation of the method follows:

[17] Sollmann: Amer. Medicine, vol. iv, No. 17, 1902, p. 656.

[18] Tinker: Johns Hopkins Hosp. Bulletin, vol. xiv, No. 147, 1903, p. 162.

[19] Lobenstein: Am. Med., vol. viii, No. 16, p. 685.

General Principles: The determination is made according to the laws of Van t'Hoff.

(*a*) The osmotic pressure of the blood corpuscles is the same as that of the plasma, because a plasmolysis or a plasmoptysis takes place.

(*b*) If the blood corpuscles are brought into solutions of different osmotic pressures they change their volume in a definite manner until the osmotic pressure of the blood corpuscles is the same as the solution in which they are placed.

(*c*) The osmotic pressure is proportional to the concentration of the solution.

(*d*) The lowering of the freezing point of a solution is proportional to the concentration of the solution (law of Blagden).

(*e*) The lowering of the freezing point of a solution is proportional to the osmotic pressure of the same (law of Van t'Hoff).

(*f*) A solution which holds in solution a grammolecule to the liter has an osmotic pressure of twenty-two and thirty-seven hundredths approximately (Van t'Hoff).

Apparatus: (1) Graduated hematocrit tubes which differ from the ordinary in that the tube is enlarged proximally into a little bulb. The tube is graduated into hundredths. The readings are taken with a hand lens, with which one can with accuracy estimate one-quarter of one of the graduations. The lumen of the tube is so small that one drop of blood is enough to fill this tube several times.

(2) Electric centrifuge, which must revolve very evenly and rapidly.

(3) An instrument to get blood from, preferably, the ear. The regular precautions are taken as in all blood work.

(4) A number of clean watch glasses to receive standard solutions. Care must be taken not to allow solutions to come in contact with other soluble substances.

(5) A hand lens to read the graduation on the tube.

(6) A Beckmann freezing apparatus for determining the freezing points of the standard solutions.

(7) Sterile cedar oil is used in order to prevent the blood from being mixed with foreign substances which may hasten coagulation of the blood.

(8) Standard solutions of certain chemicals which do not act on the blood corpuscles when in solution. The experimenter decides the one he shall use. The substances that are employed commonly are cane sugar, sodium chlorid, potassium bichromate and potassium oxalate. Eijkmann uses sodium chlorid; Koeppe, cane sugar, and Sommers, potassium bichromate. The cane sugar method is the best for the accurate worker, but the solutions are hard to keep. It is understood that the materials must be chemically pure. Each one of these solutions has advantages and disadvantages. For potassium bichromate it can be said that it does not coagulate the blood nor destroy the corpuscles. Since the coagulation of the blood is harmful to the experiment. it is best for the beginner to use this salt. The solutions last long when scaled. A weak solution containing twenty grams to the liter and a strong solution with fifty grams to the liter are used. The freezing point of each is obtained and marked on the flask.

Procedure (according to Koeppe):[20] In a clean hematocrit tube a little cedar oil and immediately after a little blood are aspirated. The tube is immediately closed without reading the graduation and centrifuged. When the centrifuging is completed, there will be three definite lines to read off, namely: Blood corpuscles as the lowest part, plasma as a middle part, and the cedar oil on top. The quantity of blood taken, then, in the first place will be the sum of blood cells and plasma. Tubes used in this manner are named, according to Koeppe, "oil pipettes." Such a method is employed when one does not wish to mix the blood with the other solutions. When one dilutes the blood with some of the above-mentioned diluents, the unoiled, clean, dry tubes are used, and the operation is as follows: Blood is drawn into one of the tubes, with the condition that it is not to be drawn above the hundredth mark; the tip of the tube is then wiped, and the quantity read off accurately. Then the point of the tube is immersed in one of the standard solutions in the watch glasses, and a quantity of the latter is very slowly sucked up. There should be six or ten times as much of the solution as there is blood. The more of the diluting fluid employed the more accurate the results will be. Then the tube with the mixture is well shaken and centrifuged until two or three successive readings correspond. Ordinarily it takes about three minutes to centrifuge sufficiently. The readings are then placed into a table similar to the following, and the deductions found later:

	n=volume of blood taken	m=volume of blood corpus.	$\frac{100\,m}{n}$ = per cent. blood corpus.
1. "Oil Pipetta."	....	....	....
2. Blood diluted with weak solution ...	....	....	....
3. Blood diluted with strong solution..	....	....	....

To have a check on one's results, two or three such tests should be made in each case. (Koeppe filled eight or nine of these tubes in ten minutes, ready for the centrifuge.) Then all the tubes are centrifuged at one time, and the various tests on the same case should be alike. The volume per cent. is then figured out from the results according to the formula, 100 *m* divided by *n*. in which *m* is the volume of blood corpuscles and *n* the volume of the blood taken.

Calculation of the Lowering of the Freezing Point from These Results (Sommer): Following are tabulated results, taken, as an example, when potassium bichromate solutions, with a freezing point of —0.335° C. for the weak and —0.81° C. for the strong solutions are used:

	n.	m.	$\frac{100\,m}{n}$
1	52	26	50 per cent.
2	69	39	56.52 per cent.
3	66	27	40.91 per cent.

In the mixture with the weak fluid, the blood corpuscle per cent. is 56.52, while with a strong solution it is 40.9 per cent. The dissimilarity between the freezing points of the two solutions is .455 C., and this corresponds to a difference of 15.61 per cent. in the volumes of blood corpuscles in Experiments 2 and 3. Therefore, 1 per cent. of this variation is equivalent to 0.029148° C. of the diversity of the freezing points of the two diluting fluids. Since the difference between the volume of the blood corpuscles with the weak solution and the undiluted blood is 6.52 per cent., the variation in the freezing points between these samples of blood will be 6.52 times —0.029148° C. = —0.190° C. We must add this difference to the solidifying point of the weak solution, i e., we must add —0.190 to 0.355 = 0.545° C., which is, therefore, the freezing point of the undiluted blood. In order to bring these results into a formula, we will use the following symbols commonly employed in cryoscopy:

---

[20] Koeppe: Phys. Chemie, in der Medizin, Wien, 1900.

[21] Sommer, R.: Written communications.

[22] Beckman: Zeitschr. f. Phys. Chemie, vol. viii, p. 323.

d = Freezing point of the blood.
d_1 = Lowering of the freezing point of the weak solution.
d_2 = Lowering of the freezing point of the strong solution.
v = Per cent. of volume of the blood corpuscles in undiluted tube.
v_1 = Per cent. volume of the blood corpuscles when the blood is mixed with the weak solution.
v_2 = Per cent. of volume when it is diluted with the strong solution.

$$\text{Therefore } d = d_1 + \frac{(d_2 - d_1)\ (v_1 - v)}{(v_1 - v_2)}$$

In the illustration above:

$d_1 = 0.355°$ C.
$d_2 = 0.81°$ C.
$v^2 = 50$ per cent.
$v_1 = 56.52$ per cent.
$v_2 = 40.91$ per cent., and
$d = -0.545°$ C.

Precautions: 1. In using the Beckmann[22] apparatus for urine, the usual well-known precautions should be observed.

2. The ordinary precautions of asepsis used in all blood examinations should be adhered to.

3. In drawing up the blood into the tube, care should be taken not to permit it to pass beyond the hundredth mark, for accurate reading would then be impossible. If this accident occurs, the tube must be laid aside and another taken.

4. The diluting solution should be drawn in immediately after the blood and thoroughly shaken before placing the same into the hematocrit arm.

5. At least five minutes must elapse between mixing and sedimenting, to allow for full osmosis. Ten minutes is safe at the other extreme.

6. Since it is impossible to obtain accurately the same amount of blood each time, the per cent. volume should be figured in decimals to four places.

7. Before using the tubes they should be thoroughly cleansed, rinsed with water, then with potassium hydrate, and this followed successively by water, alcohol and ether and finally dried over a flame. In order to dissolve the blood corpuscles after centrifuging, a weak acetic acid solution may be used, followed by the above routine.

8. The freezing points of the standard solutions must be frequently taken to insure uniform results.

9. The point of the hematocrit tubes should be wiped dry before clamping, and the rubber washers should fit tightly to the ends of the tubes when clamped.

OBSERVATIONS ON TWENTY-FOUR CASES OF PNEUMONIA.

Before beginning the determination of the freezing points of the blood and of the urine of pneumonic patients, experiments were made on ten normal males between the ages of 20 and 40. These results were looked on as controls.

	Freezing point of blood.	Urine.
Case 1....	—.563 degrees C.	—1.53 degrees C.
Case 2....	—.566 degrees C.	—1.88 degrees C.
Case 3....	—.533 degrees C.	—1.77 degrees C.
Case 4....	—.544 degrees C.	—2.34 degrees C.
Case 5....	—.554 degrees C.	—2.16 degrees C.
Case 6....	—.558 degrees C.	—1.93 degrees C.
Case 7....	—.569 degrees C.	—2.06 degrees C.
Case 8....	—.55 degrees C.	—1.94 degrees C.
Case 9....	...557 degrees C.	—1.73 degrees C.
Case 10....	—.554 degrees C.	—1.16 degrees C.

(Twenty-four-hour specimens of urine were obtained throughout these experiments.)

From this it will be seen that the freezing point of the blood in these cases ranged from —0.533° C. to —0.569° C., average —0.552° C., while that of the urine ranged from —1.16° C to —2.34° C., average —1.8° C.

In comparing the results recorded in using the hematocrit method described above with those found when using the method employing the Beckmann apparatus, it was found that the freezing point of the blood, according to the latter method, was slightly higher than that obtained by the former. The difference is, no doubt, due to the accuracy of the former in carrying out the decimals to five places in all cases.

Appended are the tabulated results of twenty-four cases of pneumonia, taken under observation. These patients were watched daily. The freezing point of the blood and of the urine, the quantity of urine, the specific gravity of the urine and the amount of urea were recorded. Note was made of the casts and albumin when present.

Case 1.— S. S., ward 22; No. 74. Male, 32 years old. Right upper and middle lobes consolidated. Milk diet; stimulating treatment only. The course of the disease was moderate.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.60		Delirious.			102.6	102	32
2....	—.5976		Delirious			102.4	98	28
3....	—.585	—2.73	850	1023	3.1	100	100	28
4....	—.594	—2.64	890	1022	3	100	108	24
5....	—.602	—2.67	830	1023	2.9	102	100	28
7....	—.594	—2.57	1020	1021	2.9	100.2	92	28
8....	—.5617	—2.15	1200	1019	2.3	100.4	100	28
9....	—.563	—1.93	1130	1019	2.3	100.4	98	28
12....	—.547	—1.80	1400	1016	1.9	99	84	20

This patient was seen about five days after admission to the hospital. No chill had been noted. The course of the disease was moderate without complication. The temperature receded by lysis. The freezing point of the blood was lower than normal throughout the course of the disease. The freezing point of the blood rose as the temperature fell, not reaching normal until several days after the temperature. The urine followed the same course.

Case 2.—Y. F., Ward 22, No. 72. Male, 35 years old. Right lower and middle lobes involved. Milk diet; stimulating treatment. The course of the disease was moderate.

Day.	freezing. Blood	freezing. Urine	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.574	....	....	....	..	103	108	36
2....	—.60	—2.36	1020	1019	2.8	103	120	40
3....	—.5897	—2.58	970	1021	2.9	102.6	120	44
4....	—.5976	—2.96	860	1023	3.1	101.8	126	48
5....	—.593	—.287	1300	1021	2.9	99	96	48
7....	—.588	—2.59	1250	1019	2.7	100	88	28
8....	—.563	—2.03	1230	1018	2.4	99.6	92	32
9....	—.557	—1.79	1200	1018	2.2	...	Normal.	..
10....	—.553	—1.77	1330	1019	2	...	Normal.	..
14....	—.559	—1.59	1450	1017	1.7	...	Normal.	..

This patient was seen the second day after admission, about five days after the chill. His temperature was not very high. The freezing point of the blood and of the urine were moderately lower throughout the disease, rising slightly above the normal after the crisis, *then receding to normal.*

Case 3.—K. H., Ward 24, No. 3. Male, 32 years old. Upper right lobe involved. Milk diet; stimulating treatment. Moderately severe course.

Day.	Blood Freezing.	Urine Freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.627		Delirious.			102.8	110	34
2....	—.603		Delirious.			103	104	32
3....	—.594		Delirious.			102.8	120	34
4....	—.602		Delirious.			97.9	96	30
5....	—.583		Delirious			98.8	102	28
7....	—.577	—2.98	1050	1022	2.7	98.4	92	24
8....	—.547	—1.51	1230	1018	2	99	88	24
9....	—.548	—1.63	1420	1019	2	Normal.	Normal.	..

This patient was seen the second day after admission. The freezing point of the blood was considerably lower. The patient was delirious throughout until after the crisis, after which the freezing point of the blood rose to normal within a few days, as did also that of the *urine*. No specimen of urine could be obtained until after the crisis, but when obtained, the freezing point was considerably lower than it was after convalescence.

Case 4.—W. H., Ward 22, No. 34. Male, 27 years old. Right upper and middle lobes consolidated. Milk diet; stimulating treatment. Mild course.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.564	....	....	....	..	102	112	40
2....	—.587	—2.21	850	1020	2.6	100	100	44
3....	—.5628	—1.98	920	1019	2.5	102	100	36
4....	—.574	—2.37	890	1021	2.9	97.2	90	36
5....	—.585	—2.09	980	1019	2.6	98.6	84	28
7....	—.542	—1.76	1150	1018	2.3	98.6	72	24
8....	—.54	—1.71	1080	1018	2.1	Normal.	...	20
9....	—.542	—1.82	1200	1017	2.3	Normal.	...	..
10....	—.541	—1.76	1490	1018	2.2	Normal.	...	..
13....	—.557	....	....	....	..	Normal.	...	..

A very mild case, seen five days after he had the chill. The freezing point of the blood was only slightly lower throughout, coming up to normal, as in the preceding cases.

Case 5.—F. F., Ward 24, No. 40. Male, 24 years old. No definite area of consolidation. Milk diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.585	....	....	....	..	103	104	34
2....	—.57	—1.95	1020	1019	2 8	102	100	32
3....	—.563	—2.49	900	1021	2.9	100	90	30
4....	—.558	—2.37	920	1020	2.7	98.2	96	28
5....	—.552	—2.01	1030	1018	2.4	98.4	94	24
7....	—.533	—1.47	1270	1018	2	98.6	82	22
8....	—.536	—1.68	1150	1019	2	Normal.	Normal.	..
9....	—.541	—1.73	1090	1018	2.2	Normal.	Normal.	..
12....	—.55	—1.75	1200	1017	2	Normal.	Normal.	..

This patient was seen the day after admission. The course of the disease was typical, although no definite area of consolidation was found. The temperature fell by crisis the fourth day after coming under observation. The freezing points of the blood and of the urine were lower, but not markedly so.

Case 6.—C. J., Ward 10, No. 8. Male, 37 years old. Upper and middle lobes involved. Light diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.594	....	....	....	..	103.2	104	52
2....	—.584	—3.06	750	1025	3.2	101.2	112	36
3....	—.582	—2.93	890	1023	2.9	100.6	112	32
4....	—.585	— 2 87	850	1023	2.9	98.6	104	28
5....	—.582	—2.75	970	1020	2.5	98.4	98	26
6....	—.562	—2.24	1250	1017	2.4	99.6	92	30
8....	—.558	—1.79	1170	1018	2.2	99	96	26
9....	—.557	—1.93	1200	1018	2.3	Normal.	..	Normal
13....	—.562	....	....	....	..	Normal.	..	Normal

This patient had a high temperature, but no definite areas of consolidation were noted. The freezing points of the blood and of the urine were somewhat lower than normal, following the same course as in the foregoing cases.

Case 7.—W. A., Ward 24, No. 73. Male, 29 years old. Both lower lobes consolidated. Milk diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.589	....	....	....	..	102.4	100	30
2....	—.596		Delirious.			104	98	40
4....	—.611		Delirious.			103.2	120	42
5....	—.609		Delirious.			103.4	114	36
6....	—.617	—3.25	1100	1015	2.9	102	116	36
7....	—.591	—3.19	1200	1015	3	100	110	28
8....	—.593	—3.18	1250	1016	3	98	84	28
9....	—.559	—2.49	1560	1012	2.4	98.8	94	26
11....	—.541	—1.86	1400	1014	2	Normal.	Normal.	..
15....	—.563	....	....	....	..	Normal.	Normal.	..

(Casts and albumin.)

A typical case of pneumonia, with extensive involvement of both lower lobes of the lungs. The patient was seen early in the course of the disease. The freezing point of the blood gradually fell to reach its lowest point before the crisis, when, as the temperature descended, the freezing point of the blood rose to normal.

Case 8.—K. G., Ward 24, No. 1. Male, 27 years old. No definite area of consolidation. Milk diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.573	....	....	....	..	102.6	104	32
2....	—.599	....	....	....	..	102.4	102	30
3....	—.593	—3.06	1020	1023	2.8	101.6	94	30
4....	—.594	—3.07	890	1023	2.9	102.4	110	32
6....	—.589	—3.01	850	1024	3	98	94	24
7....	—.561	—3.00	1000	1019	2.7	98.6	88	22
8....	—.555	—2 37	1350	1015	2	98.8	84	20
9....	—.548	—1.99	1700	1016	2	98.4	80	22
10....	—.551	—1.75	1500	1015	1.8	98.6	82	20
11....	—.56	—1.87	1400	1016	2	Normal.	Normal.	..

This case, although not so severe as Case 7, followed the same course and gave the same results.

Case 9.—N. A., Ward 24, No. 4. Male, aged 19. Right upper lobe extensively involved. Milk diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.587	....	....	....	..	104	116	30
2....	—.589		Delirious.			103.2	110	38
3....	—.591		Delirious.			104.4	124	52
5....	—.594		Delirious.			99.2	80	30
6....	—.558	—2.08	700	1021	2.7	99	60	26
7....	—.562	—1.87	900	1020	2.4	99.2	66	28
8....	—.554	—1.83	1050	1018	2.2	Normal.	Normal.	..
9....	—.543	—1.92	1020	1019	2.3	Normal.	Normal.	..
10....	—.541	—2.01	1160	1021	2.5	Normal.	Normal.	..
13....	—.552	....	....	....	..	Normal.	Normal.	..

A very severe case of short duration. The freezing point of the blood and of the urine followed the same course as in the other cases.

Case 10.—L. J., Ward 24, No. 38. Male, 18 years old. No definite area of consolidation. Milk diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.602	....	....	....	..	104.8	112	30
2....	—.569	—1.93	950	1022	2.6	104	120	28
3....	—.5827	—2.23	850	1023	2.7	104.2	120	40
5....	—.538	—1.23	1200	1017	2	99	94	30
6....	—.549	..1.39	1100	1017	2	99.2	80	28
7....	—.543	—1.55	1060	1018	2	98.9	80	24
8....	—.547	—1.69	1080	1018	2	Normal.	Normal.	..
9....	—.546	—1.71	1440	1018	2.3	Normal.	Normal.	..
10....	—.549	—1.67	2100	1017	2	Normal.	Normal.	..
11....	—.558	....	....	....	..	Normal.	Normal.	..

This patient had a high temperature, but no definite areas of consolidation were noted. The freezing points of the blood and of the urine were somewhat lower than normal, following the same course as in former instances.

Case 11.—E. J., Ward 24, No. 79. Male, 47 years old. Lower left lobe consolidated; also had pleurisy on left side.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.611	....	....	....	..	104	132	36
2....	—.607		Delirious.			102.4	115	28
3....	—.623	....	....	....	..	102.8	106	28
4....	—.613	—3.59	870	1024	3.1	98.8	82	22
5....	—.617	—3.59	720	1028	3.4	99.4	90	20
6....	—.587	—3.19	820	1018	3.1	98.6	90	20
7....	—.549	—2.05	1250	1014	2.6	98 6	80	24
11....	—.555	—1.96	1400	1015	2	Normal.	Normal.	..

A very severe case; high temperature and rapid respiration. The freezing point of the blood was considerably lower, as was also that of the urine. The same general course was present, however, as in preceding cases, relative to the lowering of the freezing points of the blood and of the urine.

Case 12.—M. A., Ward 22, No. 38. Male, 30 years old. No definite area of consolidation. Milk diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.593	....	....	....	..	103.4	120	48
2....	—.597	—3 11	680	1029	2.9	98	96	32
3....	—.591	—3.15	820	1026	2.8	98	86	30
4....	—.576	—2.97	1230	1021	2.4	98.8	70	22
5....	—.555	—1.75	1400	1017	2	98 8	72	22
6....	—.545	....	....	....	..	Normal.	Normal.	..
9....	—.546	....	....	....	..	Normal.	Normal.	..

This patient came into the hospital late in the course of the disease, the crisis occurring on the same day. The same findings obtained as in the other cases.

Case 13.—K. J., Ward 22, No. 28. Male, 46 years old. Right lower lobe consolidated. Stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp
1....	—.591	....	....	....	..	102.4	112	40
2....	—.587	—2.805	820	1021	2.5	101.8	104	36
3....	—.593	—2.96	760	1022	2.8	97.6	100	32
4....	—.591	—3.05	930	1026	2.9	99.6	88	32
5....	—.555	—3.02	1230	1021	2.3	99.4	98	28
7....	—.541	—2.47	1450	1015	2	99	100	30
10....	—.543	....	....	....	..	98.8	96	22

(Anemic and weak.)

This patient was seen the day after admission to the hospital. The freezing points of the blood and of the urine were low. It was noted that immediately after the crisis both were lower than during the disease.

Case 14.—D. J., Ward 24, No. 30. Male, 42 years old. Right lower and middle lobes. Stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.599	....	....	....	..	103.2	100	36
2....	—6.05		Delirious.			104 4	110	44
3....	5.94	—2.14	950	1021	2.7	102.4	90	34
4....	—.583	—2.10	1020	1021	2.8	101	98	30
5....	—.556	—1.78	1300	1017	2.4	99.4	90	26
6....	—.55	—1.60	1500	1015	2	98.6	86	24
7....	—.556	—1.70	1650	1014	2	98.4	80	26
12....	—.557	....	....	....	..	...	...	..

A severe case, the patient being delirious during the first two or three days. The freezing point of the blood was low. The patient made an uneventful recovery. Freezing points of the blood and urine came to normal, as in preceding cases.

Case 15.—D. M., Ward 24, No. 32. Male, 33 years old. Right lower lobe involved; continuous salt irrigation. Stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.583	....	....	....	..	100.2	100	36
2....	—.587	....	....	....	..	101.8	100	28
4....	—.585	—2 25	920	1015	2.6	99.8	84	26
5....	—.571	—2.15	1020	1017	2.7	99.6	88	30
6....	—.555	—1.85	1300	1014	2.2	99.2	76	24
10....	—.560	—1.80	1700	1015	2	98.6	78	22

A mild case. The same course and findings existed as in former cases. This patient also made an uneventful recovery.

Case 16.—H. C. H., Ward 22, No. 68. Male, 42 years old. Right upper lobe consolidated. Evidences of tuberculosis. Milk diet; stimulating treatment. Anemic.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.603	....	...	....	..	102	120	34
2....	—.604	—2.47	900	1018	2.8	103.2	100	36
3....	—.618	—2.13	950	1019	3.1	100.2	98	36
4....	—.59	—2.39	600	1020	3.2	99.8	90	36
5....	—.60	—2.53	250	1019	3	100	84	28
7....	—.554	—2.11	870	1018	2.8	100	88	28
8....	—.532	—2.02	750	1019	2.6	100.5	90	28
9....	—.533	—1.97	830	1020	2.5	100.2	92	28
12....	—.535	....	...	....	..	99.6	86	26

Another typical case of pneumonia. The freezing point of the blood was low, as was that of the urine, following the same course as the preceding, but it is to be noted that evidences of tuberculosis were found, and therefore the higher freezing point of the blood during convalescence (Koranyi[8]).

Case 17.—V. B., Ward 24, No. 36. Male, 27 years old. Right lower lobe consolidated. Evidences of tuberculosis. Milk diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.589	—2.93	750	1023	2.7	102	88	32
3....	—.593	—2.97	720	1024	2.8	102.6	102	28
4....	—.591	—2.87	800	1023	2.8	100	96	28
5....	—.616	—3.03	690	1025	2.9	100.6	95	24
6....	—.607	—3.14	870	1029	3.2	102	96	28
7....	—.608	—3.02	1020	1021	3.1	100	80	26
8....	—.572	—2.61	970	1019	3	99	97	24
10....	—.53	—2.47	1200	1015	2.6	99.2	88	28
13....	—.534	....	....	....	..	99.6	92	26

This patient was seen a day after admission with a typical pneumonia history. The freezing points of the blood and of the urine were low. They gradually descended until the temperature began to fall, when they gradually rose to normal. It will again be noted that this patient had evidences of tuberculosis, which will account for the rather high freezing point of the blood after crisis and during convalescence.

Case 18.—B. Z. V., Ward 10, No. 22. Male, 45 years old. Right lower lobe consolidated. Chill several days before admission.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.593	....	....	....	..	104.2	124	30
2....	—.619	—3.29	530	1032	3.3	103.5	132	30
3....	—.601	—3.24	720	1028	3.2	99.2	96	28
4....	—.587	—2.51	1120	1019	2.6	98.8	80	24
5....	—.593	—2.60	1050	1021	2.8	103.8	140	44
7....	—.644	—2.91	870	1023	2.9	103.2	132	38
8....	—.689		Delirious.			103 2	128	40
9....	—.838		Delirious.			104.6	148	48

This patient was seen the day after entrance into the hospital, with the right lower lobe consolidated, high temperature and high pulse. The freezing points of the blood and of the urine were low. On the third day the patient had a crisis and the freezing point of the blood and of the urine began to approach normal. Two days later the patient had a relapse, with high temperature, high pulse, and rapid respiration. Physical examination now showed an extensive consolidation of the right lung, anteriorly and posteriorly from above down to the lower border of the scapula. The patient became considerably worse and delirious. On the seventh day the freezing point of the blood was very low. The patient was cyanotic and oxygen had to be administered. The patient died the night of the ninth day. The freezing point of the blood preceding his death was —0.838; temperature, pulse and respiration were very high.

Case 19.—A. G., Ward 10, No. 25. Male, 50 years old. Upper left lobe extensively consolidated. Milk diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.573	....	...	....	..	103	112	48
2....	—.592	—2.87	700	1023	3.1	102.2	96	36
3....	—.603	—3.17	560	1027	3.5	102.8	86	48
4....	—.813	—3.21	430	1032	3.6	102.8	120	46
5....	—.834	....	...	....	..	102.8	140	48
6....		Patient died.				103.6	138	52

The last blood for estimation was taken an hour before death—oxygen was administered for last twenty-four hours following venesection, withdrawing 500 c.c. blood and injecting 850 c.c. normal salt. In this case it was noted that on the fourth day the patient was very cyanotic, and since the pulse was slow a venesection was performed, withdrawing 500 cubic centimeters of blood. Eight hundred and fifty cubic centimeters of salt solution were then injected. It will be noted that this did not alter the results of the freezing of the blood, the same descending nevertheless. Oxygen was administered during the last twenty-four hours. Patient died of heart failure. The freezing point of the blood before death was remarkably low.

Case 20.—J. O., Ward 22, No. 9. Male, 44 years old. Left and right upper lobes involved. Milk diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.579	....	...	....	..	102	120	40
2....	—.694	—2.27	830	1023	2.7	103.2	124	44
3....	—.835	—2.31	850	1023	2.8	104.6	136	48

(Patient died next morning.)

While not so severe on entering, the freezing point of the blood was not very low, but it gradually descended so that on the day before his death it was very low.

Case 21.—Ward 24, No. 65. Male, colored, 35 years old. Right lower lobe consolidated. Milk diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.588	....	No specimen.		....	102	120	38
2....	—.687		Delirious.			102.6	108	52
3....	—.811		Delirious			103.2	120	48

Became suddenly worse and died. Case very similar to the preceding.

Case 22.—P. C., Ward 10, No. 3. Male, colored, 30 years old. Lower left lobe consolidated. Venesection and injection of salt solution 500 c.c. and 600 c.c. on entrance. Stimulating treatment. Syphilitic history:

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.615		No specimen.			103.6	148	36
2....	—.62	....	...	....	..	102	132	42
3....	—.73	—1.13	500	1012	1.5	104.5	70	50

Another fatal case, very severe, and brief in its course. The patient died on the third day after admission. The freezing point of the blood became very low before death. The patient died of heart failure.

Case 23.—M. J., Ward 10, No. 6. Male, 20 years old. Lower left lobe involved. Spread to upper lobe and right lower lobe third day.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.591	....	...	....	..	101.8	106	28
2....	—.607	—2.05	830	1026	2.8	102.4	122	32
3....	—.608	—3.03	880	1026	2.9	103.4	120	30
4....	—.715	—3.10	720	1030	3.2	103	124	44
5....	—.837		Delirious.			104.3	140	56

Patient died from exhaustion and heart failure. Oxygen was administered before death. Died the night after last record given. A very severe course. Patient died on the fifth day, showing same findings as preceding fatal cases.

Case 24.—O. C., Ward 24, No. 78. Male, 49 years old. Right lower and middle lobes consolidated. Normal salt per rectum every four hours. Milk diet; stimulating treatment.

Day.	Blood freezing.	Urine freezing.	Am't.	Sp. gr.	Urea.	Temp.	Pulse.	Resp.
1....	—.611	....	...	....	..	102.4	136	32
2....	—.623	Involuntaries.		....	..	105.3	140	40
3....	—.702	—3.25	720	1031	3.4	103.8	120	36
5....	—.728	—3.24	350	1030	3.2	106	144	42

(Patient was delirious. Died 3 a. m. next morning.)

This was a very severe case. The patient died on the fifth day after admission to the hospital. It will be noted that the freezing points of the blood and urine in this case were low, the freezing point of the blood being lowest before death. The patient died of heart failure.

The chlorids in the urine were also estimated in the above experiments. The following method (approximate) was used:

Urine, 5 c.c.................
HNO_2, 10 gtts................
$Agno_3$ 10 per cent. sol., 2 c.c..
} Shake, and note amount of precipitate.

The chlorids were found markedly diminished in amount up to the crisis, when they rapidly increased to above normal quantity, to recede later during convalescence.

In reviewing and summarizing the above data, it is to be noted that all the patients were males between the ages of 18 and 50, and were apparently healthy before taken sick with pneumonia. This excludes, therefore, differences which might be peculiar to the disease as manifested in children and old age. All the patients were on essentially the same diet: Milk, and later broths and plenty of water. As to the treatment, only regular stimulating treatment was given, consisting of strychnia, whisky or digitalis. A few mentioned had salt irrigations. I believe that, in view of the results tabulated above, the following conclusions will be considered logical and proper:

CONCLUSIONS AS TO BLOOD.

1. There is an absolute lowering of the freezing point of blood in pneumonia.
2. The freezing point lowering of the blood depends in some way either on the extent of consolidation of the lung or on the height of the temperature, or both.
3. The lowering of the freezing point of the blood is greater than would be accounted for by the increased venosity of the blood, due to deficient aëration in the lungs.
4. The concentration of the blood increases, as shown by the lowered freezing point, as the disease progresses up to the time of crisis. Some time is necessary for the elimination of the excessive accumulation of products in the blood. Hence, several days elapse before the freezing point of the blood rises again to normal.
5. In those cases where the heart weakens perceptibly, the freezing point of the blood becomes lower. In the fatal cases in which the heart gives out, the freezing point of the blood is extremely low.
6. The lowered freezing point of the blood is apparently not due to deficient kidney function, but may be due to the inability of the kidney to excrete the excessive products of metabolism.

CONCLUSIONS AS TO URINE.

1. The freezing point of urine in pneumonia is considerably lowered.
2. This lowering is greater than would be accounted for by a mere concentration of normal urine.
3. The chlorids excreted are constantly diminished, due to a decrease in amount taken in (Sollmann).
4. The freezing point of the urine times the number of cubic centimeters voided is increased.
5. The quantity of urine is decreased, whereas the freezing point is lower.
6. The lowering of the freezing point of the urine is not due to chlorids, but to metabolic molecules excreted.
7. The freezing point of the urine does not rise to normal until after that of the blood, that is, several days after the crisis.
8. The specific gravity of the urine is not an accurate index to the concentration of the urine.
9. The freezing point of the urine bears no constant relation to that of the blood normally, for in a case with a freezing point of blood at —0.54° C. the freezing point of the urine may normally be lower than in a case in which the freezing point of the blood is —0.57° C. or *vice versa*.

I wish here to express my thanks and gratitude to Prof. F. R. Zeit for suggesting this problem and directing the work; to Dr. W. H. Buhlig for many valuable suggestions, and to the directors of the laboratory and internes of the Cook County Hospital for assisting me to find the material.

PLEURAL EFFUSIONS IN CHILDREN.*

C. F. WAHRER, M.D.
FORT MADISON, IOWA.

These affections are probably as old as the creation of man, as the conditions producing them must have obtained ever since man first became sick. Hence, I scarcely think that much that is new can be said on the subject; it is possible, however, that I may say something that will cause some one to search deeper than ever before, and thus enable him to save a life that otherwise would have been sacrificed. But the best motive I have in writing is to provoke some discussion that may throw more light on diagnosis or treatment that may prove of benefit to the practitioner and to the one mostly concerned, the patient.

These pleural effusions, though fairly easily diagnosed by the expert, are too frequently overlooked by the rank and file of the profession, and, secondly, often when diagnosed, are not treated with sufficient vigor, but allowed to drift on expectantly, when only radical measures should be employed and thus give the patient the best chance and the most certain promise of recovery. It may seem strange to some of you whose daily life in large cities is so full of scientific certainty that I should make such observations unless you come in contact, more than I am aware, with that large number of routine physicians who are willing to bear or, rather, let their patients bear what they, either through ignorance or shiftlessness, are not able or willing to take the trouble to help. But some of you are, as I have been, a teacher, and you certainly remember some of the material that came before you as students and who graduated in medicine from your classes, I am sure, with many misgivings on your part. The power to generalize, and from that foundation to specialize, is not given all people; the ability to intelligently make comparisons, as we do in diagnosis, is not easy alike to all, even when they have a large stock of facts on hand. Hence, I want to emphasize this fact that throughout this great country of ours many patients with pleural effusions, both old and young, especially the latter, go to their deaths with the disease unrecognized by the attendant. You know, if these are not properly treated, and it must be surgically, that the vast majority will prove fatal.

First, there is a widespread idea that all pleural effusions must arise from a preceding attack of pleurisy. A little reading in pathology and text-books on diseases and their etiology would soon remind us such is not the case. Most cases in children, perhaps nine-tenths of them, have their origin in pneumonia—especially that form termed pleuropneumonia—yet many cases of effusion are secondary to Bright's disease, scaret fever, rheumatism, amyloid disease, trauma, heart affections, typhoid fever, syphilis, affection of the spleen, articular inflammations, pertussis, osteomyelitis, appendicitis and others, not the least of which is tuberculois. For reasons not supported by experience, it has een the routine of fashion to consider nearly all cases f pleural effusions of tuberculous origin, and, while it is not good practice to ignore tuberculosis as a factor in the etiology, yet there is no good reason to overemphasize it. There are many more of these tuberculous in adults than in children, in the ratio of 4 to 8 mes as many. This is as it should be, as we find many more cases of tuberculosis in adults than we do in children, especially in early childhood. It is most asonable to think of the reverse, namely, that conmptives may be liable to pleural effusions as well as her people.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

There are many other errors not only in etiology and anatomy, but in the pathology, prognosis and treatment of these cases. For instance, we speak of the pleural cavity. Physiologically and anatomically it may be said there is no such cavity. Only when filled with pathologic products do we have such a cavity—when filled with serum, pus, chyle, blood or air. Then the layers of the pleura normally contiguous become separated and a cavity forms, filled with these products. These fluids usually first make their appearance in the costophrenic sinus, then extend laterally and upward. When pleural exudates are examined we find many pathologic micro-organisms in them, often defining the character of the origin of infection. Staphylococci, streptococci, pneumococci, tubercle bacilli, gonococci and others. I am firmly convinced that the presence of any of the pathologic micro-organisms in sufficient numbers may provoke enough irritation to produce a pleurisy with an accompanying effusion.

As far as anatomy of the parts involved is concerned, it will not be necessary to go into detail, for text-books on anatomy and diseases of children will furnish that information more fully than I can, but will only draw your attention to the fact that the anatomy of the respiratory apparatus differs from that of the adult in that the pleural sinuses are deeper in children; hence, in puncturing an effusion it may be well not to wound the diaphragm, which rises comparatively high in the child. Even the stomach or intestines might be wounded if one should forget these relations. The relations of the two sides must be kept in mind. The pleural sinus of the left side is deeper than on the right, owing, perhaps, to size and position of organs on right side. The liver, especially large in the child, pushes the right lung up. The right lung is also smaller or shorter than the left lung. So when aspirating it is well to use the posterior axillary line, as that would lead to the most central point of all effusions—and to use the sixth or seventh interspace on the left side and the fifth or fourth on the right side, of course, combining these anatomic relations with each individual case.

As diagnosis in some cases is difficult, all the more should we use care in not allowing a case to escape us undiagnosed. Ordinary percussion and auscultation carefully made, excluding pulmonary and respiratory affections, and when in doubt coupled with the use of an exploratory aspiration, will, in painstaking hands, usually lead to a correct diagnosis. Pleural sounds, especially in dry pleurisy and serofibrinous pleurisy, by auscultation, imitate the creaking of a compressed snow ball or fine creaking sole leather. The breathing is of the bronchial variety. Percussion yields dullness, but in some cases when the child lies down the effusion may settle to the lowest point and, surmounted by gas or viscera, may give resonance and thus deceive. Diagnostic signs in effusions are rather deceiving, because both percussion and auscultation sounds vary owing to position of the child and number of places of adhesions. Percussion usually reveals flatness; absence of râles, friction sounds and bronchial breathing are found on auscultation. We also notice cough, pain, diminished fremitus, intercostal bulging of affected side, intense dyspnea, paleness and anemia, decubitus on diseased side by preference, and when all these signs do not give a satisfactory diagnosis they may be supplemented, as before mentioned, by exploratory aspirations; even then the latter procedure in careless hands may prove unsatisfactory and appear negative when effusion is present. The needle may be too small and may become occluded with coagula, the precise position of the effusion may not be reached by not going far enough or too far, being placed too high or too low; the aspirating apparatus may be faulty; in short, when effusion is strongly suspected and exploration is at first negative many patient and careful trials should be instituted before failure is to be accepted. It is scarcely necessary to add that all such efforts must be carried out only under most pedantic care as to asepsis, and the old surgical maxim, "*Nil nocere*," is here paramount.

The character of the effusion can by no means be diagnosed except by the exploratory method. It may be grossly stated as a matter of presumption that in children of 3 and under, the effusion is purulent. The difficulty of diagnosis is increased when an effusion is encapsulated, when it is a subphrenic abscess or when it is an empyema necessitatis, as the latter may be mistaken for superficial abscess, eroded or gangrenous rib or trauma or the outlet of some burrowing abscess, as, for instance, a perinephric or psoas abscess. But in cases of pleuropneumonia the effusion may be masked by the prominent symptomatology of the pneumonia, but this alone should put the attendant on his guard, especially if he have a case of retarded resolution, for an empyema may be mistaken for a case of delayed recovery in pneumonia. Many cases of empyema are often very insidious in onset and behavior, but if you will remember the proneness of children to develop effusion after respiratory diseases, after scarlatina, tuberculosis, pertussis, rheumatism, endocarditis, liver diseases, kidney affections and those of the spleen, especially when coupled with an increased leucocytosis, it is better to suspect empyema and act accordingly. Now, I do not imply that one should go to extremes and diagnose everything as effusions simply because we can not make it out a case of malaria or fits, but let us use caution and not be humiliated and fail in our diagnosis and lose a valuable, promising life that should by all means have been saved, for, while most undiagnosed cases will die *per contra*, nearly all properly treated cases recover in children, and that is my other chief contention in this paper, to which I will refer under treatment.

I wish to emphasize prognosis. This, especially in children, is good, but must materially depend on the treatment, the skill of the attendant and especially the faithfulness with which a positive line of treatment is carried out. It also depends much on the primary disease that gave rise to the effusion and the length of time the patient has been afflicted. It is most unfavorable when the diagnosis has been delayed, where too much stress is placed on expectancy or, what amounts to about the same, medical treatment, when primary disease has seriously invaded or destroyed some of the principal organs, such as the kidney, lung, heart, endocardium or pericardium, in amyloid degeneration of the liver, also when operation is delayed too long. Prognosis is good when early diagnosis is made, when operated on early by proper method, when child's general condition is good, and causative disease has not made too serious inroads on the patient's constitution. But, to repeat, in general it may be stated the prognosis is better than in adults in proportion of two to three times as good. Of course, under 1 year of age the mortality is great, probably 50 per cent. of deaths; however, at that age the disease is rare. Also when the disease is bilateral, a rare condition. Some of my chief reasons for a better prognosis in children is that we have a more active metabolism, a smaller cavity, where in this case real, and not relative size, counts—a greater elasticity of chest wall so the cavity can more readily contract or collapse, a condition much to be desired. It may be well to pause here long enough to remind you that fully nine-tenths of all cases usually follow pneumonia, especially pleuropneumonia; the other one-tenth all the other causes previously mentioned.

I have already said enough to have committed myself to the treatment; that it must in the majority of cases be surgical. From the fact that over one-third of all cases of effusion are purulent, the treatment must be surgical; most of the others are serofibrinous and, while they often absorb under stimulation, poultices, heat and liniments and some other medical treatment, yet they would recover faster under incision, because the large fibrinous clots so frequently present can be mechanically removed instead of leaving them to tardy absorption and a possible prey to infection. The two chief surgical procedures are puncture and aspiration and incision with or without section of a rib or two. True enough, aspiration has cured some cases of effusion, both serous and purulent, yet why trust a doubtful method for one more certain? When we have a purely serous effusion, aspiration once performed, or once or twice repeated, will usually lead to a rapid recovery. The same is true when an incision is done for an empyema. It may be parenthetically stated that while children recover rapidly they also die very rapidly under operation if they succumb to it; so danger signals must be heeded. Aspiration may fail in such cases or it may delay the recovery; it may prolong the infection and thus endanger the recovery, and may also lay the foundation to a possible tuberculosis. As to accidents in operations, they are less liable than in adults.

Now, who should perform these operations? I claim that any physician who is competent to treat diseases at all should be able to aspirate a serous effusion or make an incision for an empyema in a child. Of course, it is self-evident that if a competent surgeon can be had it may be preferable to have him operate. In rare cases, and they are extremely rare, where an Estlænder operation is required or the more serious and extensive Schede procedure, the highest possible surgical skill is none too good.

I shall not worry you as to surgical methods, how to operate, the best methods of drainage and the other details; any modern text-book will supply this information if, indeed, any one is now present that may be in need of such. With a short report of two cases I will conclude.

Case 1.—Girl, 3½ years old, had pneumonia, following measles; was supposed to be suffering from delayed resolution. I was called in consultation about the thirtieth day of disease; found child of naturally fleshy and buxom habit, very emaciated, pale, cadaverous appearance, increased leucocytosis, hectic cough, great dyspnea, left intercostal spaces bulging, heart displaced to right, and other symptoms classical. On inspection found just above left nipple in fourth interspace a red spot ⅝ inch in diameter, appearing like a common boil; I diagnosed an empyema necessitatis, proved by aspiration. I made an incision two inches long, beginning with the external lesion and extending toward the left. Fully 40 ounces of pus of a rich, creamy appearance was removed under cocain anesthesia, double rubber drain introduced and child made a complete, uneventful recovery. This fine little girl would have died under her first attendant, who still treated her for pneumonia and grippe in a very dilatory manner, not even administering supportive measures.

Case 2.—Boy, 31 months old, had some respiratory disease diagnosed by his attendant as pleuro-pneumonia. On the thirty-first day of the disease the physician, a bright country practitioner, observed bulging on left side, heart displacement and other signs which he interpreted either pleural or cardiac effusion, not being certain which, and exploratory aspiration being denied him, he sent for me. Under cocain exploration was painlessly made, pus found at once and operation advised, which was done next day. This child was very thin, restless, cyanosed, pulse high, temperature 104.6, anxious expression of face and, as in other case, leucocytosis marked. Incision under local anesthesia was made in sixth interspace and between anterior and posterior axillary lines two and a half inches long. With each respiratory movement pus spurted out in streams. Child was held by father on lap, left arm raised high and placed around father's neck. After liberating about 50 ounces of pus patient got weak, I desisted further work, placed a double drain, dressed wound, bandaged and put child to bed. He also made a brilliant recovery, notwithstanding large quantities of pus were removed many times at subsequent dressings.

Both these children are now (one 4 years and the other 3 years since operation) in splendid health, whereas both would have helplessly perished without operation timely performed. True, cases of empyema necessitatis have spontaneously recovered, so have cases that ruptured into a bronchus, and pus expectorated, but it would be only proper to say of such that they got well in spite of poor treatment rather than that the attendant deserved any credit for their recovery.

In closing let me once more urge a thorough diagnosis in a painstaking, almost pedantic manner, with all clothing removed as well as bedding, leaving no means unused to confirm your findings. You may not believe me, but experience confirms me, too many auscultations are made with the unaided ear, too many percussions made through their clothes and poultices, and too many diagnoses arrived at by snap judgment processes and smart guesses.

It may not be amiss to remember that the microscope and blood counts may aid when we are in the dark, and that children having effusions usually die if badly treated, and almost always recover when treated correctly, fearlessly and courageously.

DISCUSSION.

Dr. A. C. Cotton, Chicago, agrees with Holt that the apex beat should be located if possible in every case of suspected empyema, even when the needle shows pus. Left-sided effusion, if extensive, ought to displace the apex beat. Otherwise the source of pus may be a pulmonary abscess. Dr. Cotton does not believe that Dr. Wahrer intended to convey the impression that he lost 50 per cent. of his cases. Some people's ears are built pretty well, and we have the authority of the Scriptures to let him who has ears to hear with his ears and not use the stethoscope.

DR. WILLIAM J. BUTLER, Chicago, is inclined to regard with great skepticism any diagnosis of effusion necessitating surgical interference when the dullness is obscured by slight change of the position of the patient.

DR. D. S. HARNSON, Cleveland, Ohio, believes that the diagnosis of pleural effusion can be made without the needle. Were he the child he should like that physician best who would make a careful examination and make the diagnosis without the needle because, simple as it is, it is both painful and unpleasant. A child with pleural effusion will nearly always lie on the back, and the man who carefully examines the back will nearly always make out these exudations very early.

DR. C. F. WAHRER stated that some of these patients go unrelieved and to their graves for want of proper diagnosis and treatment. In reply to Dr. Cotton's statement that 50 per cent. of cases is too great a mortality, he said that in children one year of age the mortality is great, and that the consensus of opinion of authors in this country and in Europe is that in about 50 per cent. of children under one year the mortality reaches 50 per cent. and over. The different sounds in auscultation and percussion vary as much as the number of authors speaking on them. Dr. Wahrer does not care about putting his ear on everybody's naked chest, and in some patients the intercostal space is so deep that his ear is not deep enough to place it in between. Those who depend on the unaided ear have not availed themselves of the best opportunities of making a diagnosis by the use of the stethoscope. In reference to Dr. Harnson's statement that he would prefer to have a diagnosis made without the needle, Dr. Wahrer said that there is no harm in inserting the needle into the chest if hands and instruments are pedantically clean. It is better to avail ourselves of all the diagnostic means rather than to let pity interfere with our best judgment.

THE MANAGEMENT OF TYPHOID FEVER IN CHILDREN.

A PLEA FOR ENTEROCLYSIS.*

W. C. HOLLOPETER, M.D.
PHILADELPHIA.

In attempting to give a very brief outline of my methods of managing typhoid fever in children, it is well to preface my remarks by saying that I will confine myself strictly to those methods which my experience has found most satisfactory; it is hoped that by so doing I may invite a free discussion and thus gain some additional knowledge on this perennial subject.

To manage a case of typhoid fever in a child successfully, we must be sure of our diagnosis and fully understand the child. An early diagnosis is not an easy matter, because the disease is frequently ushered in under the guise of some acute disorder which greatly postpones a decision. Usually the child has been ill for six or seven days before the physician is called. At this time we may find a temperature ranging from 101 to 104 degrees. The symptoms may strongly suggest enteritis, meningitis, pneumonia or autointoxication. Indeed, it may be doubted whether we ever manage a case of typhoid as typhoid before the end of the first week. Generally at this period we will arrive at a correct diagnosis, and then only by the process of exclusion.

Typhoid in children may be accompanied by diarrhea or constipation; the latter seems to be as frequent as the former. The spleen is often chronically enlarged, especially in children with rickets. This is a strong factor, however, in the diagnosis. The same is true of the liver. Chronic appendicitis comes in for its share of the blurring of an early diagnosis in typhoid. The general symptoms very frequently do not agree with the temperature, pulse or the physiognomy of the patient. In no other serious disease do we have the patient seemingly so well, in spite of some single, serious symptom. By reason of this conflicting array of early symptoms we frequently encourage relapses.

The Widal test and the diazo reaction are of very little value prior to the beginning of the second week, at this time we have additional symptoms to confirm the diagnosis, thus reducing the value of the Widal test. Undoubtedly most cases of chronic fever in children are diagnosticated by the process of elimination, and not usually before the tenth day, the only exception being where we have an overwhelming toxemia with few complications. Many cases of typhoid fever brought under my notice had been previously treated for pneumonia, and many cases were classified as typhoid which were chronic food poisoning.

Regardless of our pathology, for the sake of clinical study, typhoid may be regarded as a general sepsis, and any treatment that will lessen the toxemia and shorten the leakage in the general circulation may be regarded as a step toward a specific treatment. As yet, however, we have no specific treatment for typhoid fever. It is very interesting to notice, in passing, how frequently specific medication gains recognition for a time, its limitations conceded, and then it is discarded and quickly forgotten. The same may be said of the Brandt system, while tepid bathing has universal application.

It has been my privilege to see a large number of very severe cases of typhoid fever in children ranging between the ages of 6 and 15 years, the most susceptible age as well as the age when tact and care are at a premium.

To me it seems that the two elements necessary to success in combating this troublesome and dangerous disease are to reduce the toxemia and supply food and fluid. The first step is quietude in a large, well-ventilated room with calomel, which has not lost its reputation as an intestinal antiseptic, and a daily colon irrigation. The emphasis of the whole treatment I wish to place on the manipulation of the colon washing; this I order daily unless some grave counter indication obtrudes itself. Enteroclysis will reduce toxemia and necessarily the temperature, and at the same time supplies much needed fluid to the body. If this is carefully performed, it will be acceptable to the child and greatly shorten the period of illness. The temperature of the colon irrigation is always governed by the temperature of the child's body. All text-books give the technic of enteroclysis, yet I fear that the nurses fail to gain the desired results from this mode of treatment, because the attending physician does not impart specific instructions. Frequently I assist the nurse in the first treatment, thus allowing me to discover any abnormalities of the bowel, if any should exist, as I recognize its limitations as a therapeutic agent, and this must be done before valuable time is lost or any mischief occurs. If nurse and physician have gained the confidence of their little patient, the work will be performed pleasantly and profitably.

It must be remembered that the intestinal tract is the seat of many troubles and dangers during a course of fever. Tympanites may be troublesome by reason of some previous enteritis or peritoneal irritation; this is usually combated by colon to relieve this tympany. I frequently substitute bicarbonate of soda for the saline solution, or I may add tincture of asafetida or some aromatic infusion, such as chamomile or a small quantity of turpentine, if tympanites and pain are troublesome. If peristalsis is increased by the intestinal washing, I reduce their frequency; or, if necessary, throw into the bowel one or two ounces of starch or bismuth emulsion. If hemorrhage should occur, I use the cold enema and apply the ice externally in serious hemorrhage; ice suppository may be indicated as well as the ice bag externally. If the heart is weak, I use a small quantity of whisky in the clyster.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

I depend on the ice bag to the head and the hot water bag to the feet, as a routine, with a tepid sponge night and morning. Ice bag to heart, if fever is high. Throughout the illness observe a careful toilet of the nose and mouth. Change of position every two hours will serve to prevent pneumonia. Ice bag to the head need not be watched, except to see that it is not empty, but ice bag to the chest or back should not remain too long on one spot for fear of producing congestion of the kidney. I have found that children will submit more gracefully to the enteroclysis and the use of the ice and hot water bags than to frequent bathing, and on this account I have practically abandoned sponging every two hours if temperature reaches 102.2 degrees, which seems to be the classical treatment.

Diet, throughout the whole course of the fever, I have reduced to peptonized milk and albumin water. Whole milk is out of the question, even with children 15 years of age. As Jacobi says, "It is food for children in health, but food for bacteria in fever."

Even peptonized milk is better appropriated if taken with some charged water. I alternate the milk with the albumin water; the use of lemon and orange water is of inestimable value. If any drug is indicated—and I never give any except to meet a decided want—I administer it in a large glass of water. Last year I compared six cases with and without the free exhibition of water. In the six cases in which I forced a full glass of water with frequent intervals, the temperature reached the normal on an average two days earlier than in the series of patients who were allowed to drink the minimum quantity, thus demonstrating the value of fluid as an eliminator.

Retention in a recumbent position and on liquid diet I have found should continue for ten days after normal temperature has been reached.

In conclusion, let me say that I have no original thought to advance, but simply desire to emphasize the value of enteroclysis in typhoid and to insist on a careful technic of the same by the attending physician. Success in surgery is attained by thorough technic in the respective fields, and if we as physicians are to gain any exactness in our treatment we must carefully eliminate the unnecessary routine and centralize and magnify those means which we have found essential and necessary.

DISCUSSION.

Dr. John C. Cook, Chicago, emphasized the value of water in the treatment of typhoid fever. The value of washing out the toxins is unquestioned, and the water treatment in general has been proved to be valuable. When antitoxin was first introduced and was gaining ground, Baginsky was asked if it were advisable to use it in all cases. His answer was to use a remedy when it was fashionable, that it cured them. There is probably nothing that has marked the different periods of the medical era as much as our views on therapy. Everyone who has used enteroclysis as a routine treatment has undoubtedly found it valuable. In Dr. Hollopeter's experience in hopitals his nurses are trained, but in private practice where nurses are not at hand the details of this treatment should be gone into. Enteroclysis is a valuable remedy, as is calomel, but the best results will not be obtained from it unless detailed directions are given for its employment. The ice bag Dr. Cook considers a valuable remedy, but in private practice the physician can not tell those in attendance to leave the bag on the head indefinitely without some reference to the temperature.

Dr. Kate Lindsay, Boulder, Colo., said that the ice bag can be used very well in private practice if the physician applies warm fomentations for three to five minutes after the ice bag has been on for an hour or two and then gives a brisk rubbing. The ice bag can then be reapplied. This will quiet the nervous system and makes the treatment pleasant to the child. The ice bag can be applied safely by those who are very inexperienced if the details are attended to and the circulation kept up. A pleasant effect will be gained by the intermittent use of short, warm applications, and the effect of the ice bag can be prolonged by this combination of heat and cold.

Dr. A. C. Cotton, Chicago, thinks that physicians are too apt to trust details to the nurse. Many nurses supposed to have been thoroughly trained fail to recognize all the anatomic requirements. When a nurse introduces a thermometer or the nozzle of an irrigator into the rectum with the baby in the dorsal position, she is taking the chances of causing traumatism of the posterior wall of the rectum. The probabilities are that the nurse will have the child lying on its back. In irrigation of the rectum there are many opportunities for traumatizing the mucosa. Of course, the physician knows that the axis of the rectal outlet forms an angle of 40 degrees with the long axis of the body, and that no rigid instrument can be introduced into the rectum from the front with a patient in the dorsal position without forming a right angle with the posterior wall of the rectum. It is easy, therefore, to see how rectal ulcers may develop. Dr. Cotton believes in this care of the child in typhoid fever especially; since frequent invasion of the rectum may have to be kept up for perhaps three weeks, it is an essential point that the nurse be instructed to turn the child over on the side, introducing the tube at an angle of 40 degrees.

Dr. John Lovett Morse, Boston, said that in judging of the results of the treatment of typhoid fever in children it must always be remembered that the tendency of this disease in childhood is to recovery. He cautioned against forming too favorable an opinion of the results of treatment by large amounts of water internally. He does not think that the published results from this form of treatment will bear close investigation and feels sure that when others begin to try the treatment they will not obtain the same results. It should be remembered that in typhoid the vasomotor system is relaxed and that on this account care must be observed in putting large amounts of water into the relaxed vessels, and thus dilating them more and bringing further strain on the heart. In a recent case of scarlet fever treated in this way, so much water was given that dilatation of the stomach resulted, and several months were required for the recovery of the patient. Dr. Morse does not believe it is necessary to keep patients with typhoid fever on so restricted a diet as is usually done. He feels that a diet composed entirely of milk is not the best food. There is no food, in any way reasonable, which will give such a large residue as milk. A caloric value much greater than from milk can be obtained by giving diluted cream. Better than proteids and albuminoids in the diet is some form of starch sugar.

Dr. W. C. Hollopeter said that Dr. Cotton's statement relative to the danger of injury to the bowel seemed rather misleading. Dr. Hollopeter allows the tube to be inserted just beyond the external sphincter when the water is turned on; by this method the water forms a cushion which slowly dilates the bowel, and the tube following causes no injury. It would be a rude method indeed to push the tube into the bowel without first distending it. He emphasizes this point because nurses are prone to employ this valuable therapeutic measure in a slovenly manner. Dr. Hollopeter referred to Dr. Lindsay's remark about the warm application, and said that he believes we can reduce temperature as well with warm water as with cold. He never uses cold unless there is a very high temperature. In answer to a question, he said that before a physician gets a patient with typhoid fever he has his mind made up to use enteroclysis.

THE EXTRACTION OF UNCOMPLICATED IMMATURE SENILE CATARACT.[*]

ALBERT E. BULSON, Jr., M.D.
FORT WAYNE, IND.

In a discussion of this subject it is appropriate to say that a cataract is designated as senile if the patient has reached the fiftieth year of age; uncomplicated, when not associated with any special disease; and immature, when the opacity does not extend throughout the entire lens substance.

While this designation is in accord with the generally accepted teaching of to-day, technically we probably are not warranted in associating cataract with senility in the sense that the opacity of the lens occurring after middle life is a symptom of senility; or in designating a cataract as uncomplicated simply because we fail to detect the co-existence of any other intraocular pathologic condition.

Numerous observers have asserted that there are good grounds for considering eyes in which cataract develops as otherwise diseased. Thus Becker[1] states that, strictly speaking, there is no such thing as a primary cataract, the expression "primary" simply hiding our ignorance. Foerster[2] evidently recognized the influence of a previous or general disease when he said, "If a cloudiness of the lens is just beginning, very severe bodily ailment may hasten the development of cloudiness," to which Stricker[3] adds, "The constitutional disease manifests itself in its action on the lens in such a manner that it either first causes disease of other portions of the eye, thereby leading to a pathologic changed vitreous, which, in its turn, leads to a disease of the lens and cataract formation, or the lymph of the entire organism becomes changed, thus leading to cataract formation without any other disease of the eye having previously existed." Risley,[4] in calling attention to the importance of choroidal disease as a factor in the production of opacity of the crystalline lens, makes the statement that "while opacity of the lens is a disease of advanced life, it does not in all probability depend on senile change, but is originated in local pathologic states involving the nutrition of the eye itself." It is probable, however, that functional decline of the tissues of the body, which mark the onset of senility, may, by lowering the resisting power of the tissues of the eye, be responsible for the development of pathologic conditions which disturb the normal sclerosing process in the lens and lead to opacity. We may have premature, as well as delayed senility, but that does not account for the cataracts which occur in persons just past middle age who may be prematurely in decline, nor does it explain why persons of great age in whom the signs of senility are exceptionally pronounced, and who have remarkably good vision, are exempt from cataractous change of the lens. It is reasonable to presume, therefore, that cataractous change in the lens is either secondary to some disease, either local in the eye, or to some general disease of the entire organism, and that senility may or may not be a factor in the production of the pathologic state on which the development of the cataract depends.

The existence of marked choroidal and vitreous changes accompanying incipient cataract we are all familiar with, as such cases are frequently presented to us before decided clouding of the lens makes a satisfactory ophthalmoscopic view of the fundus impossible, and at a time when the vision is more impaired by the choroidal and vitreous changes than by the loss of transparency in the lens. But there is a class of cases in which a mild choroidal inflammation precedes the development of cataractous change in the lens, which may be undiagnosed unless the ophthalmoscopic examination is made early in the progress of the case, which frequently is not possible because the opportunity for such examination is not offered, or may be overlooked later, when the patient presents himself on account of failing vision from incipient cataract, unless the history of the case is carefully considered and unusual care is exercised in making the ophthalmoscopic examination with a fully dilated pupil. The fact that we do not find diseases of the eye ground after the extraction of the cataract does not indicate that such diseases did not exist in mild form at the beginning of the cataractous process, and subsequently disappeared as a result of the enforced rest of the eye occasioned by the clouded lens. From the fact that I have been able to detect these mild pathologic changes in the fundus frequently during the stage of incipiency of cataract, I am inclined to believe, as Risley has pointed out, that diseases of the eye ground are the rule rather than the exception in cataract patients.

With a recognition of the diseased processes which constitute the principal factor in the causation of cataract we may hope, by applying the proper treatment at the proper time, to prevent the occurrence of cataract in a fairly large percentage of persons who present themselves to the ophthalmologist before cataractous change in the lens has set in, or at a time when the beginning cloudiness of the lens is so slight as to make its arrest entirely possible. In those cases in which the process of cataract formation has become well established I do not believe it is possible to cause a retrogression, and it is those cases, when unaccompanied by diseased processes which would contraindicate operative procedures, with which this paper deals.

But the very fact that many, and perhaps the majority, of immature cataracts are accompanied by at least a mild disturbance in the uveal tract is sufficient ground for hesitation in attempting extraction, even in the absence of other contraindications, for the reason that enforced rest occasioned by the increasing opacity of the lens is a measure required to produce a subsidence of the uveal disturbance, and the beneficial effects of which would be more or less destroyed by extraction of the protecting lens. As the existence of those mild vitreous and choroidal inflammatory or degenerative changes must necessarily alter the prognosis in extraction of immature cataract, it is of the utmost importance that the history of such cases be given careful consideration and the functional examination of the eye be carried out with utmost care. In many cases, again to quote Risley,[5] to whom we are indebted for extensive study of this subject, a long history of asthenopia, preceding the failure of vision from incipient and immature cataract, a more or less discolored iris, sluggish in its action to light and shade, and to mydriatics, injected conjunctiva and swollen caruncles, associated with headache, furnish a group of symptoms which point to the existence of choroidal disease." These processes do not, in a large proportion of cases, present the gross ophthalmoscopic appearances which characterize the rapidly destructive diseases in which marked retino-choroidal inflammation, fluid and muddy vitreous, and floating opacities are conspicuous features, but they are attended by a characteristic group of objective symptoms which, if not demanding treatment, certainly demand the enforced rest secured by the gradual opacification of the lens. But in those slowly progressing cases in which the clouded lenses, even though semi-transparent, have practically incapacitated the individual for the ordinary pursuits of life, and in which the enforced rest of the eye ground for a greater or less period has resulted in quieting the objective symptoms present with the beginning of the cataractous process, the advisability of extraction becomes a question worthy of attention.

In considering the operative features of these cases of cloudiness of the lens in those persons beyond middle age it is essential that we differentiate the immature cataract from the loss of transparency, accompanied by impairment of vision, due to advanced sclerosis. The one is a diseased process, due to an interference with the normal sclerosing process and accompanying alteration in the transparency of the lens (Becker), whereas the other is purely a physiologic process due to a lessening of the transparency on account of the hardening of the lens and consequent greater absorption of light. In the immature cataract, particularly those occurring in persons under 50 years of age, there will generally be found a soft cortex, adding to the difficulties of extraction, whereas in the sclerosed lens the cortex will be found hard, thus making it possible to extract the lens in its entirety.

Until recent years it was the generally accepted teaching that immature cataracts were not favorable for extraction, owing to the difficulties encountered in the removal of soft cortical material, and in consequence nearly all operators followed the practice of waiting until maturity, or until the lens was entirely opaque, before attempting extraction. That policy is still followed by many experienced and competent operators, though not a few attempt, and with a considerable degree of success, to hasten the time when extraction may be performed by practicing artificial ripening of the cataract by one method or another.

Schweigger,[6] in a paper published in 1890, was one of the first to advocate the extraction of unripe cataracts, and has asserted that he does not believe that it is necessary to cause an artificial ripening after the time when physiologic changes in the lens have done away with the act of accommodation; that is, toward the fifties and surely after the sixtieth year. He operates "all patients past the fiftieth year as soon as the senile cataract interferes greatly with the patient's vision, so that life ceases to be a pleasure to him, and he becomes unable to be self-sustaining, and the doctor may hope that by removal of the lens vision may be materially improved. It is immaterial whether a greater or less portion of the lens is still clear." This teaching of Schweigger, while not generally accepted and followed, has had the tendency to give many operators confidence in their ability to secure satisfactory results from the extraction of unripe cataracts, and as a result the practice is growing more and more in favor, with its attending benefits to that large class of unfortunate persons suffering from immature cataracts who otherwise would be compelled to go without useful vision for months and perhaps years while waiting for the cataract to become "ripe," and thus best suited to extraction. (Since writing this paper, Professor Hirschberg informs me that he advocated, prior to the publication of Schweigger's paper, the extraction of immature cataract, and his views on this subject, expressed before the Berlin Medical Society, were published prior to the appearance of Schweigger's paper in 1890.)

The principal objection to the extraction of immature cataract has been that, in the attempt to remove a lens not entirely opaque, more or less of the cortex remains which adheres to the capsule and is difficult, if not impossible, to remove without subjecting the eye to trauma which later gives rise to inflammatory reaction and jeopardizes the function of the eye, and if allowed to remain will either produce secondary cataract, with attending impairment of vision, or inflammatory reaction, with danger of damage to the function of the eye, or both.

Concerning the age at which the lens is sufficiently sclerosed to permit of its complete removal from the capsule, Schweigger[6] makes the following statement: "At sixty years of age the lens is hardened in its entirety, whether cataractous or not, and whether the cataract is complete or not. The cataract and the induration are phenomena absolutely different; the one is pathologic, the other physiologic. Thus, in persons of 60 years who have lost the faculty of accommodation, a cataract even incompletely developed may be removed without the opacities being reproduced, for it is certain that the lens can be removed entirely." To this statement I think we may take exceptions. Under the fiftieth year, or while there is still some accommodation present, the cortex of the lens still consists of a tenacious sticky mass, but I have frequently observed a soft tenacious cortex after the sixtieth year, and occasionally after the seventieth year, in lenses that were the seat of immature cataractous formation. While sclerosis may have progressed to that point where in some cases at sixty years, as Schweigger says, the lens may be easily extracted in its entirety, whether cataractous or not, generally speaking we are not warranted in assuming such a conclusion for every case, and the extraction of any unripe cataract carries with it the possibility of having to contend with soft cortical substance, with the chances of a lessened amount or none with increasing age of the patient.

With a reasonable certainty that an unripe cataract, except in a person of advanced age, is accompanied by more or less soft cortex, the advisability of attempting extraction becomes a question for serious consideration. In making a decision several factors must be taken into consideration. First, what is the state of vision in the fellow eye; second, how rapidly is the cataract progressing; third, how seriously inconvenienced will the patient be if he waits for maturity; and, fourth, what contraindications are there to the extraction of the cataract, even though immature.

Those ophthalmologists who possess an unduly ambitious desire to operate on the slightest provocation, and who favor extraction of immature cataract, may advise operation, no matter if the fellow eye has approximately perfect vision; but such advice is not good and should not be accepted. No extraction of an unripe cataract is warranted when the fellow eye has vision sufficient for the patient's needs, unless the first discernible signs of beginning cataract in the fellow eye warrants the belief that the increasing opacity will soon seriously interfere with vision and it is thought that extraction of the more pronounced cataractous lens will restore good sight before the failing vision in the fellow eye has had time to reach a stage where it will seriously inconvenience the patient. Even in such instances the needs of the patient, so far as earning a living is concerned, the general physical condition, the state of the eye as concerns irritation or swollen lens, and the progress of the opacity must all be taken into account before arriving at a final decision to operate. Particularly contraindicated is the extraction of a lens swollen by imbibition, attended with shallow anterior chamber and sluggish pupil from an irritated iris; for here, in addition to the difficulties of making a proper corneal section, must be considered the probability of the existence of a quantity of particularly tenacious soft cortical substance, the manipulations for the removal of which are almost sure to set up an inflammation of more or less severe character in the already irritated iris; and, furthermore, the swelling of the lens is an indication of rapid progress of maturity which it is unquestionably advisable to await in such case.

---

[6] Extraction of Unripe Cataract, Berliner med. Gesselschaft, 1890. Hirschberg's Centralblatt.

With immature cataracts in both eyes, the advisability of operation depends on the rapidity of progress of the more advanced cataract, and the amount of inconvenience to which the patient will be subjected if maturity of the cataract is awaited. At times the ripening process proceeds very slowly, while in other instances it is rapid. The history of the case, giving approximate date of onset of failing vision, will in many cases serve to indicate the rapidity of progression, though in most instances it is advisable for the ophthalmic surgeon to determine the progress of opacification by repeated examinations during a period of from one to four months. If it is determined that the process of opacification is progressing rapidly, it certainly is advisable to await maturity of the cataract before attempting extraction, for it must be admitted that, all things considered, the chances for an easy and complete removal of the lens in its entirety, with a minimum amount of trauma and attainment of the best possible vision, are better if the cataract is mature.

In the rapidly progressing cases it is seldom that a person can not afford to wait for a reasonable amount of maturity before having extraction performed. Such patients should be made acquainted with the fact that in those rapidly progressing cases that are accompanied by swelling of the lens the difficulties of extraction are greater on account of the shallow anterior chamber and impossibility of making a proper corneal section, and the tenacious soft lens substance requires more manipulation to remove it, thus increasing the liability of postoperative inflammation. As a result of all this, with consequent slow recovery, no time is saved by having the operation early, even though the ultimate results are as satisfactory as they would be by waiting for practical maturity of the lens before consenting to extraction.

In those rapidly progressing cases in which there is no swelling of the lens and attending shallowness of the anterior chamber, the recommendation of operative interference should depend on uselessness of the other eye and extraordinary physical or mental conditions which make it advisable to hasten the recovery of vision, and in such instances I consider most persons who are unable to read Jaeger, No. 12, as proper subjects for operation.

In not a small proportion of cases the process of opacification is slow, while in some instances the cloudiness of the lens proceeds until useful vision has been lost, and then becomes practically stationary, with a portion of the lens still more or less transparent. Becker[7] describes a form of premature senile cataract in which "cloudiness develops in the nucleus between the fortieth and fiftieth year after the normal sclerosing process in the lens is far advanced. This cloudiness gradually extends into the transparent cortical substance and has a peculiar white, almost milky, color. This cataract is exceedingly slow in its development, but finally becomes a total cataract. The individuals show in their general appearance that their health has been disturbed for a long time. They are people who have been reduced by disease, excessive bodily exertion, many and difficult labors, material want, grief and care." Becker further states that, without in such cases being able to demonstrate a diseased condition of the nutritive fluids of the body, we may look on the general premature senility of the entire body as a cause of the failure to form the nucleus, which is a feature of a lens which becomes diseased in this manner.

Cortical cataracts are usually progressive, but frequently the progress is so slow that a long period intervenes between the time when cloudiness of the lens interferes with vision and the time when opacification is complete and the cataract may be said to be mature.

In these cases of slowly progressing cataracts of both eyes which may require months or even years to reach maturity, it is an unnecessary hardship to await natural maturity of the lens before adoption of measures for the restoration of vision, and a recognition of this fact led some operators to the adoption of the practice of artificial ripening of the cataract. Several methods have been recommended for hastening the process of ripening, among which may be mentioned simple division of the anterior capsule with a knife needle, iridectomy combined with some form of trituration of the lens, or paracentesis of the cornea combined with external massage.

In my own experience I have found that a preliminary iridectomy alone is usually sufficient to hasten artificial ripening of the cataract, though I doubt the propriety of generally subjecting the eye to the risks of two operations, including the preliminary iridectomy, either with or without trituration of the lens, and the subsequent extraction, when the same end may be secured with equally good results by the single operation of extraction. So far as the value of a ripening operation is concerned, I believe, as has been stated by Weeks,[8] "that the operation for hastening the maturation of the lens does not sufficiently increase the facility of removal of the cataract to warrant the extra risk and trouble to the patient."

The state of vision in slowly progressing senile cataracts of both eyes, which warrants operative interference, will vary in different individuals. In my judgment, when vision has been reduced so that ordinary type can no longer be read, both pleasure and business are suffering from the interference, and the deprivation, if long continued, usually has a more or less detrimental effect on the physical and mental condition of the individual. In such cases I do not hesitate if, aside from the semitransparency of the lenses, there are no contraindications, and the patient has been made acquainted with the possibilities as to secondary cataract requiring discission and mild postoperative inflammation, with delayed recovery. I do not expect to encounter any greater difficulty in extracting a lens that is one-third opaque than one that is two-thirds opaque, for in both instances about the same amount of manipulation of one kind or another is required to free the eye of soft lens material, and no more lens substance is apt to be left in the one case than in the other, all things being equal.

---

[7] Zur Anatomie der Gesunden und Kranken Linse, 1883.
[8] THE JOURNAL A. M. A., Dec. 15, 1900.

The difficulties attending removal of the lens in its entirety have deterred many operators from attempting extraction of unripe cataracts, for no operator from choice will face certain dangers of iritis and secondary cataract which invariably follow if any considerable amount of soft lens substance is left in the eye; and every operator knows that efforts to tease out the cortical remains alone carry with them the possibilities of trauma, which may provoke irritation or possibly result in rupture of the zonule and loss of vitreous.

Successful results from the extraction of immature cataract must, therefore, come from the adoption of methods which make it possible to remove, at the time of operation, practically all the cortex, with a minimum amount of trauma and subsequent inflammatory reaction, and the employment of such postoperative treatment as will tend to limit the effects of inflammatory reaction and promote resorption of any retained cortical substance. In my judgment the operative essentials to bring about the result are: First, a large corneal section, embracing not less than two-fifths of the corneal circumference; second, an iridectomy with a fairly large coloboma extending to the ciliary border; third, a large opening in the capsule by two incisions at right angles to each other; fourth, gentle irrigation of the anterior chamber with a sterile normal salt solution, after the extraction of the nucleus, if much cortex remains; fifth, the early and free use of atropin, and, sixth, the use of dionin, after the corneal wound has closed, to promote resorption of lens débris.

The advantages of a large corneal section are embraced in the ease with which the hard nucleus is removed without undue manipulation of the eyeball, and the increased certainty with which the irrigating fluid and soft cortical material pass out without provoking irritation from damming up in the anterior chamber.

The coloboma from the iridectomy not only facilitates removal of the soft cortical substance by furnishing a sluice-way for its escape and averts secondary iris prolapse, but tends to prevent the development of postoperative glaucoma.

The reason for the large opening in the capsule is obvious, for, with an insufficient opening, which may not be enlarged by the escaping small hard nucleus, the collapsing capsule may retain within its folds considerable quantities of lens substance which it would be difficult to remove. These enclosed masses of lens substance when cut off from the aqueous by collapse of the capsule are not resorbed, but remain to form a white membranous cloudiness or secondary cataract. If the opening in the capsule is sufficiently large, the cortex remaining after the extraction of the nucleus, even when in considerable amount, will swell up and become resorbed. This swelling of the retained cortical substance, however, with the production of an iritis, which even the liberal use of atropin does not always control, is one of the complications which we should make an attempt to avoid, and indicates the necessity for the adoption of more effective means for the removal of the soft cortical substance at the time of the extraction than is accomplished by stroking and other manipulations ordinarily employed.

The most effective means for removing the cortical remains is irrigation of the anterior chamber. Several methods have been advocated, but the one preferred is that of Lippincott, in which a continuous stream is allowed to flow by gravity through a small specially constructed canula, into the anterior chamber, the force of the stream being properly regulated by the height at which the reservoir is held, and the flow being entirely under the control of the operator, who may stop or start the stream by the use of a suitable lever. To avoid trauma, only the tip of the canula should lie between the lips of the corneal wound, and the stream should have only such force as is given it by elevating the reservoir no higher than is necessary to establish a continuous current by gravity.

Until recently I have also used with great satisfaction the method advocated by Dr. Flemming Carrow, in which the anterior chamber is irrigated with a stream from a wash bottle designed something like an ordinary bulb atomizer and having a specially constructed tip for irrigation purposes. While excellent results may be secured with this apparatus when properly employed, the objections to it are that unless the operator employs unusual delicacy and steady pressure on the rubber bulb, the stream is apt to possess too much force, with consequent trauma to the tissues. Also, unless due care is observed, air is likely to be forced into the anterior chamber, and the bubbling, with its unpleasant sensations, cause the patient to make some unexpected move which may prove disastrous. The originator of the device, who has had a very large and very successful experience in cataract extraction, does not direct the stream directly into the anterior chamber, but allows it to flow across the lips of the corneal wound, thus creating a very gentle but continuous current through the anterior chamber, with the result that the bulk of the soft cortical lens substance is carried out.

Those who practice irrigation of the anterior chamber vary in their preference as to the solution to be used. Sterile water, boric-acid solution and physiologic salt solution are about equally employed. In my own practice physiologic salt solution is preferred as being less likely to produce irritation from its own qualities.

Irrigation, if it is to be accompanied by a minimum amount of irritation and yet be effective, should be carried out with the utmost delicacy. The stream should be continuous, but possess no more force than that obtained by gravity when the reservoir is just high enough to create a current; and less trauma is likely to result if the current is directed into the anterior chamber on a line with the corneal section. Prolonged irrigation should also be avoided, as it is entirely unnecessary and is apt to be attended with increased trauma. If the capsular opening is large, it is seldom that the bulk of the soft cortical substance is not removed, but, if not removed, prolonged irrigation is not warranted, as much of the remaining lens substance will be resorbed by the action of the aqueous, and if not resorbed had better be subsequently divided by a discission operation rather than removed by prolonged irrigation or other manipulations which increase the possibilities of trauma and resulting serious inflammatory reaction.

It must be admitted that, in spite of proper care exercised in the performance of this procedure, in nearly all of the cases more or less iritis is the rule rather than the exception. This is due to the slight trauma necessarily following the irrigation and the irritation produced by the swelling of the remaining soft lens substance. In the majority of instances this iritis produces no serious consequences if atropin is used early and continued until all signs of irritation have disappeared. In many cases the irritation of the iris is no more than accompanies the extraction of mature cataract, but it is well to anticipate it and to adopt the proper medical measures early in the progress of the case. It has become my practice to anticipate such trouble by using atropin at the time of the first dressing, 36 to 48 hours after the extraction.

A remedy that I have found of decided service in promoting resorption of lens débris following cataract extraction is dionin. This drug, as has been pointed out by Darier,[9] possesses decided lymphagogue properties, and further experience in its use to promote resorption of cortical remains warrants me in reiterating a statement which I have previously made[10] that "the remarkable results secured by dionin in clearing the pupillary space following cataract extraction has led to the belief that, with the more or less general employment of this drug, after cataract extraction, secondary operations will be lessened in number." It should be remembered, however, that some persons apparently do not react to dionin, and in such I have not been able to detect any favorable action in promoting resorption of lens débris, but it may be said in its favor that if it produced no favorable action it certainly has produced no unfavorable results.

Until the susceptibility of the patient to dionin has been determined it is best to begin with a 5 per cent. aqueous solution, and, owing to the active smarting produced, it is advisable to precede the application with an installation of cocain. Owing to the smarting, with involuntary tight closing of the eyelids, with attending pressure on the eyeball and the sneezing that is occasionally induced, it is also advisable to use dionin only after the corneal wound has been securely closed for a period of from five to seven days.

In susceptible persons dionin produces marked vascular injection, with edema and extravasation of lymph, and in my experience the more marked the reaction in this respect the more marked is the favorable action in promoting resorption of lens débris; in fact, the strength of the solution is increased to 10 per cent., or the pure powder is used, in an endeavor to produce such reaction in those who do not apparently respond to the usual effect of the drug. Unless there is decided reaction the applications are repeated from two to four times per day for a period of four days, at the end of which time a certain tolerance is established and no further beneficial effects may be expected until an interval of at least a week has elapsed. While there are a few cases in which this remedy seems to have no appreciable effect in promoting resorption of the cortical remains, in a larger number of cases the results secured in effecting a clearing of the pupillary space, even where a considerable quantity of cortical lens substance has remained, have been so strikingly favorable that I feel warranted in unhesitatingly recommending the employment of this measure as a routine practice after all cataract extractions. I am still further influenced in giving this recommendation because of the fact that dionin has a marked favorable action in the treatment of iritis, in promoting the absorption of exudates and increasing the effect of atropin; and, as iritis accompanying swelling cortical lens remains follows cataract extraction, there is double reason for the employment of dionin.

The extraction of immature senile cataract may be attended with more complications and less favorable immediate results than the extraction of mature cataract, but the final results, when the cases are properly handled, should compare favorably with the extraction of cataract in any stage. In the extraction of immature senile cataract in persons of any age I have learned to expect a certain amount of soft lens substance, but with a large opening in the capsule and the employment of irrigation the greater portion of the lens débris is removed, and what is not removed is generally resorbed either with or without the assistance of the action of dionin. Discissions, while necessary in a fair proportion of cases, are not, in my experience, so frequently required as formerly or before dionin came into favor as an agent to promote resorption of lens débris. Iritis, frequently seen, either produced by trauma at the time of the operation or subsequently by the action of the swelling lens substance remaining, is controlled by the early and free use of atropin.

Admitting that the immediate results from the extraction of immature senile cataract are not as good as in the extraction of mature senile cataract, on account of the greater possibility of having to contend with iritis and secondary cataract, it is nevertheless a fact that the ultimate results are equally as good, and this opinion is attested by many of the most prominent operators of the United States, whose views on this subject are appended to this paper. That the complications arising are no greater than those accompanying the extraction of hypermature cataracts, which form a considerable portion of the number of cataracts presented to the average operator for extraction, is also accepted as a fact, for in both classes of cases the development of an iritis and the formation of a secondary cataract are the rule rather than the exception. The slow recovery in a few cases, due to inflammatory reaction directly dependent on the effects of the operative procedures, while seemingly indicating that the operation has not been to the best interests of the patient, are not generally detrimental to the extent usually supposed; for under such measures as herein advocated the iritis usually completely subsides in from two to six weeks, soon after which, if required, the discission operation may be performed. Even with more protracted recovery the patient is usually favored with the restoration of vision much sooner than could possibly be expected had maturity of the cataract been awaited, and this at a time when the general health has not been impaired by the enforced inactivity and the mental disquietude occasioned by a prolonged period of waiting for complete opacification of the lens before extraction.

My personal experience in the extraction of immature senile cataract, while not large, has been very satisfactory. During the past four years, or the period during which I have followed the practice, I have extracted twenty-five more or less unripe senile lenses, and ten of the number have been operated on within the past fourteen months. In all the cases the ultimate vision has compared favorably with the vision obtained in the cases of mature cataract operated on either during the same period or before. In eight cases the vision was 20/20; in ten, 20/30; in two, 20/40; in three, 20/70, and in two, 20/200. Nine of the cases required secondary operations, and six should have had secondary operations, but for one reason or another did not have them. In all but two of the cases in which vision was under 20/20, there was secondary cataract, and, as some of those were lost sight of soon after the operation, it is possible that vision improved in course of time as a result of resorption of a greater amount of the lens débris. A striking feature of the eight cases having 20/20 vision was the fact that but three had a secondary operation, and the remaining five, which soon after the extraction gave evidence of requiring a secondary operation, obtained excellent results under the effect of dionin. Three of the latter cases were under 60, and one but a little over 50 years of age. Practically all of the cases had irrigation of the anterior chamber and few escaped at least a mild iritis, though the inflammatory action had nothing to do with the failure to secure good vision in any of the cases. All of the cases had the combined operation. In only three cases was preliminary iridectomy performed, and in all three, following the extraction, a subsequent operation for secondary cataract was required. All of the cases were what would be called uncomplicated, in that they had no marked choroidal or vitreous changes, swelling of the lens, or external evidences of disease. In all of the cases vision had been reduced below the patient's requirements.

---

[9] Ocular Therapeutics, 1903.

[10] Ophthalmic Record, August, 1904.

With a view of obtaining information from other operators as to the practice of extracting immature senile cataract, the following inquiry was sent to a large number of prominent ophthalmologists: (A) Do you extract uncomplicated immature senile cataracts? If so, what is your rule as to (1) Age of patient? (2) State of vision of eye to be operated on? (3) State of vision of fellow eye? (4) Form of operation to be performed, simple or combined, or preliminary iridectomy and extraction later? (5) Irrigation of anterior chamber, and, if employed, what solution used? (6) Use of dionin to promote resorption of débris? (B) Generally speaking, what have been your results in extracting uncomplicated immature senile cataracts as compared to extraction of uncomplicated mature senile cataracts: (1) As to vision obtained? (2) As to development of secondary cataract requiring operation? (3) As to inflammatory reaction from operation? (C) What difficulties have you encountered in extracting immature senile cataracts? (D) What objection, if any, have you to extraction of immature senile cataracts?

While some of the questions were not answered even in a general way and others were answered in such manner as to admit of no definite interpretation, I find by analyzing the reports containing specific answers that out of 65 who responded, 25 have no hesitation in attempting extraction of uncomplicated immature senile cataract, 22 perform the operation with some hesitancy but apparently not from choice, 9 have serious objections to the practice, but in certain apparently urgent conditions take what they term the "risk" of the operation, and 8 do not extract immature senile cataracts at all, because they consider the final results bad in the majority of instances.

All who operate have as a condition of the operation that the eye to be operated shall have sufficient failure of vision to interfere seriously with the pleasures and pursuits of the patient, and an equal failure or complete loss of vision in the fellow-eye. In no instance is an operation advocated when there is vision in the better eye sufficient for the patient's needs.

In considering the advisability of operating, 32 do not consider the age, 3 place the age limit at 40 years, 3 at 50 years, 6 at 55 years, and 7 at 60 years. In nearly all instances, the form of operation selected is reported as varying with conditions presented, but the first choice is given as preliminary iridectomy by 27, combined operation by 18, and simple extraction by 10. Some say, and presumably all intend to convey the idea, that preliminary iridectomy is performed with the idea of artificially hastening the opacification of the lens before extraction. In a few instances mention is made of trituration of the lens at the time the preliminary iridectomy is performed.

Thirty practice irrigation as a routine measure or reserve it for those cases in which the soft lens substance does not come away easily by usual manipulations, and with four exceptions physiologic salt solution is the solution preferred.

Nineteen use dionin to promote resorption of lens débris, and out of this number nine report good results, the others reporting doubtful results or not referring to effect.

While nearly all report that secondary cataracts and mild postoperative inflammations, with slow recovery, are more frequent than in extraction of mature cataracts, they almost without exception report as favorable ultimate visual results as in mature cases.

It is quite possible that with an improved technic, including many if not all of the essentials herein advocated, that the development of secondary cataracts and postoperative inflammations will be reduced to the point where they will not occur more often than after extraction of mature cataracts. But even if this were so, the results obtained by the operators herein reported, as well as by myself, warrant me in recommending the extraction of uncomplicated immature senile cataract, irrespective of age, in all those persons who, on account of the clouding of the lens, have vision reduced to such a degree that the individual can not follow the ordinary vocations of life.

OPINIONS OF PROMINENT OPERATORS ON EXTRACTION OF UNCOMPLICATED IMMATURE SENILE CATARACT.

Herman Knapp, New York City: Yes. Uncomplicated, unripe cataracts can be operated on with a good prospect of success when the general and ocular conditions are favorable and a large corneal section can be made.

F. C. Hotz, Chicago: The question of extraction of unripe cataract can arise only if the vision of both eyes is so much impaired that the patient can not attend to his business any longer. As long as he enjoys fair vision in one eye, the operation is not warranted. If both eyes are affected I am guided by the condition of the lens whether to operate immediately. If the cataract presents an opaque nucleus enveloped in a cortex which, though not completely opaque, is sufficiently so that the pupil shows only a faint red reflex, I operate, and I find these cases yield generally as good results as the perfectly mature cataracts. But if the cortex shows sections of almost perfect transparency, I do not regard extraction advisable, because the transparent substance can not be gotten out cleanly, even by irrigation, and its subsequent swelling causes complications in the healing, iritis and dense secondary cataract. As in these lenses, the opacification usually progresses rapidly, I think it is wiser to let the patient wait a few months than to take any chances. But should the patient insist on having something done at once, I perform a preliminary iridectomy, and massage the lens to hasten the process of opacification. On the other hand, there is a kind of immature cataract, and I see them often, which I extract without hesitation, though the vision may be 20/100 or better and the ophthalmoscope shows good red reflex. These lenses show a rather uniform diffuse haziness without distinct nucleus, vary little in the course of a year, and never become completely opaque. When extracted, they come out as one semi-translucent yellow cake; there is no cleansing necessary; the pupil appears perfectly clear and black; and the results are excellent; in fact, I am almost inclined to say better than after extraction of the ordinary mature cataract.

John E. Weeks, New York City: Yes. In persons more than 55 years as a rule, who are unable to read ordinary primer type with the eye to be operated on and vision in fellow eye is lost or reduced so that the patient is unable to follow vocation. Preliminary iridectomy performed in many cases, combined operation in some, simple operation in a few. Irrigation with normal saline solution if any cortical lens substance remains. Results as compared with mature cases, very little difference. Degree of vision, taking all cases, perhaps a little less. Maximum vision not reached so soon. Vision 20/20 in about 30 per cent. of the cases. Secondary cataracts more frequent than in extraction of uncomplicated mature cataracts. Seldom have subsequent inflammatory reaction. Cortex more adherent to capsule than in mature, but not more so than in hypermature. If lens is shrunken, nucleus amber colored, anterior chamber as deep or deeper than normal, I do not hesitate to operate. If lens is large, asbestos striped and anterior chamber shallow, I hesitate to operate. Maturity does not always mean complete opacification of the lens substance. I b[illegible] ·ipening operation for the reason that the [illegible] s not sufficiently increased to warrant the [illegible] to the patient. Whenever in the development of cataract the vision is reduced to such a degree that the individual can not follow the ordinary vocation of life, provided there is any reason for not waiting until the cataract is matured, I do not hesitate to advise operation.

G. E. de Schweinitz, Philadelphia: I may say in general terms that I very frequently extract immature cataract, but that I do not extract it if the lens is in the stage of swelling, which I believe to be distinctly a contraindication, especially if associated with the swelling there is much shallowing of the anterior chamber. I do not believe that it is at all necessary to watch for what we used to call full maturity, especially if the patient is past the age of 55 or 60. I always make an iridectomy if I extract an unripe cataract, and preferably a preliminary iridectomy, which I believe to be far the safest way of dealing with these cases. I do not know how many unripe cataracts I have extracted, but the number is large. I have never had a serious disaster, although I have been obliged on some occasions to make more than one discission subsequently to get rid of cortical remnants. My experience with washing out the anterior chamber is a very limited one, as at one time I was very positive that it was a bad procedure. I have begun to change my views, however, since seeing some very excellent results in the hands of some of my friends, and I think that hereafter, should I meet with cases in which it was difficult to remove remnants in extractions of unripe cataracts, I would certainly use irrigation. In general terms, I would say that my operations for extracting unripe cataracts have been quite as good as those which I obtained after extracting ripe cataract, although the procedure has been more trouble in some instances. I believe it is better to extract an unripe cataract than it is to do a ripening operation.

Charles H. May, New York City: Yes, in persons of any age if the vision in each eye is sufficiently reduced to interfere with the patient's usual occupation. The combined operation is generally preferred, but if the cataract occurs in an individual in whom the other eye is blind, preliminary iridectomy is performed. Irrigation with physiologic saline solution is employed if cortex is left. Dionin not used. Results compare very favorably in the end with results in extraction of mature cataracts. Secondary cataract relatively more frequent, and as a rule rather more inflammatory reaction. No special difficulties encountered in extraction of immature cataract and no objections to the practice.

Edward Jackson, Denver: Yes, in persons of any age if the case presents the visual need, i. e., vision in each eye reduced so as to interfere with patient's usual occupation. The simple operation preferred, but in certain cases the combined. Irrigation rarely employed, but when used, physiologic salt or boric-acid solutions preferred. Have not tried dionin. Results as satisfactory as in extraction of mature cataract and equally good vision ultimately. Secondary cataract more frequent, but by no means constant. No greater inflammatory reaction. Difficulties encountered are those connected with removal of cortex. My only objection to extraction of immature senile cataract is that the immediate result is not so good. This does not deter me from operating in suitable cases.

Charles H. Williams, Boston: Yes, in persons of any age having good or fair general health when vision in eye to be operated on is less than 1/10, and vision of fellow eye is reduced so that the patient can not do necessary work. Simple extraction preferred. Employ irrigation with one-half of 1 per cent. salt solution if much cortex is left. Do not use dionin. Results about the same as in extraction of mature cataract. Results sometime depend more on the general health and disposition of the patient than on the question of maturity of the cataract. Secondary cataract occurs more frequently than in mature cataract. Inflammatory reaction perhaps a little more frequent. Ultimate results as good as in extraction of mature cataracts.

H. D. Bruns, New Orleans: I sometimes extract immature cataracts in persons of any age if there are no contraindications in the general health of the patient or the condition of the eye to be operated on. State of vision must be inability to read ordinary print with eye to be operated on and an equal disability in fellow eye. Operation preferred depends on circumstances. Unless there is some reason in the disposition of the patient, or unfavorable local conditions (rigidity of pupil, elevated tension, corneal opacities, etc., etc.), I always do simple extraction. If the section has been too small, iris does not reduce well, and is bruised by manipulation, much cortex is left behind, or much opaque capsule, patient restless and causing prolapse after one or two successful reductions, I at once proceed to do iridectomy. If at end of forty to forty-eight hours, when dressing is removed for first time, there is prolapse, I do iridectomy then. All these reasons, circumstances and conditions incline me to iridectomy much more in case of immature than mature cataracts. I use irrigation sometimes, but prefer to do without it, and without anything that increases the amount of trauma and the number of instruments introduced into the eye. I do not use dionin. Results are practically the same as in mature cases. Have seen no striking difference in the ultimate vision. Nearly always there is denser secondary cataract, and usually more inflammatory reaction, owing to greater traumatism in getting away cortex and denser contracting secondary cataract. Difficulties encountered are those connected with removal of cortical lens substance left behind when nucleus delivered. I have no objection to the practice if indicated, i. e., patient so blind in both eyes as to be unable to read or amuse himself with near-work. So long as the patient can read and write and pursue ordinary vocation with one eye I decline to do any extraction in senile cataract. Patient often dies before operation is necessary. Cataract extraction is surely a major operation. The shock is more than it seems the patient or we anticipate. I am convinced that it often hastens [illegible] ·ath of old people. Slight immaturity I [illegible] ·en patient has but one eye I always do [illegible] whether cataract is mature or not. In such cases I would wait for a greater degree of maturity than where the patient had both eyes operable, as the patient should have the best possible chances for the restoration of vision in his only eye.

Vard H. Hulen, San Francisco: Yes, in persons of any age. No rule, but prefer older patients. Vision of patient must be so poor in each eye as to interfere with ordinary pursuits, and cataracts of very slow maturation. Prefer the combined operation, but sometimes do simple extraction. Practice irrigation of the anterior chamber with normal saline solution if much lens matter remains. I have not tried dionin. Results about the same as in extraction of mature cataract and equally good vision. Secondary operations more often necessary than following extraction of mature cataracts, and expect inflammatory reaction more often. No special difficulties encountered, but more manipulation required in removing soft lens substance. Have no objections to the practice when patient's sight is so reduced as to incapacitate individual.

Frank C. Todd, Minneapolis: I frequently extract immature cataracts, and am not governed so much by the age of the patient as by other conditions; i. e., the slow progress, with poor vision in the fellow eye. When the vision interferes with going about, or in a younger patient who would otherwise be able to follow some vocation, I extract immature cataracts or do a trituration, providing the vision in the fellow eye is poor enough to interfere with going about or with occupation. I prefer, as a rule, the combined operation, or preliminary iridectomy with trituration, and extraction later. I have had no experience with either irrigation of the anterior chamber or the use of dionin. As compared to the extraction of mature cataract, my results have been equally as good There are a large percentage of secondary cataracts, except when trituration has been performed. The inflammatory reaction is not more than after the extraction of mature cataracts, though atropin should be used for a longer period or until the soft matter has had time for absorption. In general, I would say where a cataract has made good progress in ripening, I wait until it is mature or nearly mature: but when progress is slow and the patient is incapacitated by poor vision in both eyes, I extract the one that is most mature, and in case it is very immature and very slow in maturing I do a trituration. I am aware of the fact that this operation of trituration is frowned on by many, but I am convinced that it has its place, and I am further convinced that it makes a difference as to how the operation is done. When properly done it is better than to extract a very immature cataract, and after extracting an artificially ripened cataract I have never had to do a needling or secondary cataract operation.

J. A. White, Richmond, Va.: Yes, but only in cases of very slow development. No rule as to age of patient. I never operate as long as patient has good vision in one eye, but when vision is no longer useful in either eye, and the cataracts have been long developing, I operate whether they are mature or immature. Prefer preliminary iridectomy, or iridectomy at the time of extraction. Sometimes use irrigation with normal salt solution. Have never tried dionin. Results nearly the same as in extraction of a mature cataract, and vision secured practically the same. Secondary cataract or cloudy capsule is more frequent, and iritis more common. No difficulties encountered, except that the cortex is more sticky, especially under 60 years of age, and is harder to remove. Do not object to extraction of immature cataract if the other eye is failing rapidly, otherwise prefer to wait. I sometimes, however, under 60 years of age, hasten maturity by triturating the lens. I have removed about 600 senile cataracts, and among them a number of immature ones, but can not say exactly how many.

William Zentmayer, Philadelphia: Yes. Age not a factor. Am guided by circumstances of the patient as to vision at time of operation. If necessary to earn a livelihood, would operate as soon as the patient is incapacitated for that work. If independent, would advise him to await maturity. Prefer either combined operation, or preliminary iridectomy and extraction later, dependi[illegible] on the amount of unripe cortex. Irrigation [illegible] ber with physiologic salt solution employed [illegible] invariably. Dionin used to promote absorption of debris. Results, so far as vision is concerned, about as good as in mature cataract. Secondary cataracts more frequent and inflammatory reaction more marked. The difficulties encountered are principally those connected with removal of the soft cortical matter. The objection to extraction of immature cataract is that it does not afford the patient the best condition for a successful result, for the reason that the eye is usually subjected to a larger number of operations with attending risks.

Swan M. Burnett, Washington: I prefer not to operate on an immature cataract, as I think the risk is greater, but if both eyes are affected and total blindness in both eyes is near, I take the chances to gain one eye for use. I seldom do an iridectomy for any kind of extraction, and have not tried irrigation of the anterior chamber. I have had some experience with the use of dionin to promote resorption of débris following cataract extraction and am pleased with the results. As compared to extraction of mature cataract, the chances for success are not so great, and the healing process is longer, with greater liability to complicating inflammation. My objection to the extraction of immature senile cataract is, therefore, the greater danger from postoperative complications.

Leartus Connor, Detroit: Yes. Age is not considered a factor, only the reparative power. Vision must be useless for any work. Prefer preliminary iridectomy and extraction later, though sometimes do the combined operation. Irrigation with weak boracic-acid solution sometimes [illegible] in used to promote resorption of any lens [illegible] ults not greatly different than in mature [illegible] cataract not much more frequent, but sligh[illegible] reaction. There is nearly always greater difficulty in removal of all clear lens. The objection to extraction of immature senile cataract is that it is impossible to know when all of the cortical matter has been removed, and unless removed there is apt to be greater reaction and perhaps the development of secondary cataract requiring further operative attention. This does not deter me from operating in suitable cases.

F. B. Eaton, San Francisco: I have records of the extraction of a number of traumatic cataracts in patients 40 and above, in which the conditions were about the same as in an immature senile cataract, and the *principle of treatment* essentially the same. The combined operation was performed, with irrigation of the anterior chamber with normal salt solution for the removal of soft cortical material. For irrigation, I have used a device of my own, consisting of a piece of small glass tubing with soft rubber bulb at the end, the nozzle being appropriately tapered. I irrigate the anterior chamber freely, or until the pupil is perfectly black. I have never had a bad result which I thought could be attributed to the irrigation, and this is probably because the nozzle is so large that it produces a gaping of the wound, thus preventing the pressure of the fluid in the anterior chamber. I have not tried the use of dionin, but believe it indicated in certain cases. My objection to the extraction of immature cataract is that there is increased risk from inflammatory reaction and secondary cataract.

William H. Wilder, Chicago: Yes. Age is not a consideration. Vision must be so low as to prevent following occupation. Usually perform preliminary iridectomy, but sometimes the combined operation. Rarely use irrigation of the anterior chamber. Have used dionin to promote absorption of débris, and consider it entirely proper. *Results not quite so satisfactory as in mature cases*, for not so good vision recovered and usually a secondary operation is necessary. Iritis is also more common as a result of swelling cortical remains. The cortex comes away with difficulty, and what is left is not always readily absorbed. I would not hesitate to operate on immature cataract if the sight of both eyes is affected to the degree of helplessness. If the patient has one good eye I should advise waiting for the cataract to mature, or become *nearly mature, and would content myself with a preliminary iridectomy.*

C. R. Holmes, Cincinnati: Yes, in persons over 40, having vision 50 per cent. or less in both eyes, or 50 per cent. in the one eye, the other being blind or at least useless. Prefer combined operation, or preliminary iridectomy and extraction later in certain cases. I do not use irrigation, and have not tried dionin. Final results as satisfactory and vision as good as in extraction of mature *cataract, though secondary cataracts requiring operation are more* frequent, and there is usually slightly more postoperative inflammatory reaction. Have encountered no [illegible], but there is more soft cortical substance to be removed than in a mature cataract. Do not object to performing the operation in proper cases.

W. C. Posey, Philadelphia: I believe that immaturity of a lens is no contraindication for its extraction, my rule being to remove the *ripest lens in all* cases of cataract, irrespective of age, as soon as vision is so low in the best eye that the patient is unable to get about or perform the ordinary duties of life—in other words, when the test-cards show the vision in the best eye to be reduced to about 3/60. Under such circumstances I do one of three things, according to the circumstances of each case: First, a ripening operation; second, a preliminary iridectomy; third, extraction with iridectomy. If the most affected lens is very unripe, I open the anterior chamber and triturate the anterior capsule of the lens directly, removing the lens at the expiration of a few days or several weeks, according to the effect of the operation in ripening the lens. If there is no need for haste, preliminary iridectomy is done, it being found that the performance of this operation frequently aids in the ripening process as well as facilitating in the removal of the lens later. If a ripening operation or a preliminary iridectomy is not indicated, the lens is removed by the combined operation, the simple operation being reserved for mature cases only. After the removal of an immature lens the anterior chamber is frequently irrigated with a McKeown irrigator. Dionin in the strength of 4 to 8 per cent. has been found of value in promoting absorption of the débris, and has been used in many cases during the past year. I am convinced that my results in operating on immature cataracts in the manner described have been fully as good as those on mature lenses. I should say that fully 80 per cent. of the cases obtained practically full visual acuity, but I think a discission for secondary cataract was required in at least 70 per cent. of the cases. Inflammatory reaction has followed the operation in many instances, but not oftener I should say than after the removal of a mature lens. I know of no difficulties or objections to the removal of an immature lens. If possible, I think it best to avoid operating in the stage of greatest swelling, as in such cases the cortex shows a greater tendency to adhere to the capsule than when the cataract has proceeded further toward maturity.

E. E. Holt, Portland, Maine: Yes, in persons above 50 years whose vision has been so reduced that they are unable to count fingers. Formerly I did a preliminary iridectomy or the combined operation, but now do simple extraction. Irrigation used when thought necessary for the removal of soft cortical material, and dionin also used to promote resorption of any lens substance remaining. Final results good and vision not different than following extraction of mature cataracts. Do not believe that there have been any more secondary cataracts, or that I have had more secondary reaction than occurs with mature cases. In some instances the lens was more difficult to start out of the capsule. I have no serious objections [illegible]ature senile cataract, and am willing to [illegible] the patient when it is made after due [illegible] I do not remember of a single instan[illegible] or I regret that the operation was performed.

Robert L. Randolph, Baltimore: Yes, in persons over 60 who have loss of reading power. Perform combined operation always, and some of my best results followed preliminary iridectomy. Do not use irrigation or dionin. Ultimate results satisfactory; in fact, I do not recall a failure. Final vision about the same as in extraction of mature cataract. In nearly every case there was secondary cataract *requiring discission, and a mild iritis in every* case. I do not object to performing the operation in such cases as mentioned.

S. D. Risley, Philadelphia: I believe that while opacity of the lens is a disease of advanced life, it does not in all probability depend on senile change, but is originated in local pathologic states involving the nutrition of the eye itself; that hence in the stage of incipiency it is amenabl[illegible] measures as are calculated to remove the [illegible]hich it depends; that if treatment fails to [illegible] degeneration in the lens, by virtue of the [illegible] eye will be in a better condition to submit to the trials of operative interference. I never attempt extraction by the simple method in a dark gray or amber-colored homogenic lens that has ripened slowly, or on one that is translucent. In such cases secondary capsulotomies are almost invariably required, and there is a tendency to an inflammatory reaction from the slight traumatism. In these cases a preliminary iridectomy is performed, and from four to six weeks later the extraction. If after delivery masses of gray cortex remain, either free or adhering to the *capsule, their removal by irrigation* by a sufficien[illegible]alt solution is preferable to the [illegible]rable rough manipulation for its [illegible] are almost without exception required in these cases. If inflammatory reaction follow without evidence of infection, the great liability to local manifestations in those of rheumatic or gouty diathesis should be borne in mind as indicating the general therapeutic measures to be adopted. *The value of salicylic acid in these cases I* have many times seen demonstrated.

Flemming Carrow, Detroit: Yes, in persons of any age when reduction in vision prevents transaction of ordinary business. Do the combined operation in nearly every case. I always irrigate with a device of my own, using saturated solution of boracic acid, whenever any lens substance is left in the anterior chamber. I do not use dionin. Results as satisfactory and vision secured is as *good as in extraction of mature cataract. About 50 per cent. of* the cases require a discission of secondary cataract, and the same percentage of cases have postoperative inflammation. I do not object in the least to extraction of immature cataract under conditions mentioned. I am forced to express the opinion that any method of irrigating the anterior chamber after cataract extraction is productive of iritis unless used in the most delicate manner. This I state with great positiveness; but with a lot of lens débris *left in the anterior chamber which can not be removed by spoon*, stroking the cornea or any other maniplation, irrigation seems the best procedure for accomplishing the desired result. This applies to cases of hypermature cataract as well as those which are immature. I know that I am stating it properly when I say that the results are just as good if the senile cataract is removed while the patient is still able to read Jaeger No. 14 or Snellin 20/200. A man with this vision is practically put out of business, and *there is no use waiting.* This is not stated on the experience of ten or twenty cases, but on hundreds. I not only operate on these cases now and then, but it is my rule. I have operated on fourteen cases recently, eleven of which were immature, and the results were better in the immature cases than in the three which were mature. I do, however, expect a little postoperative iritis, which is probably due to irrigation of the anterior chamber. This, however, does not interfere with good results if atropin is early and *persistently* used.

M. H. Post, St. Louis: Yes, in persons of any age when cataracts reduce vision so that magazine type can not be read. Combined operation preferred. I do not irrigate the anterior chamber, and have not tried dionin. Ultimate results as good as in extraction of [illegible] experience secondary cataracts are no mor[illegible]ure cases, though there is possibly a little [illegible]ction. No objections to the operation if [illegible] *interference.*

J. M. Ray, Louisville: Yes. Age not considered if patient is in good general health. Would operate as soon as the patient is unable to follow vocati[illegible]on performed, but sometimes a preliminary [illegible] with normal saline solution when necessa[illegible] of soft lens substance. Dionin not used in this class of cases. No greater reaction than in mature. No difficulties beyond leaving too much soft lens substance in the *anterior chamber which takes a long time to absorb*, but which does absorb without trouble in time. Prefer to have an opaque lens, but have no great objection, in suitable cases, to removal of a semitransparent lens.

Alvin A. Hubbell, Buffalo: Yes, in persons over 55, with vision in eye to be operated on 10/60 and vision in fellow eye nearly as poor. Usually perform preliminary iridectomy, followed by extraction later. Employ irrigation when there is much soft cortex, using *sterile normal salt solution* and Lippincott irrigator. Do not use dionin. Results much the same as in mature cases with vision good in fellow eye never operate on the cataract. Prefer more frequent, and a little more reaction in a small proportion of cases. No particular objection to the practice. There is a little more danger of iritis.

G. C. Savage, Nashville: Yes, and regardless of age, other conditions being favorable, when vision is too low to be useful. When *vision good in fellow eye never operate on the cataract. Prefer* combined operation. I never irrigate and I never use dionin in this class of cases. Results just as good as in mature cases with vision from 20/50 to 20/20, greater number about 20/30 finally. In nearly all cases I do a secondary operation in from one to twelve months. Only occasionally is there any reaction. Have lost only one eye from secondary operation. Have no objection whatever to practice of extraction of immature cataract.

J. H. Claiborne, New York City: Yes, age not considered, provided patient in good condition. Vision in eye to be operated on, fingers at 1 foot to 20 feet. Vision in other eye not useful. Combined operation performed. As a rule, do not use irrigation, but when employed use boric acid or normal saline. Do not use dionin. Results not quite so good as in mature cases. Useful vision, but not so good as in mature cases. Secondary cataracts in nearly all cases, but no more reaction than usual in any extraction. *More difficulty in removal of the cortex that remains.* Prefer to wait unless the patient is impatient or the conditions of his life demand extraction. Best results are obtained in sclerosed immature cataracts.

C. A. Veasey, Philadelphia: Yes, in persons over 55 years of age approximately, if patient is in good health, and when vision in eye to be operated is reduced so as to make it difficult for patient to get around, and there is advancing opacity of lens in fellow eye. Combined *operation performed.* If one eye has been lost, always a preliminary iridectomy. I seldom irrigate; if I do I use normal saline solution. Had little experience with dionin, but in three cases it certainly seemed to assist. Results as good as in mature cases, with equally good vision. A large percentage of my cases required discission of capsule, but so do mature cases. Postopera[illegible]flammation not frequent if lens matter is removed by gentle [illegible]ore difficulties attending extraction [illegible] cortex is removed by stroking cor[illegible]e cases removed by irrigation. Have [illegible]ve been doing it for ten years.

[illegible]: Yes, in patients 55 and over who have lost vision in both eyes for pleasure and business. The order of preference in the form of operation to be performed is: First, preliminary iridectomy, with extraction later; second, extraction with the combined operation; and third, simple extraction. Various circumstances and conditions guide me in the selection of the operation. Irrigation when employed is with normal salt solution. Dionin is not used. Generally speaking, the results in extracting immature senile cataracts have been equally as good in every respect as the results in extraction of mature senile cataracts. Secondary cataracts requiring operation are present in perhaps 90 to 95 per cent. of the cases. There is also a greater tendency to iritis unless preliminary iridectomy has been done. The difficulties in extracting an immature cataract are those concerned in the removal of all of the lens. I have no objection to the extraction of immature senile cataracts *if loss of vision* warrants the operation.

Würdemann & Black, Milwaukee: Yes, in patients over 45 whose vision in both eyes is below 6/60. Preliminary iridectomy and secondary extraction is preferred, and the anterior chamber is irrigated with normal salt solution. Dionin to promote absorption of débris is used in powder form. Results as satisfactory as in the extraction of mature cataracts. About 50 per cent. of our cases require secondary operations, and about the same number exhibit inflammatory reaction. Extraction of immature lenses usually requires larger corneal incision, and it is more difficult to complete the toilet properly. There is also a seeming greater predisposition to glaucoma following these operations. We have no objection to the extraction of immature cataracts when the vision is reduced as stated.

J. E. Colburn, Chicago: Yes, in patients over 60 with vision reduced below the patient's needs in both eyes. Have operated successfully at 48, 51 and 54. The form of operation to be performed depends on conditions presented. Sometimes preliminary iridectomy, sometimes the combined operation, and occasionally simple extraction. Irrigation of the anterior chamber is not employed, but dionin has been used in some of the later cases. The results in the extraction of immature cataracts have been as good as in the mature cataracts, other conditions being the same. Secondary cataracts are frequent, though inflammatory reaction from the operation is no more frequent than in the mature cases. No particular difficulties have been encountered, but it is important that the opening in the capsule be carefully and freely made. I have no objections to the operation other than those that would hold in any other form of extraction at any time.

J. T. Carpenter, Philadelphia: Yes, in persons past 50 years of age, whose vision in both eyes has been reduced so as to interfere with vocation. Preliminary iridectomy is always performed, usually with trituration of the lens. Irrigation never used except such as occurs with the use of the ordinary dropper and normal saline solution. Believe that dionin is useful in promoting absorption of the débris. Results are rather less favorable in extraction of immature cataracts than in the mat[illegible] secondary cataracts are almost invariably [illegible] is much more frequent than in the mature [illegible] encountered in the operation are the failure to get rid of the transparent sticky cortex. Objections to the operation are that there are greater difficulties connected with the operation, and a greater risk of inflammatory sequelæ. These, however, should not deter one from operating when vision has become so poor as to prevent the patient from getting around easily.

J. L. Thompson, Indianapolis: I do not like to operate on immature cataract if I can possibly put the patient off, but have been compelled to do so in a number of cases on account of the impatience of many of my patients who have become tired of waiting from year to year. In the cases of nuclear cataract in elderly persons, I extract without an iridectomy if the pupil dilates nicely, but in those which do not, I make a small iridectomy. I find that I can press out more of the cortical substance when an iridectomy is made than I can in simple extraction. The pupils look clear immediately after the operation, and moderately so at the first dressing, but soon begin to look hazy, and in most instances months elapse before the pupil clears up. I never now resort to any ripening process except in complicated and doubtful ones, when I make a preliminary iridectomy at least two months beforehand. In these cases the lens generally ripens of itself in a very few weeks without any further interference. Occasionally in these cases I have seen an acuity of vision of 20/20, but that is rare, even though a beautiful clear central pupil was obtained. My experience teaches me that a preliminary iridectomy is the safest *of all procedures for ripening the lens, even though the capsule* has not been touched. I used to irrigate the anterior chamber, but have abandoned the practice, as I did not find much benefit therefrom. I have had no experience with dionin. I have not found inflammatory reaction after the extraction of immature cataracts more than in cases of ripe cataract. The only objection I have found to operations of this kind is the great length of time it takes for the eye to clear up. I have had cases last nine months, supposi[illegible] on the capsule would have to be made, [illegible] see to go about with the other eye I put [illegible] time to time, dreading as I do secondary [illegible]ion, when to my surprise the patient would later come in smiling and with the exclamation "I can see," and on examination I have found a perfectly clear pupil.

A. R. Baker, Cleveland: Yes, in those of any age when useful vision in both eyes has been lost, and the operation is not otherwise contraindicated. Preliminary iridectomy is always preferred. Neither irrigation nor dionin have been used. Results have been almost as good as in mature cases, but secondary operations are more frequent. Inflammatory reaction is no greater than in the mature cases. No special difficulties have been encountered, and I have no objection to the operation.

Robert Sattler, Cincinnati: I make it a rule from which I rarely deviate not to extract immature cataract so long as the fellow eye has a fair degree of vision. I do not hesitate, however, if the fellow eye is defective, and there is an advance of the amblyopia, to do the operation with a preliminary iridectomy. Irrigation is not used, and I have had no experience with dionin. As compared to extraction of mature cataracts, the results are equally favorable, though ultimate good vision requires discission of secondary cataracts. I have no objection to the operation if the other eye is lost and functional examination and health of patient offers no contraindications.

Eugene Smith, Detroit: Yes, in persons 65 and upward whose vision in the eye to be operated has been reduced to counting of fingers, and vision in the fellow eye is useless or rapidly becoming so. The combined operation is preferred, though in suitable cases the simple operation is performed. Irrigation is not practiced, and experience in the use of dionin is too limited to pass an opinion as to its efficacy. Results as compared to mature cases are about the same, though [illegible] requiring operation are more frequent, as also [illegible] from the operation. Some cortex usually re[illegible] absorbed in the course of time. I have no objection to extraction of immature lenses in suitable cases.

Oscar Dodd, Chicago: Yes, in persons of any age when the vision in both eyes gets so low that business is interfered with. Preliminary iridectomy is preferred, but in many the combined operation is performed. Occasionally in selected cases simple extraction is done. Irrigation of the anterior chamber is not practiced, and while dionin has been used, its effects in my practice have been questionable. Results as compared to mature cataracts are equally good, though secondary cataract requiring operation is more frequent, and inflammatory reaction is also usually greater. Operation in these cases is more difficult, because it is hard to remove all of the soft cortex. I have no particular objections to the operation, but expect a longer time in obtaining satisfactory results.

Charles W. Kollock, Charleston, S. C.: Yes, in patients of any age in whom vision in both eyes has been sufficiently impaired so as to prevent going about, attention to business, or to seriously affect the nervous system. Preliminary iridectomy and extraction later is preferred, but the form of operation selected is the one that in each individual case seems best for obtaining good results. Irrigation of the anterior chamber is not practiced. Have had no experience with dionin. Results [illegible] mature cataracts are satisfactory. [illegible] operation are not more frequent in [illegible] ima-[illegible]y a little [illegible] ob-[illegible].

[illegible] Akron, Ohio: Yes, in patients of any age, [illegible] over 55 when there is need of the operation to restore useful vision. In those over 55 the vision in each eye should be reduced below 6/60. The combined operation is preferred, although occasionally a preliminary iridectomy is done. Irrigation of the anterior chamber is seldom practiced, but if so sterile water or physiologic salt solutions are employed. Have had no experience in the use of dionin. Results have been just as good as in extraction of mature cataracts, though secondary cataracts requiring operation are more frequent, and inflammatory reaction from the operation somewhat greater. The difficulties encountered are those concerned in the removal of the lens in its entirety. My objection to the operation is that secondary cataracts are more frequent, with attending risks of the secondary operations. I advocate the operation in those in whom the vision of both eyes is poor. If the vision of the other eye is good I do not operate unless the cataract has remained in the same state of maturity for a long time, and there is special reason for doing the operation.

C. D. Wescott, Chicago: Yes, in persons over 60, and have even operated on persons but little over 50 when vision in the eye to be operated on is no longer useful and vision in the fellow eye is failing rapidly. Preliminary iridectomy and extraction later is practiced in all cases of immature cataract. Irrigation is not employed, and two experiences with dionin have given doubtful results. As compared to extraction of mature cataract, results have been equally good, though discission has to be performed a little more frequently, and inflammatory reaction is also a little more frequent. I have no objection to the operation if the patient's necessities make it desirable.

F. T. Rogers, Providence, R. I.: Yes, in patients of any age if the general health is good, and when the vision in both eyes is so poor that the person can not go about easily or safely. Preliminary iridectomy is preferred and irrigation with normal saline solution is employed when indicated. Have had no experience with dionin. Results are quite as good as in the extraction of mature cataracts, though secondary operations are more frequent, as also inflammatory reaction. The difficulties encountered are those concerned in the removal of the soft lens material. Do not object to extraction of immature senile cataracts under conditions named.

George F. Suker, Chicago: Yes, in persons beyond 50 who count fingers faintly at 4 feet with the eye to be operated, and have about the same vision or a trifle better in the fellow eye. Preliminary iridectomy is preferred, though other forms of operation are sometimes selected, depending on circumstances. Irrigation of the anterior chamber with normal saline solution is employed, as also the use of dionin to promote absorption of débris. Results are as good as in extraction of mature cataract, though there is a greater tendency to the development of secondary cataract, and a tendency to greater inflammatory reaction, though this is not to be feared. The soft cortex is somewhat more difficult to remove. From a purely surgical standpoint I have no objection to the operation: it all depends on whether the patient is willing to wait for maturity or not, or on the time it takes the cataract to mature, even though the patient be willing to wait. Social environment is also a determining factor.

E. A. Shumway, Philadelphia: I prefer to wait until the cataract is mature unless social conditions are such as to make speedy restoration of visi[illegible] such cases preliminary iridectomy is of g[illegible] much cortex remains, irrigation of the a[illegible]cic acid solution should be used, with the [illegible] case of deeply set eyes, that the wound does not remain submerged in the fluid, as it collects in the conjunctival cul-de-sac. I have seen one case at least in which I thought infection took place in this way. I believe that dionin has a very decided influence in the absorption of lens débris, just as in the absorption of exudates, and that its action depends largely on the local reaction which it produces.

W. A. Fisher, Chicago: Yes, in patients of any age when the vision in both eyes is too poor for ordinary pursuits. The simple operation is invariably performed. Irrigation is not employed, and experience in the use of dionin for the resorption of lens débris has been limited. Results are just as good as in extraction of mature cataract, though secondary operations are slightly more frequent, as also inflammatory reaction. No particular difficulties have been encountered, and I have no objection to the operation.

Wendell Reber, Philadelphia: Yes, in patients over 60 who have less than 5/25 vision in each eye. Preliminary iridectomy is invariably performed. Irrigation of the anterior chamber is not employed. The use of 10 per cent. solution of dionin is invariably a rule. As compared to mature cases, my results show a trifling advantage in favor of the mature cases. Secondary cataracts are probably a little more frequent, and low iritis is the rule in almost all cases after extraction of immature cataracts. The presence of large quantities of cortex after the removal of the nucleus forms *the element of difficulty in the operation. I have no objection to* the extraction of immature senile cataracts that would not apply to any other cataracts.

E. C. Ellett, Memphis, Tenn.: I am much in favor of operating on unripe cataracts in one-eyed people, and people with double cataract when the vision of the best eye is so reduced as to interfere with safe locomotion and keeping the patient from working generally. I always do the combined operation in all cases, and in immature cataracts, if there is no objection to operating twice, I *prefer to do a preliminary iridectomy.* I do not find vision much of a guide as to maturity, as some eyes with a small central opacity see very little, while others with considerable peripheral opacities see very well. I operate when the patient is seriously inconvenienced by the cataract, no matter what the age. I irrigate the anterior chamber with normal salt solution, and by the practice have usually succeeded in removing practically all the cortex, thus making it unnecessary to use dionin. I have never had any trouble arising from the extraction of immature cataracts, and unhesitatingly recommend the practice. My views on this subject have already been briefly stated in an editorial which appeared in the *Ophthalmic Record* about one year ago.

Peter A. Callan, New York City: Yes, in persons over 40 whose vision in the eye to be operated on has been reduced below 20/70, *and whose vision in the fellow eye is reduced to 20/40.* Preliminary iridectomy and extraction later is invariably preferred. Irrigation of the anterior chamber with normal salt solution is performed when indicated, and dionin to promote resorption of débris is employed two weeks after the operation. Results have been as good as in the extraction of mature cataracts, though it is longer *until the eye is free from irritation. Secondary cataracts are* more frequent. I have no hesitation in operating on any immature lens, providing the needs of the patient require interference.

Allen Greenwood, Boston: Yes, in persons of any age when the vision in both eyes has been so reduced that coarse print can not be easily read. The combined operation is preferred, though the simple is preferred in suitable cases. Irrigation with normal salt solution is practiced, but I have had no experience in the use *of dionin. Results have been equally as good as in extraction of* mature cataracts, though secondary operations were required in about 50 per cent. of the cases. There is usually somewhat more inflammatory reaction, probably due to irrigation, but this promptly subsides under proper treatment. I have no objection to the operation in suitable cases.

Melville Black, Denver: Yes, in those cases in which the progress of the lenticular opacity in each eye is such as to cause lowering of vision beyond the useful point. If the patient has no occupation and is much inconvenienced by not being able to read, I should consider operation warranted. If a man with an occupation is no longer able to follow it because of poor vision, then his condition would warrant operation. I do not believe we are justified in requiring old people to wait for cataracts to mature if the opacification is *advancing equally in each eye, because such* persons may have wasted the only remaining months or years in which they might have been able to enjoy the fruits of vision obtained by operation. I prefer the simple operation, and employ irrigation of the anterior chamber with physiologic salt solution. Dionin is used a few days after the extraction to promote resorption of the débris. Results have been as good as in the extraction of mature cataracts, with about the same number of secondary cataracts requiring discission. Have not had inflammatory reaction, as a rule.

C. J. Kipp, Newark, N. J.: Yes, but not from choice, in persons of any age who as a result of lowered vision are unable to pursue occupation. The combined operation is generally preferred, though preliminary iridectomy is occasionally performed. Irriga*tion is not practiced and dionin has not been used. Results have* been less satisfactory than in the extraction of mature cataracts, for secondary cataracts requiring operation are nearly always to be expected, and the imperfect results as to vision form a decided objection to the practice.

J. S. Kirkendall, Ithaca, N. Y.: Yes, in those persons whose vision has been so seriously reduced as to inconvenience them in ordinary pursuits. The combined operation is performed, with large corneal section. Irrigation is not employed, and I have had no experience in the use of dionin. In all my cases of immature senile cataract I have had good results. Have had no inflammatory reaction of any consequence, but have always been obliged to do a discission. I do not hesitate to remove an immature cataract, all things being equal, but I prefer a mature cataract *if patient will wait.*

H. B. Young, Burlington, Iowa: Yes, in persons whose vision has been reduced so that it is difficult to get about safely. The simple operation is preferred, but combined operation sometimes accepted, depending on the nature of the case. Irrigation with physiologic salt solution is employed, but have had no experience in the use of dionin. Ultimate results compare favorably with results secured in mature cataracts. Discissions are generally required, for I prefer peripheric capsulotomy. The inflammatory reaction is no more serious than in the extraction of immature senile cataracts if conditions are otherwise good.

L. D. Brose, Evansville, Ind.: Yes, in persons of any age when the vision in both eyes is insufficient for the patient's needs. Preliminary iridectomy is preferred, otherwise the combined opera*tion. Irrigation is not employed, and experience with dionin is* limited. Results have not been quite as satisfactory as in the extraction of mature cataracts. Secondary operations are more often required, and inflammatory reaction is more frequently encountered. The objections are that such operations not infrequently require a *secondary cataract operation*: are more liable to be followed by inflammatory reaction, and hence apt to have a more prolonged recovery period: and the shallow anterior chamber requires greater care in making corneal sections.

Charles S. Bull, New York City: Sometimes operate immature cataracts in patients over 40 years of age in whom the vision of the eye to be operated on has been reduced two-thirds or more, and vision in the fellow eye lost or practically so. Preliminary iridectomy and extraction later is preferred, and irrigation with normal salt solution is employed. Dionin is not used. Results are not quite as satisfactory as in mature cases, owing to less acute vision. Secondary cataracts develop in about 40 per cent. of the cases, though inflammatory reaction has seldom occurred. In these extractions the difficulties are in removing all of the soft lens matter, and the manipulations increase the danger of loss of vitreous. I never extract aan immature senile cataract except to help *the patient's physical or mental condition, as, for instance, when* the other eye is blind or useless.

Harrold Gifford, Omaha: I extract immature senile cataracts only when I have to do it, i. e., when the patient needs sight and the cataract fails to mature after discission of the capsule. Age is not regarded. If the vision of the best eye gets so poor as to make life a burden, I urge a preliminary iridectomy, and in from two to eight weeks make a discission of the capsule, followed by extraction in from two to ten days. I seldom irrigate, but believe it worth while in *some cases. I have not used dionin in this class of* cases, but believe the indication is clear and shall try it. Results as compared to the extraction of mature cataract are not quite so good, as the vision is less acute, development of secondary cataract requiring operation, as also inflammatory reaction after the operation, are more common. My objection to the operation is the difficulty of expelling the cortex, or at least telling when all of the cortex has been expelled: hence the uncertainty as to when attempt at expulsion should cease. The cortex remaining favors infection and secondary cataract.

Lucien Howe, Buffalo: I very seldom extract immature senile cataracts, as the risk is usually unnecessary, and the results from any standpoint are not very satisfactory. When I do operate on these cases I prefer preliminary iridectomy when possible to get consent *for it, with irrigation with 1 to 10,000 sublimate solution if indi*cated. Dionin is not used. The development of secondary cataract and inflammatory reaction from the swelling of the clear lens fibers are sequelæ which *form a contraindication to the operation.*

Myles Standish, Boston: I have had comparatively little experience in extracting immature senile cataracts, as I never operate *under such conditions unless the case imperatively demands it.*

George C. Harlan, Philadelphia: I do not operate on immature senile cataracts by choice, as in these cases there is an increased *liability to the development of secondary cataract. Inflammatory* reaction from the operation, and occlusion of the pupil. I am more inclined to do the operation in those of advanced age in whom the vision in both eyes has been reduced so that the individual is unable to read. In these cases preliminary iridectomy is *preferred. Have had but little experience with irrigation, but* consider physiologic salt solution the best for the purpose. Have had no experience with dionin. General results as compared to the extraction of mature cataracts are not as good.

Charles A. Oliver, Philadelphia: No, for the reason that the final results are nearly always sooner or later more or less bad. In a very limited number of cases, for peculiar sociologic reasons, I sometimes operate these cases at any age, when the vision in the eye to be operated on has been reduced to finger counting, and in the fellow eye has been practically lost. In these cases combined operation is usually performed, though occasionally preliminary iridectomy followed by extraction. Irrigation, with normal salt solution through a McKeown irrigator is employed, as also the use of dionin to promote resorption of lens débris. These extrac*tions are nearly always followed by the development of secondary* cataract requiring operation, as also inflammatory reaction from the operation. The permanent ultimate vision is always better after the extraction of mature cataract.

L. Webster Fox, Philadelphia: No, I do not extract immature [illegible] not believe in taking the risk of serious [illegible] ch nearly always take place and render [illegible] rable.

[illegible] ids, Mich.: No, as there is a greater lia- [illegible] ions necessitating operative work and [illegible] or.

[illegible] I do not extract immature cataracts if [illegible] the lenses are both about equal I triturate and then extract. In cases where I have extracted lenses slightly immature I have had trouble with the cortex. I avoid this either by waiting or by triturating one of the affected eyes.

George H. Keiper, Lafayette, Ind.: Have had no experience in the extraction of immature cataracts.

DISCUSSION.

Prof. J. Hirschberg, Berlin, said that uveitis, a complication of cataract not mentioned by Dr. Bulson, is very difficult to diagnose, not only in the affected eye, but in the other as well. The views regarding operation on unripe cataract, Professor Hirschberg stated, are poetical but wrong. Physicians are told that the mature cataract is like a pea in a pod, and that when opened it pops out entire, but Professor Hirschberg's experience is that some of the cortex will remain. In unripe cataract he always advises a large opening. If the patient is more than 50 years of age cataract comes out easily. In lamellar cataract in individuals of 30 or 40 he operates without any preparation.

Dr. S. D. Risley, Philadelphia, asked Professor Hirschberg if he would consider it justifiable to operate on a ripe cataract, traumatic or otherwise, with the other eye good, if the patient had to work among machinery, for example, where his life might be endangered because of the blind side, to which Professor Hirschberg replied in the affirmative.

Dr. J. A. Bach, Milwaukee, stated that in his experience in unripe cataracts the removal of the anterior capsule is much to be preferred to the simple tearing or large section. With a good capsular forceps it is a simple matter to remove most of the anterior capsule, and by so doing we are assured of a cleaner result than can be obtained by simple section. The curling up of the anterior capsule is not always so ideal as one could wish, and then again, lens substance often adheres with great tenacity to these curled up portions of the capsule. A gentle washing out of the anterior chamber after removal of the lens is often of great advantage and dislodges particles that otherwise would remain.

Dr. William Campbell Posey, Philadelphia, declared that ever since he has had patients to operate on he has followed Dr. Hirschberg's teachings and removed cataracts as soon as the vision in the good eye fell so low that the patient could not perform the ordinary duties of life, for he could not convince himself from what he had seen in his practice and in that of others, that it was desirable to wait until the lens had become thoroughly ripe before attempting its removal. His results have been equally as good in the removal of immature cataracts as in the removal of mature ones; indeed, he believes that if by waiting until the lens is thoroughly ripe, the cortical substance is more apt to adhere to the capsule and to occasion secondary cataracts and iritis than when the operation is performed in the immature stage. The corneal section must be large and iridectomy should be performed.

Dr. Eugene Smith, Detroit, said in regard to operating on immature cataracts that he believes that there is altogether too much fear on the part of the operators derived from textbook teaching. When the exigencies of the case require it, there is no more objection to operating on a cataract three-fourths ripe than on one fully ripe, and not as much on those overripe. He has been in the habit for years of doing it. The question of removal of the capsule, he said, is interesting, because he always removes the anterior capsule, and for fifteen years he has advocated that procedure. There is less danger from cortical matter and better chance for absorption when the anterior capsule is removed.

Dr. C. R. Holmes, Cincinnati, substantiated what has been said with regard to removal of unripe cataracts. It has been his practice for twelve to thirteen years to remove cataracts when the exigencies of the case demanded it, even if they were only one-half ripe. He has yet to find a single case where he regrets having operated on a partially ripe cataract.

Dr. Albert E. Bulson, Jr., declared his regret that he did not have time to complete the reading of his paper, so that the part dealing with the technic of the operation, including irrigation of the anterior chamber, use of dionin, etc., could enter into the discussion by members of the Section. There is a difference of opinion as to the advisability of operating for immature senile cataract, and the manner in which the operation shall be performed when indicated. Generally speaking, the majority of the ophthalmologists whose opinions were solicited, do not hesitate to operate in these cases, and they report satisfactory results. A few prominent ophthalmologists refuse to operate for immature cataract of any description. Dr. Bulson agreed with Professor Hirschberg that it is difficult to recognize mild uveal disturbance when the lens is clouded sufficiently to make an ophthalmoscopic examination unsatisfactory, and for that reason some poor results are due to the existence of mild pre-existing intraocular disturbances rather than to any ill effects directly associated with the operative procedures. Dr. Bulson confessed that he has learned to expect a certain amount of iritis following the extraction of immature cataract. The inflammatory reaction is undoubtedly due to trauma, more especially that accompanying irrigation of the anterior chamber, but with early and continued use of atropin and dionin he has not had any difficulty in controlling the inflammation. He considers dionin a valuable remedy in the postoperative treatment of cataracts. While the effect of the drug is questionable in some cases, in the majority it has a remarkable effect in promoting resorption of the cortical remains, thus reducing the possibility of necessity of secondary operations.

Educate.—All government by the people is made better when the people come to know and feel its deficiencies. No abuse can survive long when the people have located it. When the masses know what hurts them, that particular wrong must cease.—David Starr Jordan.

A PRELIMINARY REPORT ON CELLS FOUND IN YELLOW FEVER BLOOD, WITH REFERENCE TO THEIR ETIOLOGIC AND DIAGNOSTIC SIGNIFICANCE.

DRS. O. L. POTHIER, JOSEPH HUME, F. H. WATSON
AND M. COURET.
NEW ORLEANS.

A careful study of yellow fever blood has shown the regular occurrence of certain cells hitherto either unnoticed or not described, which seem to be undergoing developmental changes and which can be demonstrated in the stomach of a recently infected stegomyia. These cells are entirely extracellular, though occasionally some are seen lying on the red cells; on one occasion one was distinctly seen lying within the protoplasm of a polymorpho-neutrophilic leucocyte. They occur, as a rule, alone, though two or more may sometimes be noticed lying indefinitely grouped. They vary in size from twice the diameter of a pneumococcus to one-fourth the diameter of a red cell, and vary in shape from an ovoid to a sphere, and oft times come to a focus in a higher plane than the surrounding red cells. When stained they show, as a class, a highly granular neutrophilic protoplasm surrounding a nucleus which contains one or more deeply staining chromatine granules; the protoplasm is limited by a capsule which is of considerable thickness in the older forms.

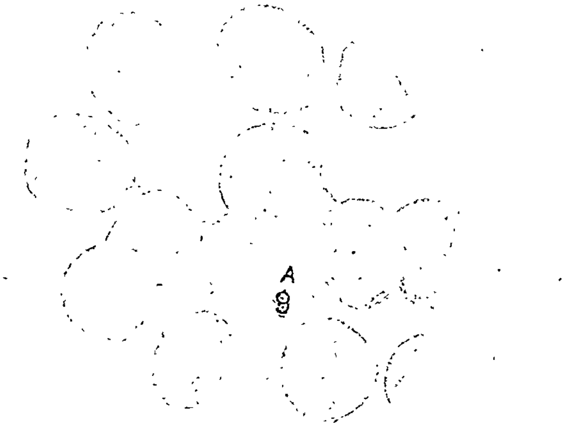

Fig. 1.—Type A, young form, surrounded by a pseudocapsule (1,300 diameters).

The following forms, with minor variations, have been observed:

A. Small, deeply staining neutrophilic bodies about twice the diameter of a pneumococcus and often lying in pairs; sometimes fine chromatin granules can be made out within these; again none can be seen. This form is found chiefly and in greater abundance within the first twelve hours of the disease, and is difficult to detect, as they can be easily confused with various artifacts (Fig. 1).

B. An ovoid or pear-shaped form, with a diameter about one-sixth to one-fourth the diameter of a red cell and a width of about one-third its own length. This has a well-marked nucleus, containing chromatin granules and a narrow rim of neutrophilic protoplasm. This form has been seen in what is taken to be a budding process; again it has been seen in dumb-bell form (Figs. 2 and 3).

C. This has been found in blood taken at any time in the first three days. This form is circular or sphere-shaped and approaches in size that of a microcyte; it has a neutrophilic protoplasm, a definite nucleus always containing several chromatin granules; the whole surrounded by a well-defined capsule (Figs. 4 and 5). It may be mistaken for blood platelets, which it resembles in size, especially when the platelets show much differentiation in staining. But the periphery of the platelets is always slightly wrinkled and irregular—never the case with the cell under description, and in the platelets any granulation which may exist is always found exactly on the periphery and never within the protoplasm.

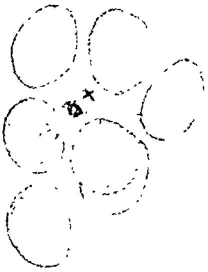

Fig. 2.—Type B. well marked nucleus, chromatin granules, narrow rim of plotoplasm (850 diameters).

D. A large cell which has a definite central nucleus surrounded by a finely granular protoplasm, which at its periphery is indefinitely limited and shows no marked capsule. This form is rare as compared with the previous ones, and is found chiefly on the second and third day (Fig. 6).

The blood has been taken from various parts of the body during the day and night, and from six hours after the onset to the eighth day of the disease. The described cells have only been found after the third day, that is on the fourth, and no relationship could be traced between their frequency and the severity of the disease. Fresh blood, by slide and hanging-drop methods, gave negative results, though on several occasions it was thought that the cells were seen; but there are so many objects in fresh blood which may be mistaken for them that at present this method is very uncertain. The examination of the spinal fluid likewise proved negative. In specimens taken from the same patient at the same time one slide may often be negative, while all the others are positive; this is probably due to the scarcity of the cells in the peripheral blood, for it is unusual to find more than four or five cells to a whole slide even after a three- or four-hour search, and it is exceptional to find as many as twelve in a single slide. It is easy to overlook them and much time has to be given to each specimen before it can be called positive or negative.

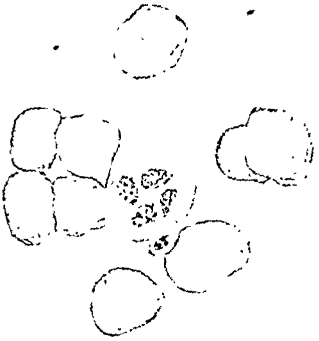

Fig. 3.—Type B, slightly older form than Fig. 2 (900 diameters).

Fifty-two slides of yellow fever blood taken in the first three days were examined, representing thirty-five separate cases. The described bodies were found in all of these save three. Two of these negative slides were duplicates of positive ones, and in the third malarial organisms were found, and clinically the case was indefinite. Many other slides taken on the fourth to the eighth day of the disease, inclusive, were examined with negative results, except once, when the cells were found on the fourth day.

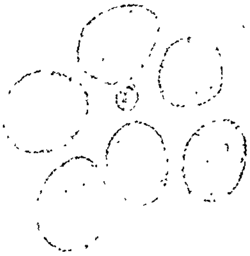

Fig. 4.—Type C, deep staining nucleus, narrow rim of protoplasm surrounded by a definite capsule (850 diameters).

These cells are very poorly and indifferently stained by the usual methods. With Wright's, Erhlich's triacid, eosin and methylene blue, etc., they are but feebly stained and their detection difficult. After trying many stains, the following was found to give almost perfect results: The blood was fixed by immersing the slide in methylic alcohol for two minutes, after which it is air dried. It is next stained with Delafield's hematoxylin for three minutes, acid alcohol till reddish-brown, am-

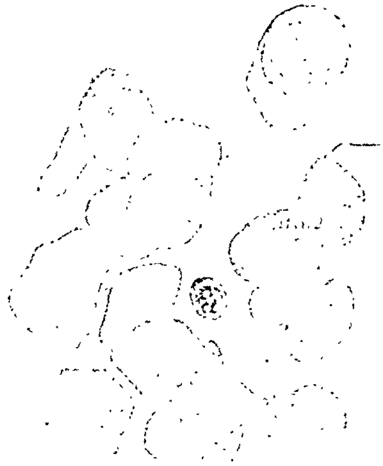

Fig. 5.—Type C (1,300 diameters).

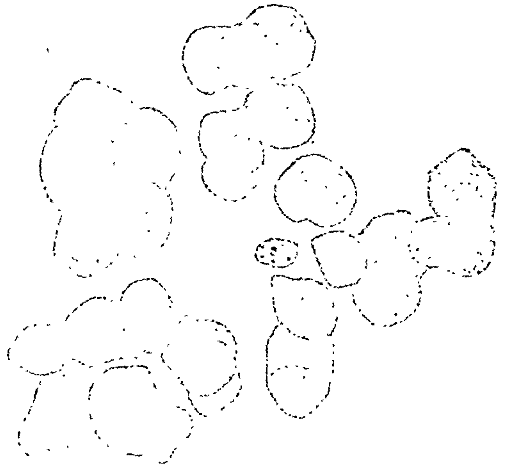

Fig. 6.—Type D (850 diameters).

monia water till blue, wash with water and stain for fifteen minutes with an aqueous solution of eosin. 1/1000, wash and dry and clear with oil of cloves and mount. [illegible] licker method gives almost as good results, viz., after fixing stain with 0.5 per cent. eosin in 50 per cent. alcohol for one minute, wash and stain with Delafield's hematoxylin for three minutes, clear, dry and mount.

With this method the nucleus stains deeply and shows two to four chromatin granules; the protoplasm stains a light bluish-pink and is surrounded by a definite membrane which is more deeply stained. In this well-defined limiting membrane a rather large, deeply stained spot, situated in one pole, can often be made out, often accompanied by several smaller ones.

Every effort has been made in this work to avoid sources of error. The stains have been filtered, sterilized and examined with negative results for similar bodies. The slides and the skin of the patients have been likewise carefully cleaned, and as control 100 specimens of blood have been examined, taken at random from patients in the Charity Hospital. Thirty-five of these were stained by the same technic as that employed for yellow fever blood and most carefully examined with absolutely negative results. The others were stained by all the methods in vogue and with negative results. Four slides from yellow fever cases which were taken in Vera Cruz, Mexico, during the epidemic of 1902, showed the same bodies. Again, seven numbered slides which were submitted to us for examination were correctly diagnosed; four were from yellow fever cases on the second or third day, two from each case and three from other diseases. One yellow fever slide was alone miscalled as negative, but its duplicate was correctly stated to be positive. In several instances plasmodia malaria were found in the blood of patients ill with yellow fever, controverting the opinion that the two infections can not occur together.

Stegomyia raised from the egg and fed on normal humans or bananas and some which were not fed at all, but allowed to bite patients a few days after birth, showed in smears made from blood obtained from the stomach, the same bodies which we have previously described as occurring in the blood of yellow fever patients. In mosquitoes examined later than nine hours after feeding we could not demonstrate these bodies owing to the partial digestion of the blood. Mosquitoes raised at the same time, fed only on normal individuals and examined at the same interval of time showed no such bodies. Results of studies on mosquitoes at later periods of infection will be reported later.

We wish to thank the officers of the Isolation Hospital for the facilities they have given us; also the house surgeon and internes of the Charity Hospital for their interest and aid in following the cases.

Medical Group in Parliament.—The numerous physicians who are members of the French senate or house of deputies, for ten years have been in the habit of meeting apart to discuss measures affecting the public health, etc., before legislating on them. Italy has also a large proportion of medical men in its parliament, and they have recently organized in the same way. In order to become better posted on certain subjects they have issued an appeal for the holding of a special congress of physicians in the state employ, sanitary officials, pharmacists and veterinarians, to confer with the physicians in the legislature in regard to legislative matters. The physicians in the senate style their group the "*fascio medico parliamentare.*"

Special Article

IMMUNITY.

CHAPTER XXVI.

PLAGUE.

Plague was known in the second and third centuries. In the sixth century it ravaged the Roman empire and destroyed half the population in the eastern provinces. Under the name of the "black death" it swept over Europe in 1347-50 with a sacrifice of one-fourth of the inhabitants—about 25,000,000. During the fifteenth and sixteenth centuries many epidemics prevailed in various parts of Europe, and the disease seemed to have fastened itself on that part of the world. It seems, however, that the pneumonic form, the most contagious, gradually became less common, or the virulence of the infection diminished, and this, with the institution of quarantine regulations, decreased the prevalence of the disease during and following the seventeenth century. Nevertheless, there have been occasional outbreaks in Eastern Europe since that time. Since the recrudescence of plague in Hongkong in 1893 and in other places later, the disease has been subjected to modern methods of scientific study, its cause has been discovered, and the importance of rigid quarantine measures at seaports in preventing universal extension of the disease has had practical tests.

Characteristics of the Organism.

In the Hongkong epidemic of 1893-4 Kitasato and Yersin, working independently, discovered the bacillus of plague, *Bacillus pestis.* The organism measures from 1.5 to 1.75 microns in length, 0.5 to 0.7 in breadth, is of long oval shape, typically, but presents many variations in form both in the body and in cultures. It may appear as a short oval (coccus form), or as a longer rod; and distorted and swollen, vacuole-like cells (involution or degeneration forms) are commonly met. The longer the disease has lasted, or, on the other hand, the older the culture, the more numerous are the atypical forms. In bouillon long chains develop. A knowledge of this pleomorphism is important from the standpoint of diagnosis. It is placed with a number of other organisms which cause hemorrhagic septicemias in animals, the members of which comprise the "group of hemorrhagic septicemia."

Polar Staining.

Like some of them, the two ends of the bacillus stain more densely than the central portion with methylene blue, dilute carbol fuchsin and other dyes (polar staining). It does not stain by Gram's method. A capsule may be demonstrated by appropriate technic. The organism has no independent motility and probably possesses no flagellæ. Spores are not formed. It may be cultivated from the blood, organs, bubos, sputum, stools and urine of patients (or animals), on agar, gelatin, bouillon or blood serum which are of neutral or slightly alkaline reaction. On agar in certain respects it resembles the influenza bacillus, and confusion with this organism is possible in cultures made from the sputum. Its appearance on gelatin and bouillon are more or less characteristic. In the latter medium the so-called "stalactite" growth occurs, in which visible processes extend from the surface toward the bottom, where they meet other processes which extend toward the surface ("stalagmites"). These formations utilize as their starting points the sides of a flask or drops of butter or oil which are placed on the surface. Certain other organisms grow in a similar manner.

Involution Forms.

It is said to be a characteristic feature of the plague bacillus that many involution forms appear on agar which contains 3 per cent. of sodium chlorid. The optimum temperature for growth is from 25 to 30 C., which is somewhat lower than that for most pathogenic organisms. It grows rather slowly even under the best conditions. In mixed cultures it is overgrown by more rapidly growing saprophytic organisms (e. g., colon bacillus), although little antagonism exists between them. It may live for from four to seven days in the putrefying organs of man or animals. Its virulence may be retained in the cadaver of a rat for two months (Bandi and Stagnitta-Balistreri). During this time the organisms penetrate all the tissues of the body, even growing through the skin. It may live in the pus of a bubo for twenty days when unmixed with other organisms (Albrecht and Gohn); in the sputum from plague pneumonia for ten days; in various foods, as milk, potatoes, for one to three weeks; in water from five to twenty days, depending on the number of saprophytes which are present; in earth from two weeks to three months, depending on the quantity of organic matter and other organisms. In all these instances the higher the temperature, i. e., above 30 C., and the more numerous the saprophytic organisms, the shorter is the life of the plague bacillus. In winter, when contaminating saprophytes grow less rapidly, the plague bacillus lives longer.

Resistance.

The resistance of the organism to desiccation, sunlight and disinfecting agents is rather low, particularly when the surrounding temperature is above 30 C. In temperatures of from 29 to 31 C., when thoroughly dried, it rarely lives longer than from six to seven days, whereas at lower temperatures, 16 to 20 C., cultures may be obtained after from one to several weeks, depending on the material which contains the organisms. It lives longer in woolen and cotton threads (clothing) than when isolated as in dust; hence, dust infection is improbable (Dieudonné). In sputum (plague pneumonia) and purulent exudates in which the bacilli become incrusted to a degree, life may persist for from three to four weeks. Sunlight kills them in from two to six hours, depending on the temperature and the proximity of the organisms to the surface. Although cultures for the purpose of vaccination have been killed at a temperature of 65 C. for one hour, precautions to insure an even distribution of the heat are necessary to render certain the death of all organisms. 100 C. kills them at once, and 80 C. in from five to ten minutes (moist heat). It is very resistant to cold, remaining alive at a temperature of —20 C. for several weeks, even when repeatedly thawed out during this time. It even proliferates slowly at from 4 to 7 degrees C.

Virulence and Toxins.

Cultures of the plague bacillus retain their virulence over a long period when kept in a cool dark place, and when not allowed to dry. However, they often lose in virulence unaccountably. The nature of the toxic substance is as yet obscure. A concentrated soluble toxin has never been obtained in cultures. Filtrates of young cultures show little or no toxicity, whereas in older cultures the fluid becomes more or less toxic (liberation of endotoxin?). Lustig and Galeotti extract cultures with 0.75 to 1 per cent. potassium hydroxid, from which they precipitate a toxic substance with acetic or hydrochloric acid. Markl found the cell bodies to be very toxic after eight weeks' growth at room temperature, provided the organisms were killed by chloroform rather than by heat; killing by heat destroys the toxic substance largely. He believes some metabolic product of the organs is the chief toxic constituent, claiming at the same time the presence of a certain amount of soluble toxin.

Virulence for Animals.

The plague bacillus is exceedingly virulent for rats, guinea-pigs and monkeys; somewhat less virulent for mice; other animals, cats, dogs, swine, cows, horses, sheep, goats, may be infected artificially, although they commonly recover even after large doses. Rats and guinea-pigs may be infected by subcutaneous, intraperitoneal and intravascular injections, by the feeding of infected material or by placing it on the nasal mucous membrane or in the conjunctival sac, and by inhalation experiments, the last method commonly resulting in plague pneumonia. Guinea-pigs die of plague septicemia in from four to five days when cultures or material containing the organisms (sputum, feces, organs from plague cases), are rubbed into the shaven or even unshaven skin (Albrecht and Gohn). This experiment is of value for the detection of virulent plague bacilli and is a convenient means of separating them from contaminating organisms. Following inoculation into a cutaneous or mucous surface a local reaction of varying intensity develops in which the subcutaneous tissue becomes edematous or even hemorrhagic, in a number of hours the regional lymph glands become swollen and hemorrhagic, and in from two to five days the animals die in a condition of plague septicemia. Cultures of low virulence not infrequently cause a chronic infection which is characterized by the formation of large granulomatous nodules on the surface of the liver and spleen, and in the omentum. Such foci contain many plague bacilli, and the death of the animal results in a few weeks from intoxication or from general infection. Although rabbits are much less susceptible than rats or guinea-pigs, young animals succumb to cutaneous inoculation.

Endemic Plague.

Dieudonné cites four foci in which plague is known to be endemic at the present time: One is in China (province of Yünnan), from which the Hongkong epidemic originated; a second in the Himalayas, which led to the outbreak in Bombay; a third in a mountainous region south of Mecca, and a fourth was found by Koch and Zupitza in British East Africa near the source of the White Nile.

Plague in Rats.

The opinion is held by many that plague is primarily a disease of the rat and that certain regions remain pest-infected over a long period because of this fact. It is known that rats often suffer from a chronic form of the disease, and it is possible that the organism at times acquires increased virulence, as a consequence of which the infection becomes widespread and rapidly fatal among these animals. It is probable that the chief method of transmission from rat to rat is through the eating of plague cadavers by healthy animals. The possibility of transmission from one animal to another by means of fleas is upheld by some. It has been shown that the blood which they ingest from an infected animal may contain bacilli, but transmission to other animals by this means is still disputed.

Plague Houses.

The means by which the disease extends from rat to man are not definitely determined. This much is known, however: First, that the bacilli are excreted in the urine and feces of infected animals; and, second, that the disease attacks those especially who live in dark, damp, filthy quarters in which rats are numerous. A great mortality among the rats not uncommonly precedes an outbreak of plague in man. Europeans who live under hygienic conditions in plague infected districts do not often contract the disease. It is suspected that the existence of "plague houses" may depend on the prevalence of the disease among the rats, which infest the houses. On the other hand, the organisms excreted by a plague patient through the sputum, urine or feces, find in the conditions described above, surroundings which favor their prolonged life; hence, the occurrence of subsequent infection in the same house in many instances may be traceable to a previous case.

Fleas.

The theory has been advanced also that fleas may be an important means of transferring plague from rats to man. This is objected to on the ground that every animal has its own peculiar flea and that the flea of the rat will not bite man. Nevertheless, it may alight on the skin of man temporarily and there discharge bacillus-laden excretions. Flies in a like manner may distribute the bacilli from rats or the infected excretions of man.

Epidemics.

Epidemics of plague lack the explosive-like suddenness in their development which characterizes cholera and to a certain extent typhoid and dysentery. The cases occur in groups and in particular houses in such a manner that direct and indirect contact seems to be largely responsible for its extension. Every epidemic of plague may be divided into three stages: a slow progression from small centers, an acme of widespread death, and a slow recession (Dieudonné). It seems probable that the disease spreads rapidly and extensively only when the pneumonic form prevails. In this instance infection by direct contact may occur through the inhalation of dried sputum or of infected drops of sputum or saliva directly from the patient. Even in ordinary speaking minute drops of saliva are thrown into the air. In the pneumonic and septicemic forms, the infected urine and feces contribute to the dissemination of the organisms. Transmission by indirect contact, as by infected clothing and linen, has been noted in many instances. Compared with pneumonic and septicemic plague the bubonic form is much less dangerous to a community.

When plague invades a new country it commonly makes its first appearance in coast cities. Presumably this is accomplished through infected rats which may board a ship during its stay in a pest-ridden harbor, and which subsequently escape at the new port.

Infection Atria.

In man infection takes place through the skin most frequently, although the mucous membrane of the mouth, nose, pharynx, tonsils or the conjunctiva are possible infection atria. Often no local reaction is produced, and the point of entrance may be indicated only in a general way by the swollen lymph glands of the region. Infrequently a pustule or small carbuncle marks the point of entrance. Primary plague pneumonia is caused by the inhalation of pest-laden material, particularly fine particles of sputum from a pneumonic case, and perhaps also by the inhalation of infected dust; the latter is probably of less importance because of the short life of the organism in dust. Infection is thought not to occur through the stomach or intestines.

The incubation period is commonly from three to five, and not longer than ten days.

Following cutaneous infection the regional lymph glands become swollen and hemorrhagic, and undergo more or less extensive necrosis. When the infection extends beyond the lymph gland the blood may contain enormous quantities of bacilli (plague septicemia), and the same condition follows plague pneumonia; in the event of general infection death follows in a few hours. "Secondary pneumonia" and also "secondary buboes" develop as a consequence of blood infection. Hemorrhages into the mucous membrane (especially the stomach or cecum), endothelial surfaces (pericardium), and various parenchymatous organs, with extreme degeneration of the latter (liver, kidneys and heart), are characteristic anatomic changes. The spleen is usually swollen. The toxic substance evidently has affinities for many tissues.

Mixed infection with the streptococcus is not uncommon and is a serious complication.

Prophylaxis.

The principles of prophylaxis rest: 1, In an early bacteriologic diagnosis by microscopic and cultural examination of blood, sputum and fluid taken from a bubo either by a syringe or after incision; 2, in the thorough isolation of patients and of those who have been exposed to infection; 3, in the disinfection of excretions, of clothing and of infected houses, which in some instances may mean the destruction of the latter; 4, in the destruction of rats; 5, prophylactic injections. Up to the present time the most effective measure of getting rid of rats is to offer a bounty for each animal caught.

Vaccines.

The vaccine of Haffkine has been used extensively in India. The Indian plague commission found that the incidence of disease and mortality were lower among the inoculated than the uninoculated, although many of the inoculated contracted the disease in a comparatively benign form. The vaccine consists of bouillon cultures which have grown for six weeks with stalactite formation (see above), then killed by exposure to a temperature of 65 C. for one hour; from 0.5 to 3.5 c.c. are injected, according to the age and size of the individual. One or more subsequent injections may be given. The local and general reactions are of moderate severity. Protection becomes manifest only several days after the inoculation and may persist for many weeks or months. The vaccine recommended by the German commission consists of two days' old agar cultures which have been killed by heat (65 C. for one hour). Lustig and Galeotti utilize the toxic precipitate described above as a vaccine. Terni and Bandi inoculate rabbits or guinea-pigs intraperitoneally with the plague bacillus and after or just preceding death collect the peritoneal exudate, in which the organisms are allowed to proliferate still further for twelve hours. The bacilli are then killed at a low temperature, and this fluid, after an addition of a preservative, constitutes their vaccine. Although the last three vaccines have proved of value in animal experiments, they have not as yet been used extensively in man.

Besredka, also Shiga, recommend the use of mixed active and passive immunization, already referred to under typhoid and cholera, in this instance naturally using plague bacilli (killed) and anti-plague serum. Shiga reported good results by the use of the combined method in the epidemic in Kobe.

Immunity.

The immunity which is produced by protective inoculation, like that which follows natural infection, is considered to be antibacterial inasmuch as the serum acquires increased bactericidal power for the bacillus, but shows no ability to neutralize its toxic constituents. As in relation to many other infections, however, we are not in position to ignore the possibility of an increased phagocytic power on the part of the leucocytes. The immunity which follows infection is of long duration.

Serumtherapy and Prophylaxis.

Prophylactic injections of antiplague serum produce a temporary immunity of about two weeks' duration. The Pasteur Institute prepares the serum of Yersin by immunizing horses first with killed and then with living cultures. The immunization is difficult and from several months to a year and a half are required for the production of a strong serum. When the blood is drawn eventually its freedom from living plague bacilli and from toxic substances must be assured. The immunizing value of the serum is determined by that quantity which will save a mouse from a fatal dose of living plague bacilli, the serum being given twenty-four hours in advance of the culture. This is accomplished by 0.1 to 0.02 c.c., depending on the strength of the serum. Its curative power is estimated from that quantity, 0.5 to 0.1 c.c., which saves a mouse when administered sixteen hours after the injection of an otherwise fatal dose of culture. For protective inoculation in man from 10 to 20 c.c. are recommended, and for curative purposes from 30 to 50 c.c. Concerning the value of this serum Dieudonné concludes as follows: "On the basis of the results obtained in man and in animal experiments we can attribute no positive curative value to the Parisian serum, although a certain influence on the course of the disease can not be denied. On the other hand, the serum is suitable for protective inoculation when immediate immunity is necessary, as for those who are caring for cases of plague pneumonia. Since, however, the protection afforded by this means persists only for a few days, subsequent active immunization with killed cultures is indicated as soon as possible for those persons who are exposed to infection for some time." The favorable results noted by a number of observers would seem to justify further use of the serum for curative purposes.

The serum of Tavel, prepared at the Institute of Bern, is, like that of Yersin, bactericidal and agglutinating. Antitoxic as well as bactericidal properties are claimed for the serum of Lustig, which is prepared by immunization with the toxic precipitate mentioned above. It has been used extensively in the treatment of plague and in a number of small epidemics favorable though not thoroughly convincing results were reported. The serum of Markl, which is supposed to be antitoxic, has had no practical trial. It is prepared by immunization with old cultures which have been killed by chloroform.

Agglutination.

Although the serum of patients acquires a certain agglutinating power, it is rather low (1/3 or 1/5), and does not become manifest until during the second week of the disease. Before this time diagnosis by clinical or bacteriologic means can be made with certainty, hence for clinical diagnosis the reaction has little value. On the other hand, a strong artificial agglutinating serum obtained by the specific immunization of animals is of great value for the identification of the plague bacillus when cultures have been obtained from suspected cases. Artificial serums may agglutinate in dilutions of from 1/1000 to 1/6000.

The protective power of vaccination was strikingly shown in the case of a nursing mother who contracted confluent smallpox; she was taken to the hospital with her seven months' baby. The infant had been successfully vaccinated fourteen days previously; it was not weaned, but was nursed by the mother throughout her illness, and was handled daily by about fifty other patients in various stages of smallpox; it left the hospital in perfect health.—H. J. Neilson, in *Brit. Med. Jour.*

Clinical Notes

AN UNUSUAL GONORRHEAL COMPLICATION.

JAMES A. NYDEGGER, M.D.
United States Public Health and Marine-Hospital Service,

Patient.—A young Swede, aged 21, of fair habits, who could not recall having ever before been ill, was admitted to the Marine Hospital, New York, June 14, 1905, with the following history:

History.—Having arrived in port after a somewhat prolonged voyage, he, in company with a number of his shipmates, visited numerous sailors' brothels in lower New York. The result was that a few days later he developed gonorrhea. There was a discharge from the meatus, and a short time after the discharge appeared he noticed a soreness in the right groin, on account of which he applied for relief.

Examination.—This showed, in addition to the discharge, a slight enlargement and tenderness of one or two of the superficial inguinal glands on the right side. Temperature and pulse were normal.

Treatment.—Rest in bed, a restricted diet, alkalines administered internally, an ice bag applied over the tender glands and a 1 to 4,000 solution of permanganate of potassium for irrigation of the anterior urethra were prescribed.

Result.—His discharge ceased in about a week, and the pain and swelling of the lymphatic glands almost subsided. The patient was able to be about in the ward. The urethral irrigation was continued.

Subsequent History.—On June 25, following a feeling of chilliness, there was elevation of temperature, and on June 26 the temperature went up to 39.8 c.; pulse was 84. He complained of chilly sensations at intervals. Irrigations were discontinued, and cold sponges were ordered to reduce temperature. The temperature took a downward course for three days, but did not reach normal.

On June 29 a tumor mass the size of a small hen's egg was made out above Poupart's ligament almost at the ilium. The tumor was painful on pressure, and it continued to increase in size. The mass could be fairly well palpated on deep pressure. There was doubt as to its nature and more doubt as to its exact location, whether it was intraperitoneal or extraperitoneal.

Blood Examination: This showed a leucocytosis of 16,300, and a differential count (500 cells) gave 75.5 per cent. polymorphonuclear cells. The temperature curve indicated also a rather severe infection.

Operation.—Under ether, an incision was made about an inch above and parallel to Poupart's ligament. It was about four inches in length, and extended well out over the anterior superior spine of the ilium. The peritoneum was reached, and being adherent to the mass, was pushed upward and backward with some difficulty. Following back between the mass and the peritoneum carefully, the mass was found to consist of a number of lymphatic glands closely surrounding the external iliac vein and artery, and bound together by their surrounding inflammatory tissues. The glands contained many foci of suppuration.

Owing to the depth of the involved glands and to their close connection with the large blood vessels, they were not wholly removed, for fear of wounding the vessels. A blunt-pointed probe was pushed into the glands in many directions, and subsequently they were broken down by the fingers and partially removed. The wound was packed with plain sterile gauze and left open. The portion of the glands left behind at the time of the operation and adherent to the vessels, subsequently sloughed away gradually, and the wound healed by granulation. The patient was discharged in early August.

Remarks.—The case is reported because of the apparent great rarity of such complication occurring in the course of an attack of gonorrhea. There was reasonable doubt before the operation as to the nature of the mass; there was also more doubt as to its location. It was difficult to say whether it was inside the abdominal cavity or outside the peritoneum, owing to its close proximity to that membrane. In its growth the mass had pushed that part of the peritoneum extending over it, upward. The necessity for the operation was indicated by the septic pulse curve, the degree of leucocytosis and the high percentage of polymorphonuclear cells in the blood. With a suppuration due to a highly virulent organism in the lymph glands surrounding the iliac vessels, there is considerable danger of rupture of the glands through the peritoneum into the general abdominal cavity, with a resulting peritonitis.

Dr. C. H. Lavinder of the Public Health and Marine-Hospital Service, in whose ward the case developed, first called my attention to it in consultation. The case was seen together a number of times and the opinions were divergent. Of course, there was always borne in mind the probable cause for the occurrence of the tumor.

In a rather extensive search of the literature of gonorrhea and its complications, I have been unable to find a single reference to a complication of this nature occurring in this location. I assume, therefore, that it is of rare occurrence. A glandular involvement of lymphatics of any nature in the course of a gonorrhea in the male is of rather infrequent occurrence, and then the superficial inguinal glands are the ones involved. Doubtless in the course of a gonorrhea other pus-producing organisms than the gonococci gain access to the lymph glands supplied from the genitalia, although these latter are capable of exciting violent inflammation. No other organisms were looked for in this case.

A CLINICAL CHART FOR THE RECORDS OF PATIENTS IN SMALL HOSPITALS.*

GEORGE F. WILSON, M.D.,
PORTLAND, OREGON.

In very many of the smaller hospitals throughout our country, a great deal of good work is done, and there is no question but that a careful record of this would prove useful, instructive and of benefit to science if it could only be observed in an accessible form.

Aside from the strictly scientific aspect of the matter, reference to the progress of a patient during a sojourn in a hospital becomes frequently important in a legal way, as a means of substantiating or refuting claims for damages, and as a groundwork on which an expert witness may base an opinion. Witness for instance the case of an individual with marked asymmetry of the chest wall. who claimed that his existing disability was largely due to his having his ribs crushed in a railroad train wreck. His hospital record showed no variations in pulse, respiration or temperature during the nineteen days immediately following the accident, yet had the case not been settled out of court, there were witnesses ready to swear that the deformity was not present before, and therefore must have been caused by the accident. In many such ways can the value of a careful record be shown.

Owing, however, to the small clerical force and the manifold duties of the resident staff in our smaller hospitals, but little time can be found for copying histories, even though they are taken carefully. The work is not instructive, or interesting to a student of medicine, and as I know, from my own personal experience, will be neglected if there is any possible way to do so. Excuses will always be found, or made, to shirk the work, consequently, unless such records can first of all be made in the simplest possible shape and afterward be preserved in the original form, they will be lost forever. A hospital, like any business, must keep a system of books, making a certain amount of clerical work a necessity, and after the admission of a patient, as a part of the business of the institution, there must be a method of showing what changes of rates are brought about by a transfer from ward to room, or vice versa, and what expense has been incurred in the way of operation, etc.

With the view of avoiding any repetition and simplifying the work as far as possible, to each patient, on admission, is allotted both a card and this chart on which are blank spaces for his number, name, date of admission, address, age, civil condition and occupation, religion and nativity, also the number of his room or ward, with the additional information on the card as to page of ledger, address of nearest relative, name of his physician, name of order or fraternity of which he is a member, and name of individual or corporation responsible for him. The card is kept at the office for the business part of the transaction, becoming, if deemed proper, an index to his chart when filed away, and an index to his ledger account. The chart is given to the nurse in charge of the patient. On the obverse of the sheet, immediately beneath the so-called pedigree, is a space for the diagnosis and name of attending physician or surgeon. Beneath this is recorded, under separate headings, any operation performed, with its date, the name of operator and assistant, the kind of anesthetic, total time, amount for narcosis, and total amount, and name of anesthetist, the kind of sutures, both *deep and superficial*, date of their removal, use of drainage and results as to infection. Below this, under the headlines, "Family History," "Previous History," "Present History," and "Examination," are spaces for recording these facts. Sufficient space to the right of this is reserved, under separate headings, for the results of blood examination and urinalysis. Near the lower margin are the results as to cure, improvement or not, with date of discharge or death. On the reverse side, under the caption "Bedside Notes," the sheet is so ruled as to give a space for a morning and evening record of pulse, respiration and temperature, a daily record of bowel and bladder function, diet, *treatment*, and remarks on the progress of the case. A sufficient margin is preserved on both sides for binding in book form, or with perforations to form a portfolio. Under bedside notes, one sheet will accommodate a stay in hospital of about one month: should, however, the sojourn be prolonged, additional sheets of these notes, with both sides alike, are provided for a continuation of the history, all being bound together when finished.

BEDSIDE NOTES.

Name Room No. Ward No.

Date	Hour	Temp.	Pulse	Resp.	Urine	Stools	Treatment	Diet	Rem'ks.

[The remainder of this page of the chart is ruled off in columns under the above headings.]

It becomes the duty of the nurse in charge to fill in the bedside notes, to copy, from slips furnished by a member of the house staff, the results of the urine and blood examinations, to fill in the space recording any operation and its results; furnishing to the office, on a slip provided for the purpose, the nature of the operation that proper charge be made, also the record of any transfer from ward to room, etc. To a member of the house staff is allotted the duty of taking the history of the individual directly on the chart.

When the case is finished, the chart is returned to the office and the attending physician or surgeon is asked to enter the diagnosis and append his signature.

The chart is put away and the card which was furnished the clerk, filed in card form, as an index of the patient's name and number, or an index may be kept in a book provided for the purpose, together with another of the disease, so that either may readily be referred to.

The accompanying reproduction of the chart shows the wording, but not the space. The chart itself is 11 by 15 inches. While not claiming that either the chart or the methods employed are in any manner perfect, they are offered as a means of bringing some order out of chaos, and for suggestions as to improvements.

DISCUSSION.

Dr. E. S. Wright, Salt Lake City, said that the size of the chart is a matter of some importance in handling and one to which he would find some objection. If only that part of the sheet were used below the lower line it seems to him that it would be better. He has used a form of chart similar in width and length for recording in a private hospital. The space for diet needs to be enlarged while that for remarks may be lessened. It is a very essential matter to specialize in the dietary. These are the objections he would offer to the use of such a large sheet. He prefers to take the material on the side giving clinical history, and an independent piece of paper, say a blue print containing the clinical history, having the two uniform in size.

Dr. Harry M. Sherman, San Francisco, said that the principal objection in his mind is the fact that in these records one has to write on both sides of the sheet, and he thinks this will prove to be a very decided drawback, as it is customary when papers have to be filed together that only one side should be used. Apparently the history is not kept by the chief, but by an assistant. Dr. Sherman finds it useful to have kept with the records of each case a special sheet which is his and on which he can jot down observations himself. This always stays with the history and is bound up with it, so that when he goes back over the records of cases he can find his own individual expressions of opinion, which are much more intelligible to him than those put down by others. This sheet is of a separate color and he considers this a practical point. Another objection is having the space so ruled as only to allow a certain amount of space under each heading. Some things can not be kept in a given space, and a patient's condition may call for space which should be limited only by its own needs. He considers that in this respect the chart is a little too mechanical.

Dr. G. A. Wilson declared that Dr. Wright's objections are good. These charts are not kept at the patient's bedside, but in a separate room, and the top of the chart is grasped by a clip. The difficulty of writing on either side is important, and a great objection is that the house surgeon, when taking the history of the case, often soils the sheet. Dr. Wilson said that Dr. Sherman evidently must have reformed, as they were in Bellevue Hospital together and he used to have an old convalescent take his histories for him, but now, apparently, he takes them himself. Dr. Wilson said that he did not present the chart as a perfect specimen, but only to get suggestions. He has often been annoyed and embarrassed when he wanted a history and it could not be found.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

SATURDAY, SEPTEMBER 23, 1905.

THE INDIVIDUAL AS A FACTOR IN INFECTIOUS DISEASES.

One of the characteristics of medical opinion which can be traced through the literature of all ages is its tendency to run to extremes. From a period of excessive bleeding and purging we react to a period of practically no bleeding and mild purging, and instances of a similar character could be multiplied indefinitely. Sometimes the complete abandonment of an old method or idea is due to discoveries which indicate its fallacies; more often the change is due to the influence of some one man or group of men who change the fashion, for there are fashions in medicine as well as in spring bonnets. Again, a medical theory may be so attractive and so plausible from certain points of view that, for the time being, it hypnotizes us into forgetting or minimizing the other points of view. A recent article of Ewing[1] suggests that we have been so hypnotizing ourselves with certain aspects of the bacterial theory of infectious diseases.

In bacterial infections, what we call the disease is the expression in symptoms and signs of a struggle which is taking place between the invading bacterium and the invaded individual. The general tendency of the profession, ever since bacterial diseases came into prominence in the last quarter of the preceding century, has been to lay too much stress on the rôle of the parasite, and too little on the rôle of the host, in analyzing the factors producing the disease. This tendency, though widespread, has not been universal, for there have always been those who championed the cause of the individual. We remember, for example, that Maurice Letulle, in his classical work on inflammation, suggested that we should speak of pyogenic individuals rather than pyogenic cocci.

It is in the class of infections represented by typhoid fever that we find the greatest difficulty in explaining all the changes from the point of view of bacterial action alone. The typhoid bacillus typifies a class of bacteria to which most pathogens belong, and in which the disease-producing toxins are not excreted as in diphtheria, but are set free only when the enclosing cell is damaged. Thus in typhoid fever we see at an early stage of the disease a bacteriemia, but as the disease progresses, even in unfavorable cases, the bacteria gradually disappear from the blood, and in favorable cases the disappearance is complete. In the production of immunity from diseases of this class this destruction of the causal bacteria is all-important, for it is found that immunity can not be produced by the injection of filtrates of the cultures, but that the bacterial cells must be introduced also. During the destruction of the bacteria, certain poisonous products are set free, and, though we know but little of their composition in many instances, enough has been discovered to lead one to surmise their nature and effects. Vaughan has expressed the opinion that the bacterial cell is a chemical compound of definite composition. From the colon bacillus he has isolated a variety of chemical groups, among which nuclein, amido and carbohydrate groups are most important. These substances exert an intensely irritating local reaction, and evidently produce a cumulative poisonous effect on the body cells, as apparently no real immunity to them is developed. It seems probable that, like other poisonous proteids which do not cause immunity, they must be disposed of by oxidation. During this process, and before they are completely destroyed, they may seriously injure certain organs engaged in their destruction, especially the liver, in which histologic evidence of severe damage is generally to be made out. In typhoid fever, then, taking this as an example, the bacilli not only produce toxins which can be immunized by antitoxins, but also other poisons which have a cumulative action, and which must be *destroyed by oxidation* more or less at the expense of certain internal organs. There is evidence that the changes excited in the body cells by the cumulative toxins result in serious disturbances in the metabolism of typhoid patients which lead to a condition closely resembling at times acute yellow atrophy of the liver. Once started, these degenerative processes seem, to a certain extent, to be self-perpetuating. According to this conception typhoid fever does not represent merely a specific bacterial intoxication, but shows in addition to this the effects of a peculiar, self-perpetuating autointoxication. The bacterial toxemia is the predominating factor early in the disease, while the autointoxication plays the leading part in the later stages. It is possible, by accepting this hypothesis, to understand why it is that different individuals with apparently the same degree of typhoid infection react in the end so differently. It shows us that in this and many other bacterial diseases we must reckon much more with the rôle played by the individual than we have in the past.

PHYSICAL CHEMISTRY APPLIED TO THE PHENOMENON OF AGGLUTINATION.

Every one is familiar with the phenomenon of agglutination from the point of view of a diagnostician. When blood or serum from a typhoid patient, for instance, is added in the proportion of 1:50 to a uniform suspension of typhoid bacilli, the bacteria clump together and fall to the bottom of the vessel. The explanation of this clumping has been made the subject of a large number of investigations and many interesting results have recently been presented. In the light of these studies, the phenomenon may be divided into two phases: (1) The union of agglutinin with the bacteria, and (2) the clumping and precipitation of the bacteria thus treated, which may be called "agglutinin-bacteria." Agglutinin-bacteria which have been washed in sterile distilled water and resuspended in distilled water do not undergo spontaneous agglutination as long as no salts of any kind are present in the suspension. The addition of salts, as, for example, NaCl or $CaCl_2$, even in small quantities, produces agglutination.

---

[1] Proc. of the Pathol. Soc. of Philadelphia, vol. viii, No. 3.

The first phase of the phenomenon of agglutination, i. e., the union of agglutinin with bacteria, is probably represented by a chemical reaction which results in the formation of a more or less stable compound, agglutinin-bacteria. Very little, however, is as yet known about the nature of this reaction. The second stage, that is, the clumping of the bacteria, has been likened by Bordet to the precipitation of colloidal solutions (as of $As_2 S_3$) and emulsions of unorganized substances (as of mastic or kaolin) by salts and acids. The particles in a colloidal solution and in an emulsion, and also the bacteria in a suspension of such, are charged with electricity which is shown by the fact that they migrate toward one of the poles of the battery when a current of electricity is passed through the colloid or emulsion. Bacteria in suspension, and also many colloids and emulsions, usually have a negative charge and hence migrate toward the positive pole (anode). It has been found, now, that such colloids and suspensions of bacteria are precipitated, or agglutinated, very similarly by the same salts, and that the laws governing the precipitation of colloids also govern the agglutination of bacteria.[1] Thus the power of a salt to produce precipitation of colloids, or agglutination of bacteria, is dependent on (1) the degree of its electrolytic dissociation, (2) the valency of the cation (the basic radical of the dissociated salt), (3) the speed of migration of the cation, and (4) its decomposition tension.[2] The higher the valency of the cation and the lower its decomposition tension the greater, in general, is its power to precipitate colloids and bacterial suspensions. H ions form a striking exception to this rule, presumably on account of their high speed of migration. Sodium, for instance, has a high decomposition tension and its valency is low, and in agreement with this it has been found that its salt, NaCl, precipitates colloids only when used in high concentrations, and does not agglutinate bacteria at all, unless they have previously been acted on by agglutinin. That is, agglutinin-bacteria are more susceptible to the action of NaCl than untreated bacteria. On the other hand, salts of metals with a high valency and a low decomposition tension, as $Al_2 (SO_4)_3$, precipitate untreated bacteria when only small quantities of the salt are added. The greater susceptibility of agglutinin-bacteria to the influence of the salt is a general law. All salts clump agglutinin-bacteria more readily than the untreated organisms. This fact necessitates a revision of the old conception of the rôle of agglutinin. Apparently, agglutination of bacteria is always produced by the salts in solution and not by the agglutinin. The latter serves only to render the bacteria more susceptible to the influence of the salts. In agreement with this it has been found that agglutinin-bacteria have a smaller charge of negative electricity than untreated bacteria. This is an important fact, because the agglutination by salts seems to be due to the fact that they discharge the electricity resting on the bacteria. Just how that discharge is brought about is still an open question. Billitzer[3] is of the opinion that the cation of the salt, being positively charged, attracts many bacteria, or particles of a colloid, which results in a neutralization of their charges of electricity with the simultaneous formation of a clump which falls out of suspension.

This view explains the facts very beautifully, although it would be premature to say whether or not it is the correct explanation. We can now understand, however, why a trivalent cation is more effective in producing agglutination than a bivalent one. The former has a greater charge of positive electricity than the latter and hence can neutralize the electricity of opposite sign on a larger number of bacteria. Similarly the greater ease with which agglutinin-bacteria are clumped by salts than untreated bacteria is due to the smallness of their electrical charge which is readily neutralized by the cations of even traces of salts.

AMERICAN SANITARY ACHIEVEMENTS.

In the discussions on papers on tropical diseases before the Section on Practice of Medicine, at the recent session of the Association, particular attention was called to the amount of work which has been accomplished by American sanitarians in the various tropical countries that came under the domination of our government at the time of the Spanish-American war. Cuba has been entirely freed from the scourge of yellow fever, which had existed there for four centuries and was considered to be so firmly rooted in the country that its eradication was thought to be hopeless. In Porto Rico, the characteristic anemia, which for at least a century has been sapping the life and energy of the people, has been studied as never before, its true cause recognized, and the proper treatment for it evolved, so that now there is a prospect that before many years have passed this evil, too, will be eradicated. Particular attention was called to the work of Drs. Ashford and King,[1] who have been engaged in a field campaign against uncinariasis in Porto Rico for several years and who have the best hope of success in wiping it out. This will be the first time in the history of medicine that a disease affecting practically a whole people and easily transmissible has been successfully combated.

---

[1] Neisser and Wechsberg, Münch. med. Wochft., 1904: Bechhold, Zeitschr. f. phys. Chemie, vol. 48.

[2] The term "decomposition tension" refers to the electrical tension which must exist on the electrodes to deposit the metal from aqueous solutions of its salts. It is a measure of the affinity of the metal for its electrical charge.

[3] Sitzungsber. d. Kais. Akad d. Wiss. in Wien, vol. cxiii, p. 1159.

[1] THE JOURNAL A. M. A., Feb. 11, 1905, p. 478.

The straightforward, enterprising methods of American medical investigators recall so typically what has been accomplished in all lines of work by our countrymen that we can scarcely fail to be especially proud of their success. If the Spanish-American war brought no other benefits in its train than those of the saving of life and suffering from yellow fever in Cuba and from uncinariasis in Porto Rico, it would have been well worth the cost of men and money it occasioned. As a matter of fact, however, the benefits conferred on acquired territory have been reflected *in the sanitation of* our own states. The compensation that always comes to the charity worker in benefit to himself has not been lacking in this national charity. While the anemia of Porto Rico was considered to be specific to the island, the discovery of its intestinal parasitic cause has led to more careful observations with regard to the etiology of obscure anemic conditions, especially among children in our southern states and the consequent discovery of the same parasite there.

What has been accomplished in advance in knowledge with regard to the distribution of this parasite and the mode of infection in the South shows the same enterprising spirit present among the medical investigators in that part of the country and makes an encouraging prospect for the future of medical progress all over the United States. Dr. Claude Smith's[2] investigations apparently confirm the assumption that these intestinal parasites gain an entrance into the body through the skin, and that it is the habit of going barefoot that causes infection and reinfection until large numbers of parasites may gather on the intestinal mucous membrane.

The work which has been accomplished in Cuba and in Porto Rico is only an introduction to the success of American sanitation in the Philippine Islands. Dr. Musgrave's paper,[3] presented to the Section on Practice of Medicine at this session of the American Medical Association, shows that the mysterious problems of amebic dysentery which have been so long under discussion are gradually nearing their solution as the result of careful investigation. Not only have the doubts about the etiology been cleared up, but the fact that a long latent period at the beginning of the disease frequently occurs, and that this may be followed by severe and even fatal infection, with fulminant symptoms lasting only a few days, shows the danger of the disease and the necessity for microscopic investigation for its diagnosis. There is, perhaps, no original work on intestinal parasites of recent years of more value than these studies of amebic dysentery.

Recently the lay press of the country has indulged in frequent expressions of discouragement with regard to the possibility of American medical science managing successfully the inevitable sanitary problems in the construction of the Panama canal. If those who are distrustfully pessimistic will but recall what has been accomplished in the last few years, apparently in the face of insuperable difficulties, a more hopeful spirit will very soon result.

If, with the comparatively inadequate resources and men of the Marine-Hospital Service and other sanitary bureaus so much has been accomplished in the recent past, it is easy to understand how much might be done if abundant opportunities were afforded and resources were only limited by the judgment, not of politicians, but of expert sanitarians.

MASTICATION AND CHILDREN'S HEALTH.

Two pathologic conditions are observed with increasing frequency among the children of this generation after the age of 2 years. They are an enlargement of the cervical glands, as well as of the adenoid tissue within the pharynx, and the occurrence of carious teeth. Among the school children of our large cities, according to medical school inspectors, about one in five, at least, will be found to have glandular enlargements in the cervical region, either anteriorly or posteriorly. Something more than one in ten will be found to be a mouth-breather, because of overgrowth of the adenoid tissue at the back of the mouth. Nearly one in four will be found to be suffering from marked deterioration of the teeth that causes interference with mastication and at the same time proves a fruitful culture medium for micro-organisms of various kinds which are sure to do harm in the lower digestive tract. Recent discussions among dentists call attention to the fact that to a noteworthy extent all of these pathologic conditions in and around the mouths of children may be traced to certain bad habits in the matter of feeding that have been introduced in recent years.

It is the present custom to advise that children shall be fed almost entirely during the second and third years on soft food that is practically liquid in character. Eggs are especially recommended, though milk still constitutes the basis of the diet. Breadstuffs are taken usually after having been soaked or, if not, care is exercised in furnishing the children only with the softer portions of bread. Very few children fail to like crusts if they are tempted to eat them when first allowed starchy materials, but after a time it is rather a difficult matter to tempt them to eat the harder portions of bread at all. Puddings that are given to children are, of course, all soft, and, as meat is practically tabooed, the children's teeth have no proper exercise of the function for which they exist, and without function no organ in the body develops properly or remains long in a normal healthy condition.

---

[2] The Journal A. M. A., Aug. 27, 1904, p. 592.
[3] The Journal A. M. A., Sept. 16, 1905.

It was very evidently Nature's intention that some chewing should be done almost as soon as the teeth begin to appear. The child erupts its incisor teeth just about the time that the decreasing milk supply in the mother suggests the necessity for additions of some kind to its diet. After the appearance of upper and lower incisor teeth, suckling usually becomes increasingly difficult, because the child's tendency to chew at something makes the operation uncomfortable for the mother. As pointed out by Dr. J. Sim Wallace,[1] this used to be the signal in past generations for the provision of various materials that needed to be masticated before they could be swallowed. After all, the habit of keeping cows is comparatively modern, and the children of the generations before that of the cow-keeping time had to be supplied with food without this precious adjunct to the child's dietary, which now, it would seem, is likely to be abused because of the readiness with which it can be obtained.

The child's gastrointestinal organs have accommodated themselves very well to the change of diet that has come with advancing civilization. In and around the mouth, however, most pathologic conditions can be traced to the lack of mastication. The lower jaw particularly loses in development because of the failure to exercise its function of crushing food, and as a consequence there is not room enough for the teeth. The crowding of the teeth leads to their decay sooner than would otherwise be the case, and, besides, the best possible cleansing of the teeth comes from the thorough mastication of the food. In the country districts of the poorer countries especially the teeth are excellent all during life as the result of Nature's care for them under the simpler conditions of life. When children are fed entirely on liquid diet, there is, as can easily be understood, none of that cleansing friction that comes from mastication. Once decomposing food has succeeded in bringing decomposition to the teeth themselves, there is the likelihood of infectious agents finding their way into the tissues and causing enlargements of the cervical glands. Nearly always anterior cervical glandular swelling is associated with bad teeth.

The lack of exercise of the jaws leading to deficient development affects also the posterior portion of the mouth and the pharynx. Instead of the effort needed to swallow a material that has been chewed, liquid material flows easily down the throat, and as a consequence there is likely to be an overgrowth of the succulent tissues that would ordinarily be kept in healthy tone by the exercise of the swallowing function and the stimulating friction of the passing bolus. To some extent at least this explains the enlargement of the pharyngeal adenoid tissue, and occasionally too of the tonsils, though probably in the latter case the accessory action of infective agents from decaying teeth is of importance. In a word, a vicious circle of pathologic conditions is formed as a consequence of the lack of proper exercise of the function of mastication. Now that the heated term, with its danger for children in their second summer, is past, it seems wise to recall attention to the benefit likely to accrue from the careful following of Nature in this matter of mastication rather than the too artificial standards of the dietary of an overcivilized period.

A CREDIT TO NEWSPAPERS.

Having in mind the entire dependence of the quacks and nostrum makers for their success on their alliance with the newspapers, and the ready acceptance by most papers of money received from those who murder the unborn as well as from those who plunder the invalid, the medical profession universally feels that the press, in the main, is by no means eager to stop those particular and vicious forms of graft that it finds profitable. Now that genuine effort is at last being made to expose to the world this newspaper graft, the profession will do all it can to support the effort to break up that alliance with the press that alone enables the nostrum vender to become rich by palming off whisky as medicine and morphin as a harmless remedy. In so doing, however, we must not lose sight of the good deeds of journalism. Our quarrel is not with the press, but with one of its actions. Much to the credit of American newspapers of all degrees, whether the metropolitan daily or the hamlet weekly, is their attitude toward the new etiology of yellow fever. Looking over the editorial comments on the New Orleans epidemic made by dozens of newspapers, one is struck by the well nigh universal acceptance of the mosquito theory. A well-established advance in medical knowledge has never been more readily received, nor its teaching more heartily supported. This has resulted in large part from the wise action of the United States Public Health and Marine-Hospital Service in sending out to the press a bulletin recounting in detail the work and experiments of Major Walter Reed in Cuba. Nevertheless, the frank confidence and ready receptivity of the press are most noteworthy and pleasing. It is true that here and there is found a discordant note of unprogressive conservatism, but the proportion is no greater than exists within our own medically trained ranks. The beneficial result to the public health of this hearty support of the press being so very great, the medical profession extends to the newspapers its profound gratitude.

THE CAUSATION OF ARTERIOSCLEROSIS.

The continuance of life depends primarily on the provision, through the blood, of sufficient nutriment of proper character for all of the tissues and organs of the body. Deficiency in either quantity or quality will result at first in derangement of function and ultimately, if maintained, in alterations in structure. Tissues of highest organization will naturally suffer earliest and in greatest degree. The blood vessels are likely to be involved in the morbid process, in part directly from the irritating effects of circulating noxious matters, in part indirectly through the imperfect nutrient supply conveyed by the vasa vasorum. The result will be some form of vascular degeneration, namely, atheroma followed by calcification, or sclerosis, or hypermyotrophy, or a combination of several or all. Arteriosclerosis is a common association of chronic nephritis, of which, it appears, it may be cause or effect or concomitant. Old age, excessive muscular activity and various infectious and toxic processes are also to be considered among the etiologic factors. From a review of current theories regarding the causation of arteriosclerosis, Dr. John M. Cowan[1] concludes that arterial damage may result from many and varied causes. Continued high blood pressure in time invariably affects the vessels, and this is one of the most important causes of widespread disease of the blood vessels. High blood pressure may be secondary to renal lesions or it may originate without any disturbance on the part of the kidneys. Under the latter circumstances it is to be attributed to some derangement of the alimentary tract. Excess, relative or absolute, of food stuffs or of alcohol, intestinal fermentation or putrefaction, hepatic, pancreatic or gastrointestinal insufficiency may thus all be the initial fault. The arteries may be damaged as the result of various intoxications. Metallic poisons—lead, mercury, etc.—comprise one group; bacterial toxins—rheumatism, enteric fever, etc.—another. Bacteria themselves may be present in early lesions. Syphilis is a common cause of local lesions. Severe continued physical activity, however it may act, is probably also a causal factor.

---

PUBLIC INTEREST IN RESEARCH.

The public interest in research and in scientific knowledge of various kinds has a deep significance that augurs well for the future. Mutual understanding between the lay public and scientific men is a highly important and desirable condition. Prof. John M. Coulter,[2] in discussing this subject, makes the following statements: Matter describing scientific research that is now published in popular magazines and in newspapers is scant in amount, sensational in form and usually wide of the mark. There is an increasing desire on the part of the public for information on these subjects. The usual method of presentation is through a middleman, a reporter, who presents the matter in a "popular way," and in so doing makes misleading statements and almost entirely removes the scientific atmosphere. The important need in the situation is for the scientific men themselves to study the popular method of presentation and to provide matter which is at once scientifically correct and interesting to the public. Professor Coulter appears to us to have summarized the situation very well. He calls attention very pointedly to the common misconception of the practical nature of research. When a scientific man brings out a discovery which is of marked commercial value, the laity is apt to comment on the commendable transferal of the investigator's energy from some useless laboratory experiments to a field of practical value. In this there is disregard of the fact that the so-called practical discovery is based on and is the result of, in many cases, years of laborious and patient study, which had been considered by the average layman pure waste of time. Professor Coulter urges that interesting scientific articles by competent men will show research to be practical, will secure endowment for further research, and will secure harmonious co-operation between the various persons interested.

REFORM IN CHARITABLE INSTITUTIONS.

Events in many parts of the country indicate the increasing interest of the medical profession in the conduct of charitable institutions. As organization becomes steadily more complete we are certain to exercise an increasing influence in this direction. A few months ago The Journal[1] suggested that each State Medical Association create a committee whose duty it should be to keep close and conscientious watch over the eleemosynary institutions of the state, having an eye particularly to securing scientific medical care for the inmates and graft-free administration. In more than one state this suggestion has been well received. President Halderman of the Ohio State Medical Association in his annual address strongly recommended the appointment of such a committee. Of course the "machine" politicians everywhere have medical friends through whom may be expected subtle efforts to keep the attention of physicians away from these "sores." The interest of the profession in this matter, however, is so direct and so great that its progress will not be stayed. In Illinois, reform from another source has just dawned in the appointment by Governor Deneen of the new Civil Service Commission. The character and past record of the appointees ensures genuine civil service among the employes of the charitable institutions of the state. The commission at its first meeting outlined a program of careful investigation and of practical execution of the new law. Their efforts to bring the Illinois institutions up to a high level of honesty and efficiency will be closely observed and heartily supported by the medical profession.

ANOTHER SETBACK FOR THE ALCOHOLIC NOSTRUMS.

These are busy times for the manufacturers of the alcoholic nostrums. Two powerful lay publications are conducting a steady and winning campaign against the use of these "hypocritical cocktails," and now the United States government has taken a hand. The Commissioner of Internal Revenue, John W. Yerkes, on September 12, officially notified collectors of internal revenue that, after Dec. 1, 1905, the manufacturers of these compounds will be called on to pay the special tax for rectifiers and liquor dealers, while the retailer must pay the special tax for liquor dealers. The ruling holds that the tax must be paid by manufacturers of every compound in which any added drugs are in such small quantity as to have no appreciable effect on the alcoholic liquor of which the preparation is largely composed. It is further held that the tax applies to "remedies" in which the added drugs, no matter what their quantity, are not of a nature to impart any medicinal character to the alcoholic liquor. When the contained drugs really are medicinal no tax will be demanded. In deciding individual cases under this ruling the manufacturer's formula will not be accepted as final. There will be a chemical examination of samples bought in the open market and analyzed in the Washington laboratories. It will thus be seen that each nostrum will come up for interpretation of its character and that discretion will be observed in the classification of any particular compound. It is earnestly to be hoped that publicity will be given to the analyses and decisions in each case, for the workings of this new ruling will be very interesting both to the profession and to the general public. If this interpretation of the statute is strictly enforced it will be a decided help in the effort to protect people from one of the most dangerous classes of popular nostrums. If it results in drawing on druggists the attention of state revenue officers and anti-saloon league workers more than heretofore has been the case, great good will come. In spite of all this assistance, however, we must not abandon the agitation to have Congress, by statute, require, under severe penalty, that every nostrum label shall state truthfully the contents of the bottle.

---

[1] The Journal, March 11, 1905, p. 796.

Medical News

ILLINOIS.

Personal.—Dr. John G. Franken, Chandlerville, is slowly recovering from injuries recently sustained in a runaway accident.——Dr. Roy F. Rogers, Shelbyville, has returned from his trip to Europe.

Hospital Under Way.—The Taylorville Hospital Association has already raised $6,218 toward its building fund, and by October 1 the entire amount required of $10,000 is expected to be raised. Bids for construction of the hospital were opened September 20.

Case Against Physicians Failed.—In the damage suit brought by George Gillogly of Mount Carroll against Drs. Firestone, Karcher and Bushnell, Freeport, for alleged malpractice, the plaintiff did not make out his case and the judges entered an order to dismiss the suit.

Municipal Control of Milk Supply.—At a receent meeting of the Sangamon County Medical Society resolutions were adopted favoring the municipal control of the milk supply of Springfield, which, it was stated, is absolutely necessary in order to preserve the life and health of all, especially children and invalids.

County Hospital Examination.—Examinations of candidates for positions on the resident staff of Cook County Hospital will begin in Chicago September 28. Those who pass will be placed on the civil service eligible list and will be assigned places on the staff when vacancies occur. Dr. Fernand Henrotin is chairman of the examining board.

Endowment Conditions Changed.—A permanent hospital building for Canton is assured as the Misses Graham have agreed to purchase a site and erect a building to cost about $15,000 and to accept as an endowment fund the amount already raised by public susbscription (about $10,000), instead of $20,000, as provided in the original agreement.

Chicago.

Cocain Seller Fined.—Paul Zito, proprietor of two drug stores, and Joseph Moell, a clerk employed in one of these stores, were each fined $100 and costs for selling cocain; both have appealed.

Health Laboratory at Last at Rest.—After having received seven orders to vacate its quarters in the City Hall, after having six times succeeded in getting the order revoked, and after having secured locations in at least two other buildings, the laboratory of the health department has finally moved from the fourth floor of the City Hall to the Galbraith building, Madison and Franklin streets.

Unlicensed Practitioners in Trouble.—On September 13 Fred L. Orsinger was fined $200 and costs, and Anna Brickler $100 and costs for practicing medicine without license. The prosecution was undertaken by the State Board of Health.——Mrs. Barbara Bolle, who was accused of practicing medicine without a license and who failed to appear when the case was called, was sent to the county jail September 15, where she will be held for 90 days unless the judgment of $200 entered against her is paid.

Deaths of the Week.—During the week ended September 16, 514 deaths were reported, equivalent to an annual death rate of 13.46 per 1,000; 14 more deaths occurred than in the previous week, and 71 more deaths than in the corresponding week of 1904. Among the principal causes of death were: Acute intestinal disease, 113; consumption, 55; heart diseases, 48; violence, including suicide, 39; pneumonia and nephritis, each 34, and cancer, 26. The increase in mortality as compared with last year is 7.8 per cent., is due almost entirely to the increased prevalence of acute intestinal diseases among children under 5 years of age, caused by the frequent heavy rainfalls, followed by relatively high temperature for this season.

Personal.—Dr. O. P. Johnstone, fellow in pathology at Rush Medical College, has been appointed to the chair of pathology in the University of Colorado, Boulder.——Dr. Robert H. Babcock has returned from his summer home in Green Lake.——Dr. Henry Carey, late interne at Wesley Hospital, has been appointed a member of the staff of the Michigan State Hospital, Kalamazoo.——Dr. George F. Butler, professor of materia medica, therapeutics and clinical medicine in the College of Physicians and Surgeons, has resigned.——Dr. and Mrs. Julien E. Hequembourg have returned from the Pacific coast.——Dr. Nicholas Senn has been reappointed surgeon-general of Illinois, with the rank of colonel.——Dr. and Mrs. Oscar J. Price have returned from Europe.——Dr. and Mrs. E. C. Dudley have returned after a summer in Wyoming.——Dr. Edmund J. Doering spent the summer in the Catskill Mountains

INDIANA.

Dr. Thomas Acquitted.—Dr. William T. Thomas, Marion, who was arrested August 25, charged with a criminal operation on Ida Gaston, who died in Indianapolis the day before, was acquitted August 31, the judge stating that no evidence against Dr. Thomas existed.

Medical Society Library.—The Vigo County Medical Society has appointed a committee consisting of Drs. Knowlton, Julius R. Young and Bennet V. Caffee, to consider the advisability of establishing a medical library, space for which is expected to be obtained in the Emeline Fairbanks Library, Terre Haute.

Old Physicians.—Dr. William H. Wishard, Indianapolis, thought to be the oldest practicing physician in Indiana, is now nearly 90 years old and still answers professional calls.——Dr. Hubbard M. Smith, Vincennes, poet, historian and physician, celebrated his eighty-fifth birthday anniversary September 6.

Personal.—Dr. George D. Kahlo, Indianapolis, has returned from Europe.——Dr. Austin Funk, New Albany, sailed September 6 on the *Oceanic* for England.——Dr. B. H. B. Grayston and family, Huntington, have returned from an extensive western trip.——Dr. William H. Smith, Rushville, underwent an operation at the Ricketts Hospital, Cincinnati, and is reported to be making favorable progress toward recovery.

Knox Count Hospital.—At a meeting of the Knox County Council at Vincennes September 5, an appropriation of $25,000 was made for the erection of the county hospital. A site has been secured in South, Vincennes, which has been deeded to the county on the condition that it should appropriate enough money for the erection of the building. The Clark-Gibault Hospital Association will turn over about $5,000 to the fund. It is probable that work on the building will begin at once. It is expected to cost $50,000.

Madison Gets Hospital.—Madison has been selected as the location for the new Southeastern Hospital for the Insane. A tract of land has been accepted comprising about 393 acres on a site 346 feet above the level of the Ohio River. The provisions under which the site was accepted are as follows: That good water will be furnished the institution in sufficient quantity; that the commission will be given privilege of selecting whatever portion of the land offered it desires; that the price for the land be less than was originally specified; that the Pennsylvania Railroad construct switches to connect with the institution; that the title of the land shall be approved by the attorney-general; that streets leading to the proposed site of the hospital be improved by the city, and that the site shall be given to the commission within a specified time.

KANSAS.

Hospital Dedicated.—St. Mary's Hospital, Winfield, was formally dedicated September 3 by Bishop Hennessy of Wichita. The hospital has thirty rooms and is equipped with modern conveniences and appliances.

Personal.—Dr. D. W. Manson, Burlington, left on August 28 for Central America.——Dr. G. H. Hoxie, dean of the Kansas University School of Medicine, has removed to Kansas City.——Dr. W. F. Kuhn, El Dorado, has been appointed superintendent of State Hospital No. 4, Nevada, Mo.

Fever in State Hospital.—Typhoid fever has developed at the Topeka State Hospital for the Insane. Five employes and one inmate are ill with the disease. The superintendent believes that the ice supply of the institution, which is obtained from the Kansas River, is responsible for the epidemic.

Kansas University Hospital.—A contract has been awarded for the erection of the medical pavilion, which is to be the first building of the Eleanor Taylor Bell Memorial Hospital at Rosedale. It is proposed to build the other four buildings, one each year. The next building to be constructed will be the surgical pavilion; the third an isolation ward, and the other two will be ward buildings for general patients, all buildings being grouped around the central medical pavilion. The latter will accommodate forty patients.

LOUISIANA.

Personal.—Dr. Clarence Pierson, Alexandria, has been appointed superintendent of the Insane Asylum of the State of Louisiana, Jackson.

Physicians Take Outing.—Through the courtesy of the board of park commissioners, Dr. Rudolph Matas entertained on September 10, on board the tug *Samson*, Dr. White, United States Public Health and Marine-Hospital Service; Professor Boyce, the English scientist, and others.

Presentation to Dr. Hays.—On August 31 the employés of the Insane Hospital of the State of Louisiana, Jackson, presented Dr. George A. B. Hays, late superintendent of the institution, with a handsome silver loving-cup. Dr. Hays left September 1 for Alexandria to take charge of the new state hospital near Pineville.

MAINE.

Personal.—Dr. Eben Alden and wife, Rockland, are spending the summer in Europe.——Dr. John T. Dilling, Sprague's Mills, was seriously scalded about the face, hand and arm, and also inhaled steam, in a railway accident at Gardiner.

Hospital Notes.—A gift of $4,000 has been received for the Maine Sanitarium, Portland.——The Bar Harbor Medical and Surgical Hospital has been enlarged to twice its former size, at a cost of about $10,000.——The Japanese envoys have endowed two beds in the York Hospital.

Promises to Reform.—Theophilus Neilson of New York City, who owns a summer cottage in York Harbor, and has been practicing osteopathy there, was arrested August 24 on a warrant sworn out by Dr. William J. Maybury, Saco, secretary of the Maine Medical Registration Board, charged with violating the medical registration law. On his agreeing to discontinue the use of the prefix "Dr." he was allowed to go on his own recognizances.

Maine's Vital Statistics.—During 1904 the state registrar of vital statistics reports 11,009 deaths, 336 more than for the previous year, and 15,130 births, or 36 less than for the preceding year. The death causes which show an increase for the year are: Influenza, 74; nervous diseases, 70; diarrheal diseases, 68; typhoid fever, 63; nephritis, 62; whooping cough, 59; heart diseases, 56; rheumatism, 13; pneumonia, 12; diabetes, 9; measles, 8, and scarlet fever, 5. A decrease in deaths was noted in: Tuberculosis, 89; bronchitis, 32; peritonitis, 26, and cancer, 17.

MARYLAND.

Union of Schools.—A movement has been set on foot for a union of the schools of the University of Maryland, St. John's College, Annapolis, and the Maryland Agricultural College into a state university. A committee has been appointed to draw up a plan, of which Dr. Randolph Winslow is the representative from the School of Medicine of the University of Maryland.

Hospital Work Begins.—The Washington County Hospital Association has begun operations at Hagerstown on a moderate scale under Miss M. Grace Matthew, a trained nurse. At a meeting of the county medical society September 14 Mr. Edward W. Mealey, its benefactor, explained its plans and scope. At present only accidents, acute and subacute cases are admitted.

Faculty Meeting.—The one hundred and seventh semi-annual meeting of the Medical and Chirurgical Faculty of Maryland will be held at Deer Park, September 21 and 22. Matters to be brought before the next legislature, which convenes in January, will be brought before the house of delegates, especially a new medical practice act, new laws governing medical inspection in the counties, and a law regulating the practice of midwifery. The annual address will be delivered September 22 by Dr. Charles A. L. Reed of Cincinnati on "The American Family." Dr. W. S. Thayer, Baltimore, will also deliver an address on "Some Public Duties of the Physician." There will be a series of brief reviews of recent medical progress by Drs. Thomas B. Futcher, Frank Martin, Guy LeR. Hunner, and Frank D. Sanger, all of Baltimore; Dr. Harvey W. Cushing, Baltimore, will speak of palliative operations in intracerebral tumors; Dr. Frank J. Kirby, Baltimore, on thyroid tumors; Dr. Henry O. Reik, Baltimore, on eight cases of lateral sinus thrombosis and the advisability of ligating the internal jugular vein before opening the sinus, and Dr. James M. H. Rowland, Baltimore, on artificial interruption of pregnancy in toxemia, time and methods. The Allegany and Garrett county medical societies will entertain the members of the Faculty on the afternoon of September 22 with drives over the mountains.

Baltimore.

Typhoid.—The number of reported cases of typhoid fever for the week ended September 16 was 34, a decided decrease; deaths from the same disease, 9.

Library to Be Made Useful.—The library of the College of Physicians is to be put on a working basis. A librarian has been appointed and several hundred volumes have been collected.

Personal.—Dr. William Hewson Baltzell, now in Paris, will spend the winter in India.——Dr. Edwin Geer, commander of the Maryland Naval Reserves and surgeon of the fire department, while attempting to board a car on September 6 fell and was severely injured about the nose and face.——Dr. Edward J. Bernstein has removed to Kalamazoo, Mich., and Dr. Milton R. Walter to Chicago. Both have been connected heretofore with the University of Maryland Medical School.

MASSACHUSETTS.

Embalmers' Board Established.—Under the new state law a board of embalming has been established. Henceforth every undertaker who practices embalming must have a license, for which he must pay $5. Those in practice three years are passed, while future applicants must pass an examination by this board.

Boston Death and Disease.—For the ten weeks ended September 9 there were reported to the Boston Board of Health 2,246 deaths, as against 1,962 during the same period in 1904, and an average annual death rate of 18.50 per 1,000. Of these deaths 645 were of infants under one year, 836 of children under 5, and 406 of individuals over 60 years. There were 222 cases of diphtheria, with 15 deaths; 81 of scarlet fever, with 2 deaths; 219 of typhoid fever, with 28 deaths; 148 of measles, with 6 deaths; 403 of tuberculosis, and 215 deaths; 114 deaths from pneumonia, 11 from whooping cough, 186 from heart disease, 30 from bronchitis, and 77 from marasmus.

Good Work of Floating Hospital.—The Boston Floating Hospital's season of ten weeks ended September 13. During this time 279 patients were cared for in the four permanent wards, with 90 deaths; 90 were discharged well, 71 relieved and 28 not relieved. Of the 90 deaths 26 occurred within forty-eight hours after admission. On the last day 11 patients were transferred to the New England Hospital for Women and Children and 5 to the Children's Hospital. In the open ward, upper deck, 686 patients were cared for from 9 a. m. to 4 p. m. They made 2,374 trips, an average of 47 per day. Diplomas were given to the graduate house officers, Drs. Alpha R Sawyer and Alexander O. Fasser, to the externe in charge of day patients, Dr. W. A. Dutcher, and to 23 nurses who successfully completed the postgraduate course in the hospital.

MICHIGAN.

Large Endowment for Hospital.—By the will of the late Mrs. Julia E. Hackley, Muskegon, $300,000 is devised to the Hackley Hospital, Muskegon.

Hospital Note.—The Northern Michigan Hospital, Calumet, will be reopened about the end of September, on the return of

Dr. Charles J. Sorsen from Germany.——Dr. Peter J. Noer, formerly of Menominee, has completed a hospital building at Wabeno at a cost of $15,000.

May Be "Read Out" in Meeting.—The secretary of the Pontiac Medical Society has been ordered to keep a scrapbook in which he will paste all press notices regarding members of the society. These notices are to be read at the monthly meetings and explanations from the advertised members will then be in order.

Settlement of Contagious Disease Expenses.—Judge Perkins, Grand Rapids, rendered a decision September 7 in the Circuit Court, which defines what portion of the expense incurred from dangerous contagious diseases shall be borne by the county and what by the immediate community in which the infection exists. He holds that the expense of investigation preliminary to determining the nature of the disease, isolation, quarantine, disinfection, fumigation, or any service performed for the good of the general public, must be paid by the board of health, while expenses for medical attendance and nursing are chargeable to the county.

July and August Mortality.—During July the number of deaths reported was 2,482, an increase of 88 over June, and during August, 2,797, an increase of 315 over the preceding month. The respective death rates for July and August were 11.5 and 12.9 per 1,000. The deaths of infants under one year numbered 506 in July and 687 in August; of children from 1 to 4 years, 166 in July and 236 in August, and of individuals over 65, 678 in July and 702 in August. Almost the entire increase in mortality in August was due to the high mortality among children under 5 years of age. The more important causes of death were as follows: Tuberculosis, 196 in July and 203 in August; typhoid fever, 45 in July and 59 in August; diphtheria, 32 in July and 22 in August; measles, 10 in July and 4 in August; whooping cough, 15 in July and 19 in August; pneumonia, 65 in July and 51 in August; diarrheal diseases of infants, 204 in July and 422 in August; accidents and violence, 214 in July and 231 in August; cancer, 143 in July and 141 in August, and smallpox, 4 in July and 6 in August. Eight deaths were reported from tetanus in July, and seven of these were ascribed to the toy pistol. Two deaths from tetanus were reported in August.

Personal.—Dr. Francis H. Callow, Mount Morris, returned from England August 12.——Dr. Henry J. Hartz, Detroit, has been appointed a member of the board of trustees of the State Sanitarium for Tuberculosis.——Dr. John V. Frazier, Lapeer, has been appointed first lieutenant and assistant surgeon, M. N. G., and assigned to the Third Infantry.——Dr. Joseph B. Whinery, Grand Rapids, has been appointed a member of the Board of Health.——Dr. Thomas M. Koon, Grand Rapids, has been re-elected health officer at a salary of $1,800.——Dr. Ralph C. Apted has been appointed city physician of Grand Rapids at a salary of $1,800.——Dr. Frank B. Gray, Clare, has been appointed a member of the board of establishment and control of the state sanitarium for consumptives.——Dr. William L. Bishop, Bay City, has moved to Salt Lake City, Utah.——Dr. Alexander McK. Campbell, Grand Rapids, has been elected president of the Board of Health and Poor Commissioners.——Dr. Clarence L. Gorsline, Battle Creek, was operated on for appendicitis September 13.——Dr. Alexander Magill, Midland, who is moving to Bay City, was presented by the Midland County Medical Society, of which he is president, with a gold-headed cane, suitably engraved, at a banquet given in his honor September 7.

MISSISSIPPI.

Appropriation for Hospital.—The city council of Greenville has appropriated $3,000, to be paid in December to the King's Daughters' Hospital.

Illegal Sale of Cocain.—A druggist in Greenville was recently fined the maximum amount of $500 and six months in jail for selling cocain regardless of the statute, which forbids its sale except on prescription of a licensed druggist. This particular individual was said to have sold from $10 to $12 worth of cocain a day.

Amendment to Charter.—The Jackson Hospital Company, a corporation with its domicile in Jackson, has petitioned that its name be changed to the Jackson Sanitarium and Training School for Nurses, and that its charter shall be so amended as to give the corporation the additional power and authority to conduct the training school for nurses.

Personal.—Dr. John R. Tackett, Meridian, a member of the executive committee of the State Board of Health, is assisting Dr. John F. Hunter, secretary of the board, with the executive work of his office.——Dr. Percy W. Toombs has been appointed health officer of Greenville.——Dr. Walter Merritt, Jackson, has been elected third assistant physician of the State Insane Hospital, Jackson.——Dr. Harry H. Harrison, Jackson, has been appointed a member of the State Board of Health; Dr. Osborn M. Turner, president of the Jackson Sanatorium, and Dr. Ethelbert H. Galloway, city physician of Jackson, all vice Dr. John H. Rhodes, deceased.——Dr. Samuel H. McLean has been elected vice-president and Dr. Ethelbert H. Galloway, secretary, of the Jackson Sanatorium.

MISSOURI.

Personal.—Dr. Claude C. Crowley has been elected president, and Dr. Robert Sevier, clerk, of the Richmond Board of Health. Drs. Charles B. Shotwell and Elmer T. McGaugh are the other members of the board.

Typhoid at State University.—Typhoid fever is reported as epidemic at the State University, Columbia. Since the beginning of the epidemic seventy-one cases have been reported, with one death.

Doctor Released.—In the case of Dr. Elizabeth Short, Kansas City, charged by the coroner with having performed a criminal operation on Mrs. Louise O'Leary from the effects of which she died, the defendant was discharged August 19 because of lack of sufficient evidence.

Mount Vernon Gets Sanatorium.—At the meeting of the board of commissioners in St. Louis September 4, Mount Vernon was selected as the location of the new Missouri State Sanatorium for the Treatment of Incipient Pulmonary Tuberculosis. Mount Vernon's offer included a site of 165 acres, valued at $8,500, a bonus of $7,000 in cash, water and electric lights free of charge to the state for five years, and free telephone service.

Personal.—Dr. Frederick L. Deck, St. Louis, has returned from a trip to Japan.——Dr. Ira C. Young, St. Louis, has been appointed lecturer on orthopedic surgery at the St. Louis College of Physicians and Surgeons.——Dr. and Mrs. John A. James, St. Louis, have returned from Europe.——Dr. George James P. McNeil, house surgeon at the M. K. & T. Hospital, Sedalia, returned August 31 from Europe.——Dr. Frank S. Vernon, Charleston, has been re-elected physician at State Hospital No. 4, Charleston, for a term of two years.——Dr. Emil H. Henckler, vaccine physician, St. Louis health department, was appointed physcian-in-charge of the North End Dispensary September 1, succeeding Dr. Franz J. T. Specht, resigned.

St. Joseph.

Asylum Pavilion Opened.—The new Carey building, a pavilion for women at State Hospital No. 2, was formally opened September 6.

Gift to Library.—Dr. Jacob Geiger has presented to the library of the Medical Department of the St. Louis University a complete set of Virchow's archives, comprising 170 volumes.

Personal.—Dr. Louis J. Dandurant has had conferred on him the degree of master of arts by the faculty of Conception (Mo.) College, August 25.——Dr. Peter J. Kirschner was admitted to State Hospital No. 2, August 31 as a private patient.——Dr. Samuel F. Kessler was elected president, and Dr. Luther A. Todd, secretary, of the Northwest Missouri anatomical board, organized under the state law for the purpose of securing subjects for dissecting purposes for the local medical college.

NEW JERSEY.

Agree Not to Accept Contract Work.—"Every physician in Trenton has signed an agreement not to accept contract lodge work in any form," says the August number of the *Pennsylvania Medical Journal.*

Personal.—Dr. Wesley R. Wales, Cape May, who was indicted in the United States District Court for misapplying $16,000 funds of the First National Bank of Cape May, was acquitted September 16 after the jury had deliberated only fifteen minutes.

Sanitary Milk Plant for Camden.—Stimulated by the results achieved by sanitary milk plants in the neighboring cities, the city of Camden started a movement to establish a similar plant in that city. The subject was first considered by the Camden City Medical Society. The public records of Camden show that the death rate of children under 5 years of age during the past twelve months exceeded 36 per cent. of the whole number born during the same period. The bacteriologic examinations of the Camden milk supply show that a large number of the deaths are among children, due to milk contamination. A company has been organized with medical men at its head. The officers are as follows: President, Dr. Alexander McAlister; vice-president, Dr. A. Haines Lippincott; secretary, Dr. Howard F. Palm; treasurer, M. F. Ivins; counsel, Thomas P. Hurley; chemist, Paul H. Langner, and veterinary inspector, Dr. J. O. George.

NEW YORK.

Donation to Hospital.—The Brooks Memorial Hospital, Dunkirk, has received a first-class hot-water system costing $2,000 through the generosity of Mr. M. L. Hinman.

Buffalo Personals.—City Bacteriologist William G. Bissell has been delegated to represent the health department at the American Public Health Association.——Dr. Charles Cary is taking an automobile trip through the eastern states.

Loses Suit.—In the suit brought by Dr. Clarence V. Grey, Elba, against the town of Darien to recover $100 for medical services rendered an alleged pauper, on September 1 the jury returned a verdict of no cause of action and judgment with costs was entered against the plaintiff.

Complies with Law.—In compliance with the provision of the law requiring physicians to register in counties in which they practice, Dr. Welcome L. Filkins, Albany, who had been charged by representatives of the Madison County Medical Society with a violation of the public health law, was discharged from custody.

Hospital Incorporated.—The Eastern Long Island Hospital Association of Suffolk County has been incorporated to maintain a hospital and dispensary. Among the directors are the following physicians: Drs. Barton T. Skinner, Clarence C. Miles and Arthur C. Loper, Greenport; Dr. Frank E. Benjamin, Shelter Island, and Dr. J. M. Hartranft, Southold.

The Work of the Mission.—The Fresh Air Mission, Buffalo, in its report of work done during the summer at Cradle Beach, showed that 698 children were received through the regular two weeks' outings and that 51 others were cared for at St. Margaret's Convalescent Cottage. The hospital at Athol Springs has been almost full since the opening day.

Personal.—Dr. George E. Beilby, resident physician at the State Industrial School, Rochester, has resigned.——Dr. and Mrs. Florence O. Donohue, Syracuse, returned from Europe August 13.——Dr. William R. Wells, Mount Morris, received the congratulations of his friends August 18 on the eighty-sixth anniversary of his birth.——Dr. Albert L. Beahan, Canandaigua, was operated on for appendicitis August 25 and is doing well.——Dr. Mary Clayton, Ogdensburg, has been appointed physician at the Binghamton State Hospital, to succeed Dr. Mary O'Malley, resigned.——Dr. Charles I. Redfield, Middletown, has been elected a member of the medical board of Thrall Hospital, vice Dr. David B. Smiley, deceased.——Mr. Alec. H. Seymour, Binghamton, has resigned the clerkship of the Broome County Surrogate's Court to accept the secretaryship of the State Board of Health, succeeding Dr. William E. Johnson, Waverly.——Dr. Henry L. Elsner and family, Syracuse, returned from a trip to Scandinavia August 30.——Dr. C. H. Glidden, Little Falls, has been appointed health officer of Little Falls.——Dr. Nathan Jacobson and family, Syracuse, returned from Europe September 2.

New York City.

Bequest for Hospital.—Among the numerous charitable institutions benefited by the will of the late Edward Whelan is St. Mary's Hospital, Brooklyn, which received $5,000.

New Hospital Busy.—The St. Gregory's Free Hospital and Ambulance Station, which was opened at 93 Gold Street on June 9, has treated more than 3,500 cases since that time and at present receives on the average 75 emergency and accident cases a day.

Typhoid Fever Decreasing.—The latest report of the health department shows a decrease of 47 cases of typhoid fever in the city in the week. The prevalence of this disease was greatest during the last week in August, but the death rate at the present is almost normal.

Harvey Society Lectures.—The first lecture of the recently organized Harvey Society will be given by Prof. Hans Meyer, who will speak in German, on "The Theory of Narcosis," October 7, at 8:30 p. m., in the New York Academy of Medicine. The second lecture will be given October 14, at the same hour and place, by Prof. Carl von Noorden of Frankfort, on "Modern Problems of Metabolism." The lecture will be delivered in English.

In Trouble.—For swindling the poor folks of the East Side, posing in the guise of a healer of the sick, Alfred Meyer, a former convict, was sentenced August 4 in the Court of Special Sessions, Manhattan, to imprisonment for eleven months in the penitentiary on Blackwell's Island and to pay a fine of $500.——David Antonio, a "voodoo" doctor, on August 31 was sentenced to imprisonment for six months for practicing medicine without a license.

Heavy Fine for Milk Dealer.—On September 8 a new justice had his first experience with offenders against the pure milk ordinances. In the first case, in which a plea of guilty was entered, a fine of $75 or thirty days in the Tombs was imposed. Ten of the other offenders pleaded guilty, preferring to have their cases postponed until some other justice presided. Those held were warned that another plea of guilty would mean imprisonment with no alternative fine.

Notes from Quarantine.—There were seventeen persons removed from the Panama steamer *Mexico*, who were sent to Hoffman's Island for observation. This is the largest number taken from a canal zone steamer in several months.——The yellow fever patient at Hoffman's Island shows signs of improvement, and it is believed that he will recover.——The Hamburg-American liner *Moltke* brought no steerage passengers, a case of cholera having appeared among the Russian immigrants at Hamburg.

Personal.—Mr. and Mrs. Arthur S. Chittenden arrived on the *La Bretagne*, from Havre, September 12.——Dr. and Mrs. Edward P. Kinnicutt arrived from Antwerp on the *Kroonland* September 12.——Dr. Vincenzo Sellaro has been threatened with death by the Black Hand if he does not surrender $5,000 to them.——Dr. Hugh C. Parmenter was removed from his position as senior surgeon at Harlem Hospital by order of Superintendent Armstrong of Bellevue and allied hospitals, on the charge of abusing the father of a patient in the hospital. Dr. Parmenter has appealed and hopes to have the case reinstated.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended September 2, 670 cases of tuberculosis, with 147 deaths; 282 cases of typhoid fever, with 21 deaths; 144 cases of diphtheria, with 13 deaths; 122 cases of measles, with 11 deaths; 48 cases of scarlet fever, with 2 deaths; 18 cases of cerebrospinal meningitis, with 8 deaths; 7 cases of varicella and 1 case of smallpox. For the week ended September 9, 396 cases of tuberculosis, with 146 deaths; 184 cases of typhoid fever, with 23 deaths; 117 cases of diphtheria, with 14 deaths; 95 cases of measles, with 7 deaths; 48 cases of scarlet fever, with 2 deaths; 12 cases of cerebrospinal meningitis, with 12 deaths; and 8 cases of varicella.

NORTH CAROLINA.

Medical College Opened.—The Department of Medicine of the University of North Carolina, Raleigh, opened for its fourth annual session September 11.

Vital Statistics.—The mortuary reports for July from 21 towns show that 290 deaths have been reported, equivalent to an annual death rate of 22.6 per 1,000. Diarrheal diseases caused 73 deaths; consumption, 33; typhoid fever, 25; heart diseases, 14, and brain diseases, 11. Of the 290 deaths 129 were of children under 5 years of age.

Personal.—Dr. Edward C. Register, Charlotte, has spent the summer in Europe.——Dr. Eugene B. Glenn, Asheville, has ben made major surgeon of the N. C. N. G., and assigned to the First Infantry.——Dr. William DeB. MacNider, Raleigh, has been elected professor of pharmacology and bacteriology in the Department of Medicine of the University of North Carolina.

NORTH DAKOTA.

Personal.—Dr. W. G. Brown, Fargo, formerly of St. Cloud, Minn., has recently returned from Europe.——Dr. S. G. White has located in Minot.

Illegal Practitioners Arrested.—Dr. J. H. Sweeney was recently arrested at Lehr, McIntosh County, and fined $50 for practicing medicine without a license.——Dr. J. Bergstrom, Cooperstown, was fined $50 for a similar offense.

Medical College Opened.—The Medical College of the University of North Dakota will open September 26. The dean announces that the university laboratories, equipment and instruction have been so arranged as to offer a combination of two years of academic work and two years of premedical work, so that the certificate of graduation from the academic department will admit students to the third year in the medical college.

OKLAHOMA.

Personal.—Dr. Leopold Kaffle, Oklahoma City, has been made assistant physician at the Insane Asylum of the State of Louisiana, Jackson.

Hospital Closed.—The Oklahoma City Hospital, Guthrie, one of the important institutions of the city, was closed July 31, owing to disagreement of the staff regarding its management, and the patients were removed to St. Anthony's Hospital.

Hospitals Incorporated.—The Mangum Hospital has been incorporated with $10,000 capital stock.——Dr. John H. Scott has opened a nineteen-room hospital at Shawnee.——The Woods County Hospital Association has been incorporated at Alva with a capital stock of $10,000.

Asylum Investigation.—The committee appointed to examine the conditions existing at the Norman Sanitarium has reported that there has been no ill-treatment, but that the number of attendants is insufficient, that the sanitary facilities should be greatly improved, and that the colored and white patients should be kept in separate wards.

Law Not Retroactive.—The attorney-general has rendered an opinion in answer to a request regarding the osteopathic practice law, whether or not those who were practicing when the law went into effect would be required to take an examination. The attorney-general gives as his opinion that those who were in practice prior to March 17, 1903, need not be examined.

State Association Chartered.—A charter was issued July 31 to the Oklahoma State Medical Association. The headquarters of the association are at Guthrie, and the following are the officers and incorporators: Dr. Richard H. Tullis, Lawton, president; Dr. Eugene O. Barker, Guthrie, secretary and treasurer, and Drs. W. E. Dickens, Enid, James M. Bonham, Hobart, and J. Henry Barnes, Jet.

PENNSYLVANIA.

Meeting of the State Medical Society.—The annual meeting of the State Medical Society will be held at Scranton, September 26, 27 and 28. The address in medicine will be given by Dr. Solomon-Solis Cohen, Philadelphia.

Typhoid at Nanticoke.—Typhoid continues prevalent in Nanticoke and new cases are still being reported. Dr. Frederick C. Johnson of the State Board of Health is investigating the cause of the epidemic and has charge of the fight against the disease. There were 27 new cases reported September 13. Altogether 212 cases have been reported.

Reading Relief Report.—The statement of the Philadelphia & Reading Railroad Relief Association for the month of July shows an expenditure of $19,907.20, of which $8,950 was paid for deaths and $10,957.20 for disability. The number of deaths was 17; 5 were accidental and 12 from natural causes. The number of new cases reported was 1,035.

School Teachers Asked to Observe Health Laws.—Apropos of the opening of public schools September 11 Dr. Samuel G. Dixon, state commissioner of health, has communicated with the principals of all the public, private and parochial schools throughout the state, calling their attention to the statute requiring all pupils to be successfully vaccinated before being admitted.

Philadelphia.

Visitors from Abroad.—Dr. Raymond Santos of Lisbon, Portugal, visited the city hospitals and medical schools last week.——Dr. Charles Keys, a resident of Brazil, is paying a visit to this city.

Medical Inspection in August.—The report of the division of medical inspection of the Bureau of Health for August shows that there were 14,486 inspections made, excluding schools; that 372 fumigations were ordered; 5 cases presented for special diagnosis; 60 cultures taken for examination; 60 injections of antitoxin given, and 892 vaccinations performed.

Health Report.—The deaths reported from all causes during the week ended September numbered 399. This is an increase of 25 over the number reported for the previous week and a decrease of 9 from the number reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 10; diphtheria, 4; tuberculosis, 65; cancer, 17; meningitis, 2; apoplexy, 12; heart disease, 34; acute respiratory disease, 23; enteritis (under 2 years), 44; enteritis (over 2 years), 5; nephritis, 27; suicide, 6; accidents, 23, and marasmus, 20. There were reported 166 cases of contagious disease, with 16 deaths, as compared with 196 cases and 17 deaths in the previous week.

RHODE ISLAND.

Receiver Appointed for Hospital.—Dr. Thomas H. McNally, mayor of Central Falls, has been appointed temporary receiver of the Pawtucket General Hospital.

For the Benefit of the Tuberculosis Camp.—The fête of Mr. and Mrs. Frederick W. Vanderbilt, Newport, August 15, netted $13,500 for the tuberculosis camp at Pine Ridge.

Medical Inspectors of Schools.—The Providence Board of Health has decided to appoint two physicians to visit private schools and see that the children in attendance are afflicted with no contagious disease. A physician is also to be detailed for duty at the office of the health board to examine such children as may be sent there from the public school.

Hospital Opened.—The two new wings of the Woonsocket Hospital, one of which was the gift of Mrs. Mabel Rathbun Jenckes, wife of Dr. Frank H. Jenckes, and the other built with funds raised by different public entertainments for the benefit of the hospital, were opened recently for public inspection. The hospital itself has been remodeled and newly equipped.

Twin City Hospital.—The first meeting of the board of directors of the Twin City Hospital was held at Pawtucket September 4, when the following were confirmed as a permanent hospital staff: Surgery—Drs. William L. Harris, Richard P. Boucher, Providence, and Raynor Woodhead, Valley Falls; Medicine—Drs. Thomas H. McNally, Central Falls, and William O'Brien; Gynecology—Drs. William H. Heimer, Pawtucket, and Joseph Myre, Central Falls; Eye, Ear, Nose and Throat—Dr. Henry M. Jewett, Providence.

GENERAL.

Smallpox in Cuba.—A fatal case of smallpox in a child has been reported from the village of Palma Soriano, in the province of Santiago.

The Association of Erie Railroad Surgeons.—This association held its annual meeting at the Hotel Astor, New York City, September 12 and 13, under the presidency of F. A. Goodwin of Susquehanna, Pa. The following officers were elected for the ensuing year: President, M. S. Cramer, Kenton, Ohio; vice-president, D. A. Currie, Englewood, N. J.; secretary and treasurer, J. A. Allis, Montclair, N. J.

Association of Military Surgeons of the United States.—The fourteenth annual meeting of this association opens in Detroit September 26. Among the distinguished foreign representatives are Dr. S. Suzuki, surgeon-general of Japan and chief surgeon of the combined fleets of Admiral Togo; Drs. Ho Kan Yen of the Chinese Navy, Ying Yung Tsui of the Chinese Army, and Wang-Hang-Chung of the South China Army, and representatives from the British, Mexican, Canadian, Guatemalan and other foreign services. The representatives of the medical department of the United States Army are Col. Valery Havard, assistant surgeon-general, who has just returned from Manchuria, and Majors William C. Borden and Charles M. Gandy. In addition, Major Louis Livingston Seaman, who has just returned from the seat of war in Manchuria, will give his experiences from the viewpoint of the Japanese Army at the front. The meetings will be held in the auditorium of the Hotel Cadillac, the first session opening at 10:30 a. m., Tuesday, September 26.

The Yellow Fever Situation.—In New Orleans the yellow fever situation continues encouraging. The new cases each day run from 25 to 40, but there are few deaths. The heroic efforts of Tallulah have promptly improved the situation, and elsewhere in Louisiana the epidemic waned. In Mississippi, Vicksburg and Natchez continue to report a few new cases, but vigorous efforts have brought the disease fully under control. Arkansas is relatively quiet. Governor Davis has appointed Dr. Ben. L. Harrison, Jonesboro, to succeed Dr. William H. Jackson on the State Board of Health. In his letter of appointment the governor said: "The State Board of Health will be recognized in the future as a human institution."——The case at Maysville, I. T., proved not to be yellow fever.——Florida has presented the most unfavorable news of the week. There has been a sharp increase of new cases in Pensacola, together with some failure of public effort to meet the conditions.——Atlanta and the state of Georgia maintain a sort of armed neutrality.——At Chattanooga the local superintendent of quarantine was discharged for permitting two refugees to drive through the town.——At Columbia, S. C., the board of health resigned because the city council would pay no attention to its recommendations.—Menominee, Mich., and Marinette, Wis., each reported a refugee ill with yellow fever.

FOREIGN.

Variola in Chili.—According to the *Public Health Reports*, the epidemic of variola is increasing and is spreading from city to city.

Mushroom Poisoning.—The German public health authorities have issued a pamphlet on "Mushrooms," which is given free to officials and organizations for distribution.

Professor Toldt of Vienna in the House of Lords.—The well-known professor of anatomy at Vienna, Karl Toldt, has been appointed a life member of the Austrian house of lords.

Graefe Medal Goes to Hering.—The German Ophthalmological Congress has awarded the Graefe medal this time to Professor Hering of Leipsic for his works on the physiology of optics.

Next French Congress of Neurologists and Alienists.—The question to be discussed at the next meeting, which will be held at Lille in 1907, are the "Senile Brain" and the "Responsibility of Hysterics."

Principles of Ethics in Spanish Dress.—The *Boletin de la Asociacion Medica de Puerto-Rico* has just concluded the publication, in Spanish, of the Principles of Ethics of the American Medical Association.

Mailing of Infectious Material.—The German government now requires that infectious material from or forwarded to bacteriologic institutes must be mailed in special receptacles, made according to government models.

New Hospital in French Indo-China.—The authorities at Cambodia, in French Indo-China, it is reported, have decided to establish a general and lying-in hospital for natives at Phom-Penh. The work of construction is to be started immediately.

First International Congress for Psychiatry and Neurology.—It is announced that the First International Congress of Psychiatry and Neurology is being organized to convene at Amsterdam, Sept. 3-8, 1907. Professor Jelgersma of Leyden will preside.

Medal for Work on Vaccine.—The French Académie de Médecine, through the minister of the interior, has awarded a silver medal to Dr. Alan Green, bacteriologist in charge of the vaccine lymph department of the Lister Institute of Preventive Medicine, for his work on vaccine, published in the Proceedings of the Royal Society.

Plague in the Argentine Republic.—It is reported that there has been a reappearance of this disease in Santiago del Estero. The sanitary authorities are taking every possible precaution to prevent the spread of the disease, and are especially directing their efforts toward extermination of rats in private dwellings as well as in public buildings.

Epidemic Cerebrospinal Meningitis in Germany.—The epidemic seems to be declining in Silesia, where it made its first appearance with such ravages. It is becoming more prevalent in Western Prussia, and some leading medical authorities, we learn, are quite pessimistic in regard to it, even asserting that the disease may prove to be the terror of the twentieth century and sweep over the world.

Anti-tuberculosis Campaign in Bulgaria.—The Association of Bulgarian Physicians has had a popularly written "Catechism for the Fight Against Tuberculosis" printed and distributed gratuitously throughout the country, especially in educational centers. All the schools of the upper grades now have each a medical inspector who lectures occasionally on hygiene and inspects the scholars twice a week to detect transmissible diseases.

Death of Physician from Hydrophobia.—Dr. Feiber of Holzapfel, Germany, was bitten by a mad dog three months ago. The wound was carefully treated and he went the next day to the Berlin Institute for Infectious Diseases, where he was given twenty-one preventive inoculations and was then dismissed as cured. He did not believe that the cure was complete, and ten weeks after the injury symptoms of hydrophobia developed, fatal in four days.

The Neuburger Endowment for Scientific Research.—The friends of Dr. T. Neuburger of Frankfort, Germany, presented him with $20.000 on the occasion of his fiftieth professional anniversary, two years ago. He added $5.000 and presented the sum to the authorities to be applied to promote scientific researches. It has been decided to devote the income from the endowment for the next five years to the cancer research work at the local Institute for Experimental Therapy.

Training in Forensic Medicine.—Two years ago the Paris medical faculty organized an Institute of Legal Medicine and Psychiatry to aid in training medicolegal experts for the courts. A diploma in legal medicine and psychiatry was given on completion of the course, which was open to any physician or university medical student, native or foreign. The *Semaine Médicale* brings the information that the course has been recently enlarged to include criminology and penal law, mental and legal medicine.

Cholera in Madras.—The epidemic in Madras is said to have assumed alarming proportions. The death rate for the last week in July was 89 per 1,000, and in some places is said to have reached 200 per 1,000. The infection is said to have been carried to villages in the suburbs of Madras, and unless severe measures are quickly adopted it is feared that the epidemic will spread to the railroad work shops at Perambore, where are thousands of workmen, and even to the Madras water supply at Red Hills.

Rejection of Recruits with Tendency to Mental Affections.—The German authorities have recently issued more stringent regulations to prevent the acceptance of new recruits with a tendency to mental affections, and to detect those already enrolled. In a number of garrisons permanent arrangements for postgraduate training in neurology and psychiatry are to be made. For several decades a course in psychiatry has been obligatory for the students in the military medical college at Berlin. The official notice also contains suggestions for detection of simulation.

Prizes Offered by Mexican Academy of Medicine. — Two prizes of $500 each are offered for the current year by the National Academy of Medicine at Mexico. The first is for the best work on the early diagnosis of tuberculosis and means to prevent its spread. The second prize is for the study of leprosy in Mexico, its most frequent clinical types, and means to prevent its spread. Competing articles must be received by the secretary before October, 1896, accompanied by the name of the author in a sealed envelope. The only condition is that the articles must be in Spanish.

The Leipsic Chair of History of Medicine.—The chair provided by the Puschmann endowment has been fully organized, and Prof. Karl Sudhoff of Hochdahl has accepted its incumbency. He has recently been made chairman of the permanent international committee of arrangements for the International Historical Congress of investigators interested in the study of the natural sciences. Sudhoff's name is well known by his researches on the works of Paracelsus. The Puschmann endowment provides also for other features of the history of medicine besides the professorship, as already mentioned in these columns.

Postgraduate Schools at Milan.—It is reported that by arrangement between the Italian ministers of public instruction and finance, the official representatives of the province and commune of Milan and the managers of the hospitals of that city, it has been decided to establish postgraduate schools of clinical midwifery and gynecology, diseases of occupation, and contagious epidemic diseases. The first will have 200 beds, the second 60, and the third 164, distributed among seven pavilions. Others may be created later. The estimated cost of these establishments is $53,000. The directors are to rank with university professors.

Epidemic of Anterior Poliomyelitis in Norway.—Platou describes in the *Tidsskrift f. d. Norske Laegefor.* for September an epidemic of 20 cases of acute anterior poliomyelitis in his district last year, with 6 deaths. The first cases seemed to develop from contact infection, but no connection could be determined for the later scattered cases. The age of the children ranged from 7 weeks to 14 years. No adult was attacked. The legs were affected with paralysis more than the arms; complete hemiplegia was not observed in any instance. The severity of the disease varied in different cases, some running an abortive course, while death occurred abruptly in others. The disease terminated fatally or else in complete recovery in time. Treatment and disinfection were the usual measures.

Return to Germany of Professor Baelz of Tokio.—Professor Baelz has returned to his old home, Stuttgart, after a residence of twenty-nine years in Japan. For twenty-five years he has been a leading and pioneer professor in the medical college at Tokio, and almost all the Japanese physicians of the day have been his pupils. His works on the anthropologic and pathologic peculiarities of the Japanese have been numerous and important, as also his contributions to the study of beriberi and other tropical diseases. He is now 60 years old, and received many tokens of friendship and esteem from the mikado and empress of Japan and Japanese scientific societies, as well as from personal friends, before he left the country last June. He was professor of physiology at first and later of internal medicine and gynecology. He married a Japanese.

Laryngologists Refuse to Take Part in Approaching International Medical Congress.—The laryngologists of the world have taken exceptions to the rulings of the Fifteenth International Medical Congress, which group otology, rhinolaryngology and stomatology in a single section. The laryngologists of Great Britain have officially declared that they would refrain from participating in the congress and the Germans are following suit. The committee of arrangements of the international congress have consequently notified the national committees of propaganda that the rulings have been modified so that Section XII is now divided into three subsections, Rhino-laryngology, XII a, Otology, XII b, and Stomatology, XII c. The laryngologists have long been considering the advisability of holding a specialist international congress, and occurrences seem to be tending this way.

Pecuniary Damages for Inoculation with Syphilis.—A Berlin court recently awarded a young woman $725 and a monthly allowance of $37, as she presented testimony to show that her health had been seriously undermined by syphilis transmitted by a druggist with whom she cohabited. These sums were reduced to $400 and a monthly allowance of $12.50 by the court of appeals. The defendant based his defense on the fact that the woman was not an ignorant young girl, and that three physicians who had been treating him for syphilis contracted two years before, had declared that he was entirely cured a month or so before the relations with the young woman had commenced. The judge remarked that the defendant must have been fully aware of the malignancy of the disease, and must have known that he might transmit it after two years, as it is liable to remain virulent for three years or more.

First International Congress of Physicotherapy.—The membership of this congress, which met at Liège August 12, numbered over 650, and fully 200 members took part in the discussions. The principal countries were officially represented and great enthusiasm prevailed among the members. Jacques of Brussels remarked that in this congress physicotherapy left the domain of empiricism and acquired a soul. The empirics were represented in the congress, and the measure proposing to limit the practice of physicotherapy to physicians was modified so that it was not so drastic as its promoters intended. The congress was divided into four sections, hydrotherapy and climatotherapy, electrotherapy, radiology and treatment by movements or exercise. It was voted to organize another similar congress two years hence, and Geneva was chosen for the meeting place. Dr. F. B. Bishop of Washington was the official delegate from this country.

League of Defense Against Anemia.—Twenty-five prominent citizens of Porto Rico gathered at San Juan, August 6, and organized the national "Liga de Defensa contra la Anemia." Seventeen of those present were physicians; the honorary presidency of the league was conferred on Dr. B. K. Ashford, with J. G. Martinez as acting president. Ashford advocated dividing the island into five to ten districts with a hospital of forty beds in a central station in each district and traveling dispensaries, going from village to village until treatment, advice and the principles of sanitary living are imparted to every corner of the island and every inhabitant. The league intends to solicit the further aid of the government and collect subscriptions for the work, and have every physician enrolled in its membership. Weekly lectures are to be given, explaining to the people the necessity and means of preventing uncinariasis. The league also plans to publish circulars and distribute annual prizes to those who distinguish themselves in propaganda and investigation.

Confusion in Smallpox Statistics in Germany.—Official declaration of cases of smallpox is compulsory for physicians in Germany, but as so very few of them have ever had a chance to see a case of the disease, it is frequently difficult for them to recognize it. This fact renders more astonishing a recent statement in the Paris *Progrès Médical*, with comment in other French exchanges, to the effect that during the last few months 2.726 cases of smallpox have occurred in Prussia, with 1.534 deaths. The figures are those of the epidemic of cerebrospinal meningitis, and our French exchanges evidently did not recognize the familiar disease under its German name of *Genickstarre*. This term means stiffness of the neck, and is another instance of the habit which scientists so often have occasion to deplore—the use by the Germans of colloquial terms in the titles of scientific writings, which foreigners are unable to recognize without a dictionary. The term cerebrospinal meningitis is common to all languages nowadays and it is freely used in Germany, but the popular term *Genickstarre* is still often used, and to the confusion of French editors in this case.

Monument to Semmelweis.—A committee has been formed at Budapest to collect subscriptions for a monument to I. P. Semmelweis, in honor of his work on the etiology of puerperal fever. He was born in that city in 1818, and was resident physician at the Vienna Maternity when he noted the resemblance between fatal pyemia from a scratch at the dissecting table and fatal puerperal fever. He ordered all the students to wash their hands in a solution of calcium chlorid before examining a lying-in patient, and with this order reduced at one stroke the number of cases of puerperal fever to the minimum. Dr. Oliver Wendell Holmes in this country had announced, a short time before, that puerperal fever was infectious. This was probably unknown to Semmelweis. His discovery was not announced and did not become generally known until several years after, when it was published abroad by a general practitioner and a dermatologist of Vienna. Semmelweis' first article on the subject appeared not long after in Hungarian, but the world knew little of it until 1860, when he published a large work in German on the etiology and prevention of puerperal fever. He died in an insane asylum at Vienna in 1865. Two biographies of him have recently been published, one in English and one in German. The latter, although incorrect in some points, gives a good picture of the man and his life work.

Dangers of Medical Certificates.—A certain Belgian physician has been the defendant in a suit for damages which has been dragging through the courts for four years, until recently dismissed. The plaintiff did not have the slightest grounds for his suit, but he was able to keep it in the courts and barely missed gaining his point. He was enabled to do this by certificates furnished him by thoughtless physicians, testifying that he was the victim of a nervous affection "apparently due to an operation on the testicle in 1898, performed by some empiric," or "the result of a badly treated testicular affection." A third certificate stated that the nervous affection was the "result of an operation on the testicle in 1898." These certificates had been given him by thoughtless hospital physicians, who commiserated his condition and accepted without investigation his statements that the operation on the testicle had been the source of his ills. The plaintiff, who had performed the operation, was an interne at the time, and the operation was skillfully done. The patient then had already been under treatment for the nervous affection which he attributed later to the operation. He could not have obtained a hearing in the courts if it had not been for the certificates he produced from three medical authorities who allowed their philanthropic emotions to blind them to the necessity for cautious investigation of the case. In delivering such a certificate, the *Gazette méd. Belge* comments, the possible injury to a third party should always be borne in mind, and the applicant's statements should not be accepted without investigation.

Cholera in Europe.—Our Russian exchanges under the heading of "Epidemics," mention the yellow-fever situation at New Orleans and the plague in India, but have nothing to say in regard to any epidemic diseases in Russia except that 14 cases of epidemic cerebrospinal meningitis were reported throughout the entire empire during July. Our German exchanges state that the cholera-infected region in northeastern Prussia is enlarging, and that new cases have been found on some of the other waterways besides those first infested. So far, the disease has been confined to raftsmen coming through from Russia and persons in contact with them. Up to August 30, 20 cases suspicious of cholera had been reported to the authorities, and bacteriologic examination showed that 12 were true cholera, with 6 deaths. A third case has been discovered at Hamburg. The epidemic in Germany has reached a total of 202 cases, with 77 deaths, according to cable reports dated September 18. The record for the twenty-four hours preceding was 3 new cases and 1 death. Sixteen districts have been declared infected and precautionary measures taken. The *British Medical Journal*, editorially, states that the responsibility which rests on Germany at the present is very great. Practical sanitation in the remote, small towns is still in a very backward state, and the conditions across the border in Russia are still worse. The British and American authorities are on the alert defensive, and are enforcing the measures which proved successful in warding off cholera during the previous epidemics in Europe.

Revolution in Nursing in France.—The Journal has mentioned several times the expressions of wonder and admiration lavished by French medical visitors on the trained nurses of America and England. Nothing like the trained nurses of these favored lands has hitherto been known in France. The hospitals offer no accommodations suitable for gentlewomen, and the profession of nurse has therefore never appealed to this class of women seeking a means of self-support. For centuries the nursing was done by sisters of charity, and only comparatively recently have the hospitals been laicized. A beginning has now been made that promises a revolution in nursing methods, and the *Journal de Méd. de Paris* proudly asserts that it is no longer necessary for the French physician to expatriate himself to behold a model training school for nurses. The physician, Dr. Lande, who is mayor of Bordeaux, has succeeded in organizing in the new city hospital, the Tondu, a training school for nurses on the latest and most approved lines. Its success has been marvellous, the editorial adds, during the year since it was organized; "the patients themselves seem transformed. One can read in their eyes their delight in being surrounded by kind, devoted and sympathetic young women in an atmosphere of physical and moral cleanliness." The *American Journal of Nursing* states that this revolution is due in great part to Dr. Anna Hamilton, who ten years ago took charge of the nursing and founded a training school for nurses at the Protestant Hospital at Bordeaux. Her graduates are now ready to carry the reform to other hospitals. In Paris another group of women has established a small model training school for nurses in the heart of Paris, connected with two private hospitals. It is a striking object lesson for the authorities in charge of the public hospital work, and will no doubt aid effectually in the revolution now going on in hospital nursing in France.

Campaign Against Yellow Fever in Mexico.—Isolated cases of yellow fever still occur in Mexico and will probably continue to occur here and there, but the prompt, systematic and radical measures taken stamp out the disease before it has a chance to develop into an epidemic. In his official report for 1904 Liceaga, chief of the National Board of Public Health, states that during 1903 and 1904 there were 699 cases throughout the entire republic, and 147 deaths. From September, 1903, to January, 1905, house-to-house visits were made to the number of 1,081,177, and 751 immune persons and 99,372 non-immune were taken in charge. The number of inspections of deposits of water was 126,081, and inspections of immune persons, 455,801; of non-immune, 678,009; of travelers arriving, 10,073, and of travelers leaving, 12,314. Nearly 4,500 dwellings, 67 ships and 1,813 railroad cars were disinfected; 237,521 collections of water were drained away or treated with kerosene. Disinfection of the loosely-built native huts is a difficult matter. He found that the mosquitoes were able to escape by the smallest outlets. In one of his tests ten mosquitoes were placed in a small air-tight room which was then fumigated. A cover had been placed over the keyhole outside. Seven of the mosquitoes were found dead in the room, but the three others were found in the cover over the keyhole. In one experience in a fortress, where the windows formed long passages through the thick stone walls, the mosquitoes sought refuge in the depths of these windows, and the air in them prevented the entrance of the sulphur fumes. When the windows were opened the mosquitoes escaped alive. As soon as sulphur was set to burn in each separate window passage the epidemic of yellow fever ceased at once. He closes the native huts mosquito-tight with a cloth covering outside. A strip of canvas is carried from the foot of the wall to the eaves and here supported by a bar of wood on uprights. It is then carried over the roof and down the other side to the foot of the wall. Other strips are applied in the same way, lapping over the first, until the sides and roof of the hut are covered. The front and rear are then covered with strips sewed together to make a solid sheet, sewed also to the first of the strips passing over the sides and roof. This insures the killing during the sulphur fumigation not only of the mosquitoes, but also of all the other insects that had found shelter in the structure. Liceaga adds that the general mortality of Vera Cruz has been much reduced by the sanitary and prophylactic measures undertaken there in the campaign against yellow fever. It was only 1,858 in 1904; in 1903 it was 2,566. The deaths from yellow fever were reduced from 375 in 1903 to 12 in 1904, and four of the latter were imported cases.

Pharmacology

Scientific Work Misrepresented and Commercialized.

In pursuance of the deliberately assumed purpose to enlighten the physicians of the United States on all features of the traffic in proprietary remedies, there will be offered to our readers not only information regarding the composition of such remedies, but also facts concerning the methods of their advertising and sale, which come to light in such shape as to be of service to the profession. No firm or product will be subjected to attack, but publicity will be given to all facts obtainable. Having in mind this purpose the following recital of facts is offered to the profession as an illustration of methods employed in the proprietary trade, and as a step in the era of pharmaceutic publicity.

Under date of Dec. 1, 1904, there was published by the government of Porto Rico a "Report of the Commission for the Study and Treatment of 'Anemia' in Porto Rico." The splendid scientific results of this study of uncinariasis we commented on editorially[1] February 11, page 478. A few weeks ago the M. J. Breitenbach Company of New York circulated among physicians what purports to be an abstract of this report, claiming that "this report alone would suffice to establish pepto-mangan at once as the foremost hematinic known." Physicians, of course, realize that no other proprietary firm ever had so many "original" "write-ups" inserted in the reading pages of medical journals. It may fairly be said that the medical press has been subsidized by the Breitenbach Company to an extent equaled by no other. So in this instance, medical journals have recently been publishing as "reading notices," or as "publishers' notes," extracts from the company's pamphlet, especially made for the purpose. The Breitenbach Company having, as quoted, staked so much on the results of the commission's use of "pepto-mangan (Gude)," it becomes a matter of medical importance to look into the facts.

The commission treated, so far as covered in this report, 5,490 cases of uncinariasis. Of these it presented in detail the clinical histories of 61 cases. In 18 of these 61 cases the commission administered "pepto-mangan (Gude)," which had been donated by the Breitenbach Company. Of these 18 cases the Breitenbach Company says they "were selected on account of their extreme severity, and thus these cases represent the most crucial test to which any iron preparation can be subjected." Further, we are told: "The results obtained point so distinctly to the supremacy of "pepto-mangan (Gude),'' etc., and "the report may be regarded as a supreme test" and "as a triumph for pepto-mangan (Gude)."

With these claims before us it is more than interesting to analyze the reports of the cases from which they are drawn. In 14 of the 18 "pepto-mangan (Gude)" cases that combination was the only iron preparation used; in the remaining 4 Blaud's pill was used during the latter part of treatment. In the other 43 cases (not mentioned in the Breitenbach pamphlet) the iron was administered in the form of Vallet's mass or Blaud's pill, either or both, with the exception of two cases in which no iron was used. In closing its report the commission notes that iron alone without expulsion of the uncinaria is of little benefit and plays a part secondary to anthelmintics. Therefore, in this "supreme test," the relative value of the hematinic used will be largely determined by the time consumed in relieving the symptomatic anemia after removal of the parasitic cause.

---

[1] This editorial brought from the Breitenbach Company a letter addressed to THE JOURNAL of the American Medical Association, which is worth quoting in this connection, and also in connection with the correspondence with the *Medical Record*, which follows. The italics are ours.

"It seems to us, in looking over the issue of your journal for Feb. 11, that the editorial department of your publication is quite *at variance with your advertising pages.* A short while ago we sent you a new electrotype stating that peptomangan was particularly applicable to the anemia of uncinariasis, and produced positive results if administered after proper treatment for the expulsion of the parasite. We did not make this statement until we had had conclusive proof from tests made by eminent men in the profession that such was the case. We make no haphazard statements ourselves. *It is evident that either your editors do not read the advertising pages of your journal, or they wish to make a direct slap at one of their advertisers, and we can hardly see how it is to be any advantage for us to place an advertisement with you, if in the editorial pages you are going to directly contradict our statement.* We refer to your editorial on page 478, in which you make the statement. 'The day of blind *reliance on iron, quinin and tonics in general in the treatment of anemic conditions in tropical countries is past, never to return,'* and this in the face of our advertisement for which we pay you. It looks to us a little like taking our money and in turn going out of your way to slap us in the face, for had that paragraph been omitted from your editorial, we think you will agree with us that the value of the article would in no way have been lessened, and we should feel in a very different frame of mind than we do now. Had it been written by one of your contributors we would have let the statement pass, and set it down to ignorance, but coming as it does from your editors, *who should be thoroughly conversant with the advertisements you carry,* we can not but feel that it is *very unfriendly* toward us.

"We shall be glad to hear from you on the subject."

Analyzing the 61 cases the following facts come to light, and it should here be noted that nothing in the original report indicates the "extreme severity" of the "pepto-mangan (Gude)" cases as compared with those in which other iron preparations were used. For the present purpose it is sufficient to compare the "pepto-mangan (Gude)" cases with those in which Blaud's pill alone was used:

	Cases.	Av. time of treatment. Days.
"Pepto-mangan (Gude)" cases reported cured	9	79.77
"Pepto-mangan (Gude)" cases reported cured in which Blaud's pill was used in latter part of treatment	5	74.8
Blaud's pill cases reported cured.	26	49

Two "pepto-mangan (Gude)" cases were reported "improved" in an average treatment time of 87 days, while the other two were fatal cases. This "supreme test" then shows that the patients treated with Blaud's pill recovered from the anemia in less than two-thirds of the time required when "pepto-mangan (Gude)" was used. On this point the commission itself says (page 119): "Thus it is quite difficult to accurately judge the comparative value of different iron preparations, yet it is noticed, even by some patients, that Blaud's pill gave more rapid results."

In the face of these clinical facts and of this plain declaration from the commission, the physician may well ask: Why in the name of prudence did the Breitenbach Company circulate a pamphlet and advertise in medical journals a claim that "this report alone would suffice to establish pepto-mangan at once as the foremost hematinic known?" As the report actually draws a contrary lesson, the course of the company can only be explained either as due to its exaggerated confidence in the credulity of physicians or to its own neglect to read the report before abstracting it. Which hypothesis is most probable? Physicians who have read the "write ups" of "pepto-mangan (Gude)" appearing in nearly all the medical journals of the country will have no difficulty in answering this question. Lastly, what of the honesty of circulating among medical men so misleading a document?

The Medical Record and the Propaganda Against Nostrums.

A little while ago the New York *Medical Record* contained a two-page advertisement of the Etna Chemical Company, which evidently was intended to counteract the effect of the report of the Council on Pharmacy and Chemistry which showed phenalgin to be a simple acetanilid mixture. Still more recently the same journal contained another two-page advertisement, one of which was occupied with a cartoon intended to cast ridicule on the efforts being made against the nostrum evil. Since these advertisements appeared in a scientific medical journal and a journal that is supposed to represent intelligent physicians, one might charitab'y suppose that they were admitted through lack of supervision. Such does not appear to be the case, however.

Under date of September 8, the editor of THE JOURNAL of the American Medical Association sent the following letter to the *Medical Record:*

To the Editor:—

Your issue for last week, September 2, contains a two-page advertisement of the Etna Chemical Company relating to their preparation, phenalgin. One page is entirely taken up with a cartoon evidently intended to deride THE JOURNAL of the American Medical Association, the Council on Pharmacy and Chemistry of the American Medical Association, and the propaganda against nostrums. The other page contains what is presumed to be an answer to the official announcement of the Committee on Chemistry regarding its investigation into certain preparations offered to the profession and to the public, especially as it is related to phenalgin. Permit me to quote from the advertisement as it appears on advertising page 21 of the *Record:*

> "Recently certain ill-advised persons have attempted to confuse Phenalgin with patent and quack Nostrums and have so far succeeded that the influence of the Journal of the American Medical Association has been brought to bear against our legitimate and ethical business."
>
> "We believe that Commercialism of the rankest kind has dominated this absurd crusade against us. These people may call Phenalgin a mixture, or a compound, or anything that pleases them; it does not in the least change the fact that Phenalgin is just what we have always said it to be."
>
> "We know that doctors who are practicing medicine and prescribing Phenalgin will continue to do so regardless of the reports of alleged analytical chemists whose experience in the sick room is an atom of a myth compared with that of those who are continually using our product."

My object in writing you is to briefly state certain facts solely for the information of your readers.

What the Council on Pharmacy and Chemistry of the American Medical Association is and what its functions are are well known to your readers. While the council has been outlining plans for work, making investigation into various products, it has published but one official report: this was on six preparations, viz.: ammonol, antikamnia, Koehler's headache powders, orangeine, phenalgin and salacetin (sal-codeia-Bell). The report on phenalgin was as follows:

> "According to the analyses of the contents of the original sealed packages as purchased, this was found to be a mixture, and to contain the following ingredients approximately in the proportions given:
>
> | Acetanilid. | Sodium bicarb. | Ammonium carb. |
> |---|---|---|
> | 57 | 29 | 10 |
>
> "Certain packages of phenalgin were purchased which on analysis did not show ammonium carbonate."

The committee signing the report[1] and vouching for its truthfulness consisted of:

J. H. Long, M.S., Sc.D., professor of chemistry in the Northwestern University Medical School and director of its chemical laboratories, the author of "A Text-book of Physiological Chemistry" and other works on chemistry, and, last year, president of the American Chemical Society;

W. A. Puckner, Ph. G., professor of chemistry in the School of Pharmacy of the University of Illinois, and a contributor of scientific articles to chemical journals;

S. P. Sadtler, Ph.D., professor of chemistry in the Philadelphia College of Pharmacy, author of "A Text-book on Chemistry," associate editor of the U. S. Dispensatory, and a member of the Committee on Revision of the U. S. Pharmacopeia;

Julius Stieglitz, Ph.D., professor of chemistry in the University of Chicago, a man of wide repute as a chemist, and the author of several works on chemistry; and

H. W. Wiley, M.D., Ph.D., chief of the Bureau of Chemistry of the Department of Agriculture, Washington, D. C.

Besides the above, other chemists assisted in the work, and the following made analyses of phenalgin:

H. M. Gordin, Ph. D. (Berne), professor of chemistry in the School of Pharmacy of the Northwestern University, who has done a large amount of original work, as his contributions to chemical literature will show; and

---

[1] The Journal A. M. A., June 3, 1905, p. 1791.

Max D. Slimmer, B.S.M.A. (University of Chicago), Ph. D. (Berlin), who has several fellowships in chemistry in the University of Chicago, who has done considerable original work in chemistry, and who is recognized as an honorable and capable analytical and consulting chemist.

These are the gentlemen referred to in the advertisement in the *Medical Record* as "alleged analytical chemists."

In a former advertisement the Etna Chemical Company says: "We protest against the Association of Phenalgin in that publication" (meaning The Journal of the American Medical Association) "with patent medicines and nostrums as an uncalled-for insult to a reputable American Manufacturing Chemical Industry."

In this statement, the Etna Chemical Company gives physicians the right to ask whether it is "reputable" to inveigle them into prescribing a simple acetanilid mixture under the supposition that it is a definite synthetic chemical substance and to charge a dollar an ounce for a preparation the ingredients of which cost less than five cents.

There is, however, one assertion made in the advertisement which, I think, is well taken. The preparation is certainly not now a "secret remedy," for the Council on Pharmacy and Chemistry has cleared up all doubts as to the composition of "ammoniated-phenylacetamide."

Since you did not see fit to publish, or mention, the report referred to above, but have allowed your advertising pages to be used to slur the Council on Pharmacy and Chemistry of the American Medical Association, as well as The Journal of the American Medical Association, I think it only fair to your readers that they be informed of the facts in the case, as far as they refer to phenalgin. I, therefore, ask that you kindly publish this.

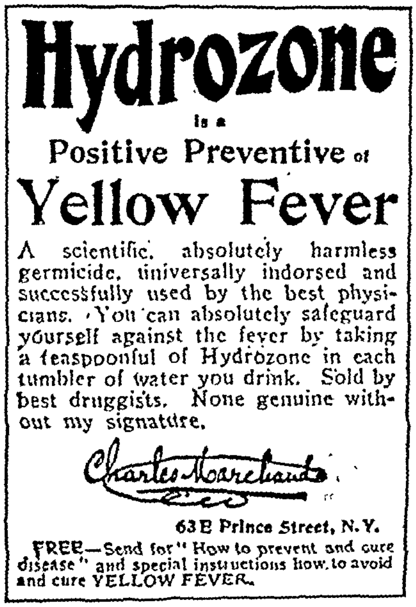
To the above the editor of the *Medical Record* replied under date of September 12:

> It has always been the aim of the editor of the *Medical Record* to keep the editorial and advertising pages of the journal entirely distinct, and in continuing that policy I am forced regretfully to return your letter replying to an advertisement in the issue of September 2. If there should at any time be anything in the reading pages of the *Medical Record* relating to you or the Association whose interests you guard so well, to which you might take exception, I promise you the opportunity to reply fully and freely; but I am not responsible for what appears in the advertising pages, and can not open the correspondence department to letters in commendation or condemnation of anything appearing in that part of the journal. I regret the seeming discourtesy to you, but you surely can see to what abuses it might lead were correspondents permitted to discuss in the reading pages the statements made by advertisers.
>
> Thomas L. Stedman.
>
> P. S.—If you publish this letter in your own journal or elsewhere, I trust you will, in justice to the *Medical Record* and to me, publish also this letter giving my reason for refusing you the hospitality of our columns. T. L. S.

We are very glad to know that "the editorial and advertising pages of" the *Medical Record* are "entirely distinct." Since antikamnia, ammonal, phenalgin and salacetin, in the form of sal-codeia-Bell, each occupies from a half to a page in the *Record*, some physicians were unkind enough to insinuate that this was the reason the editor totally ignored the report which exposed these preparations. Dr. Stedman's letter shows that this could not be, since the editorial and advertising departments are "entirely distinct."

Preying on the Sick.

The moral principle governing the action of secret proprietary and patent medicine men is an unknown quantity; sometimes it would seem to be a negative one. Just how much lower in the scale of humanity a man can go than to prey on the fears of a people in the time of a terrible epidemic for the sake of a few dollars we do not know. There may be something more despicable, but what is it? Two weeks ago we referred to the cold-blooded methods of the peruna people; this week we reproduce an advertisement from the New Orleans *States* that tells another story of man's inhumanity to man.



Hydrozone

is a

Positive Preventive of

Yellow Fever

A scientific, absolutely harmless germicide, universally indorsed and successfully used by the best physicians. You can absolutely safeguard yourself against the fever by taking a teaspoonful of Hydrozone in each tumbler of water you drink. Sold by best druggists. None genuine without my signature.

Charles Marchand

63 E Prince Street, N.Y.

FREE—Send for "How to prevent and cure disease" and special instuctions how to avoid and cure YELLOW FEVER.

This brings up the problem that we are trying to solve, viz.: "What is the difference between a 'secret proprietary medicine' advertised in medical journals to physicians, and a 'patent medicine' advertised in newspapers to the public." Hydrozone is being advertised in nearly all medical journals, and at the same time in the newspapers. Where shall we place it? And if hydrozone, with the methods recently adopted to exploit it, is tolerated in the medical press, why not peruna?

Tongaline and Yellow Fever.

Tongaline, too, is good for yellow fever if we are to believe the absurd claims made by its enterprising salesmen. Here is the advertisement from current medical journals:

> "*Stegomyia fasciata* has produced an epidemic of yellow fever in certain sections of Louisiana and adjoining states.
>
> "*Stegomyia punctata* has inoculated thousands with virulent malarial germs throughout the balance of the Mississippi Valley.
>
> "Tongaline, Mellier, in one of its forms as indicated, antagonizes and destroys the effects of these parasites on account of its extraordinary eliminative action on the liver, the bowels, the kidneys and the pores, whereby the poison is promptly and thoroughly expelled. For full literature, etc."

Correspondence

Patent Medicines: A Good Suggestion.

Rogersville, Tenn., Sept. 13, 1905.

To the Editor:—Under separate cover I am to-day mailing you a marked copy of the *Rogersville Review*, a weekly newspaper published in this, a town of about 3,000 inhabitants. I have had the editor copy your editorial[1] of September 2 on

---

1. "A Miserable Outrage," The Journal, Sept. 2, 1905, p. 722.

the patent medicine fraud as it prevails in the United States with special reference to peruna. These little weekly papers circulate among the rural people, where every issue is read through, ads and all alike. I would suggest that you induce every member of the American Medical Association to have this or some like article occasionally brought out in his home paper. Surely all the physicians of a town would have sufficient influence with their local paper to do this. I assure you that it would work wonders. The people at large have never heard anything but praise of these nostrums, and they fully believe that the ads are written and sanctioned by the medical profession.

This plan would doubtless not work in the larger cities where the advertising bills are large, but it could very easily be done with the small daily and weekly papers, published in villages and towns, as you will see. I propose to have some articles of the kind appear every week. The sums paid these small papers for carrying patent medicine ads is a mere pittance.

J. E. Miller, M.D.

Marriages

Francis J. Peter, M.D., to Miss Laura Jordan, both of Omaha, August 16.

Harry E. Alderson, M.D., to Miss Cordelia Bishop, both of San Francisco, September 26.

Arnold Brandt, M.D., Seattle, Wash., to Miss Ethel Tope of St. Louis, Mo., September 6.

William W. Jarrell, M.D., Thomasville, Ga., to Miss Sadie Luff of Nashville, Tenn., September 6.

Frank Edmoundson-Nabers, M.D., to Miss Bevelle Comer, both of Birmingham, Ala., September 6.

George Lone Everall, M.D., Clinton, Iowa, to Miss Amy Mabel Ford, at Evanston, Ill., September 12.

William Watson McKibben, M.D., to Miss Olive Beatrice Flint, both of Worcester, Mass., September 11.

Thomas Francis Coneen, M.D., to Miss Jane Cecilia Cunningham, both of Portland, Maine, September 4.

George Thomas Rankin, M.D., Akron, Ohio, to Miss Anna Allison Jones of Zanesville, Ohio, September 12.

Edwin Heddon Shepard, M.D., Syracuse, N. Y., to Miss Edna Mitchell of Hornellsville, N. Y., September 7.

James Matthew Booher, M.D., to Miss Retta Kelly Brown, both of Louisville, Ky., at Jeffersonville, Ind., April 9.

James T. Jelks, M.D., Hot Springs, Ark., to Miss Belle McKaskle, Pony, Mont., at Butte, Mont., September 7.

John H. Gilpin, M.D., Fort Wayne, Ind., to Mrs. Fred Lochrane of Montgomery, Ga., at Cincinnati, September 16.

Charles R. Chapman, M.D., Springfield, Mass., to Miss Hazel Vivian Sheffield of Chicago, at Winona Lake, Ind., September 6.

Deaths

John G. Park, M.D. Harvard University Medical School, Boston, 1866, member of the Massachusetts Medical Society; acting assistant surgeon in the Navy during the Civil War; superintendent of the Worcester City Hospital in 1871; from 1872 to 1877 assistant superintendent of the State Insane Hospital; from 1877 to 1879 on the staff of the Hospital for the Chronic Insane, and from 1879 to 1890 superintendent of the Worcester Insane Hospital, and thereafter a citizen of Groton, Mass., died in the Worcester City Hospital after an operation for gallstones, August 29, aged 67.

Thomas Menees, M.D. Transylvania University Medical Department, Lexington, Ky., 1846, one of the most eminent physicians of the South; a member of the Confederate congress and for many years a professor of obstetrics in the medical department of the University of Nashville and of Vanderbilt University, died at his home near Nashville, September 7, aged 82.

James W. Jackson, M.D. University of Louisville Medical Department, 1873, formerly of Cocoanut Grove, Fla., but recently a resident of Sherman, Texas, died in the North Texas Hospital for the Insane, August 23, from injuries alleged to have been inflicted by attendants in the asylum, who were arrested on the charge of murder.

James M. Gist, M.D. Medical Department of the University of Nashville (Tenn.), 1860, surgeon in General McRae's brigade, C. S. A., during the Civil War, twice a member of the state legislature and very prominent in White County, Ark., died at his home in Beebe, September 10, after a short illness, aged 71.

Colin P. Dewar, M.D. McGill University Medical Department, Montreal, 1882, a member of the Canadian Medical Association and past president of the Ottawa Medico-Chirurgical Society and of the Ottawa Medical Society, died at his home in Ottawa, Ont., September 7, from uremia, after an illness of five days, aged 40.

Hiram H. Russell, M.D. Starling Medical College, Columbus, Ohio, 1863, assistant surgeon of the One Hundred and First Ohio Volunteer Infantry during the Civil War, and later of the One Hundred and Thirty-eighth Infantry, O. N. G., died at his home in Hyde Park, St. Joseph, Mo., September 10, after a lingering illness, aged 70.

Lyman Potter, M.D. Starling Medical College, Columbus, Ohio, 1850 one of the oldest and most respected practitioners of Delaware County, Ohio, for many years a member of the Delaware County Medical Society, died from senile debility at his home in Leonardsburg August 29, after a decline of three months, aged 93.

Benjamin T. Kneeland, M.D. Geneva (N. Y.) Medical College, 1851, formerly of Dalton, N. Y., surgeon of the One Hundred and Thirtieth New York Volunteer Infantry during the Civil War and at its close brevet colonel, died at his home in Nunda, N. Y., September 3, from senile debility, aged 80.

Alexander D. Mackenzie, M.D. University of the State of Oregon Medical Department, Portland, 1894, of Portland, for several years secretary of the Portland Medical Association, died at St. Vincent's Hospital, Portland, from tuberculosis, August 25, after an illness of five months, aged 45.

B. Frank Park, M.D. Rush Medical College, Chicago, 1901, a member of the American Medical Association, a rising young physician of Omaha, and an instructor in the Omaha Medical College, died suddenly while making a professional call September 8, from cerebral hemorrhage, aged 28.

John H. Rhodes, M.D. Louisville (Ky.) Medical College, 1880, city physician of Jackson, Miss., a member of the State Board of Health, and president of the Jackson Sanitarium, died suddenly near his home in Jackson August 30, from heart disease, aged 45.

Charles C. Rubless, M.D. College of Physicians and Surgeons in the City of New York, 1873, for many years health officer of Morrisville, Vt., died at his home in that place September 11, from diabetes, after an illness of several years, aged 53.

Thomas Gilfillan, M.D. Berkshire Medical College, Pittsfield, Mass., 1855, a member of the Massachusetts Medical Society, and a surgeon in the army during the Civil War, died at his home in Northampton, Mass., September 9, aged 75.

Samuel Jackson, M.D., assistant surgeon United States Navy, commissioned in 1838 and retired in 1879, with rank of commodore, died at his home in Washington, D. C., July 22, from apoplexy, after an illness of two weeks, aged 88.

Gustavus A. Richardson, M.D. New York University, New York City, 1875, Hyattsville, Md., died at the Railroad Y. M. C. A. Hospital, Hagerstown, Md., September 1, from nervous collapse after an illness of several weeks, aged 60.

Thomas W. Poole, M.D. University of the Victoria College, Coburg, Ont., 1865, said to have been the oldest practitioner and once mayor of Lindsay, Ont., died at his home in that place August 28, after a lingering illness, aged 74.

E. Algo Donmyer, M.D. Baltimore Medical College, 1896, of Herington, Kan., while riding on a freight train near Enterprise, Kan., September 7, lost his balance, fell from the train and broke his neck, causing instant death.

Isaac Emmett Nicholson, M.D. Bellevue Hospital Medical College, New York City, 1894, died at his home in Oakland September 9, from cerebral embolism following typhoid fever, after an illness of two weeks, aged 34.

Frederick T. Lape, M.D. College of Physicians and Surgeons, Baltimore, 1896, formerly of Poughkeepsie, N. Y., died at the home of his parents in Athens, N. Y., September 4, from tuberculosis, after a long illness, aged 29.

Hugh L. Tobin, M.D. Jefferson Medical College, Philadelphia, 1880, twice physician at the state penitentiary, Frankfort, died from inflammation of the bowels at Pope Sanitarium, Louisville, September 14, aged 44.

James C. Lovejoy, M.D. Rush Medical College, Chicago, 1848, a pioneer settler of Greene County, Iowa, died at his home in Rippey, Iowa, September 6, from cerebral thrombosis, after an illness of two weeks, aged 87.

James W. Karr, M.D. University of Louisville Medical Department, 1848, a resident of Hickory Withe, Tenn., for 72 years and a practitioner in that place for 55 years, died at his home August 27, aged 79.

Christopher C. Jacobs, M.D. Bellevue Hospital Medical College, New York City, 1886, a member of the Medical and Chirurgical Faculty of Maryland, died at his home in Frostburg, Md., September 12, aged 54.

Eugene William Dickinson, M.D. St. Louis, 1891, formerly an attendant at the Topeka State Hospital, died in Topeka, Kan., September 6, after an illness of fourteen hours, from apoplexy, aged 33.

Dennis Lincoln Russell, M.D. Rush Medical College, Chicago, 1872, assistant surgeon during the Civil War, died at his home in Rushville, Ill., September 5, after a long illness from dropsy, aged 70.

John Jay Richards, MD. Medico-Chirurgical College, Kansas City, Mo., 1901. formerly of Agra, Okla., was accidentally shot and killed while hunting near Nevada, Mo., September 7, aged 28.

Rebecca Barnard, M.D. Woman's Medical College of the New York Infirmary, New York City, 1878. died recently at her home in Worcester, Mass., and was buried September 12.

Samuel C. Beard, M.D. University of Virginia Medical Department. Charlottesville, 1853, died at his home in Lewisburg, W. Va., from disease of the stomach, August 26, aged 73.

John N. Dunlap, M.D. University of Virginia Medical Department, Charlottesville, 1843, a pioneer physician of Saline County, Mo., died at his home in Miami, August 27.

Ernest Fruh, M.D. Jefferson Medical College, Philadelphia, 1886. of Philadelphia, died suddenly in a street car in that city September 7, from heart disease, aged 53.

Albert Koebig, M.D. University of Strasburg, Germany, 1873, while despondent, shot himself through the heart at his home in Houston, Texas, August 30, aged 64.

Orville C. Nally. M.D. Western Pennsylvania Medical College. Pittsburg. 1900. died at his home in Stotesbury. Mo., September 6, from typhoid fever, aged 32.

Thomas S. Allan, M.D. Hospital College of Medicine, Louisville, 1882, died from consumption at his home in Bloomingdale, September 11.

Deaths Abroad.

K. Schweigger, M.D., the successor of von Graefe as professor of ophthalmology at Berlin, died at Berlin August 23, aged 75. He retired from his official post on account of ill health in 1900. He published the *Archiv f. Augenheilkunde* and numerous text-books and special articles, and his perimeter and method of advancement, resection of the optic nerve and modification of cataract operations ensure him a prominent place in the history of ophthalmology.

O. v. Bungner, M.D., director of the Hanau Hospital and author of numerous articles on various branches of surgery and general pathology, died at Hanau, August 27, aged 47. One of his latest works was the collecting of data in regard to the importance of injuries of the tissues in the etiology of tumors.

Book Notices

Treatise on Orthopedic Surgery. By Edward H. Bradford, M.D., Surgeon to the Boston Children's Hospital, Consulting Surgeon to the Boston City Hospital, Professor of Orthopedic Surgery, Harvard Medical School, and Robert W. Lovett, M.D., Surgeon to the Infants' Hospital and to the Peabody Home for Crippled Children, Assistant Surgeon to the Boston Children's Hospital, Assistant in Orthopedic Surgery, Harvard Medical School. Third Edition. Illustrated by 592 engravings. Cloth. Pp. vi-669. Price, $5.00 net. New York: William Wood & Company. 1905.

This edition differs from the edition published six years ago chiefly in arrangement, improved illustrations, and in the chapters on congenital dislocation, scoliosis, and coxa vara, as it is especially in these subjects that recent advance has been made. It is noteworthy that one of the authors has been a large contributor to this advance in congenital dislocation of the hip, while the other has borne the same relation to scoliosis; *the sections on these subjects, therefore, are authoritative.*

Diseases of the Heart. A Clinical Text-Book for the Use of Students and Practitioners of Medicine. By Edmund H. Colbeck, B.A., M.D., B.C. (Cantab); F.R.C.P. (London); D.P.H. (Cantab), Physician to Out-patients at the City of London Hospital for Diseases of the Chest. With 43 Illustrations. Second Edition, Revised and Enlarged. Cloth. Pp. 350. Price, $2.50. Chicago: W. T. Keener & Co. 1905.

This book is an unusually complete and clear description of the heart and its diseases. Although small, the book is so concisely written that it contains an unusually large amount of information. It can be praised quite as much for its good arrangement, clearness and accuracy as for its fullness.

The Intestinal Catarrhs, Being a Clinical Study of Colitis, Appendicitis and Their Allies: with a Special New Section on Sprue. By Edward Blake, M.D., Member of the Royal College of Physicians. Second Edition. Cloth. Pp. 356. Price, $2.00 net. Chicago: W. T. Keener & Co.

This book is full of interesting scraps of information, but it is most loosely constructed. As a treatise on intestinal catarrhs it is a failure. Almost every page is padded with such sentences as these: "But as in politics, my country first, afterwards my party. So in pathology, truth first, with the utmost tolerance of catholicity; then a view held with a loose hand."

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending September 16:

Ford, Clyde S., asst. surgeon, reports on temporary duty at Fort McPherson, Ga., since September 6.

Morris, E. R., surgeon, on arrival at San Francisco, from Manila, P. I., ordered to Fort Slocum, N. Y., for duty.

Shepard, John L., asst. surgeon, left Army General Hospital, Presidio of San Francisco, on thirty days leave of absence.

Davis, Wm. B., deputy surgeon general, and Corbusier, Wm. H., deputy surgeon general, relieved from duty in the Philippines Division, to take effect October 15, 1905, and January 15, 1905, respectively.

Havard, Valery, asst.-surgeon general, Borden, William C., surgeon, and Gandy, Charles M., surgeon, are detailed to represent the Medical Department of the Army at the Fourteenth Annual Meeting of the Association of Military Surgeons of the United States, at Detroit, Mich., September 26-29.

Asst. Surgeons Samuel E. Lambert, Wm. H. Moncrief, Wm. T. Davis, Charles F. Morse, Clarence H. Connor, Nelson Gapen, Louis C. Duncan, and Philip W. Huntington (Dec. 15, 1905), Cary A. Snoddy, Samuel J. Morris, Harry S. Purnell, John W. Hanner, Horace D. Bloombergh, and Leon T. Lewald (Jan. 15, 1906), and Robert L. Carswell (Feb. 15, 1905), are relieved from duty in the Philippines Division, and will proceed to San Francisco on the transports sailing from Manila, on or about the dates designated after their names.

Asst. Surgeons William Roberts, Fort Hamilton, N. Y., Frank C. Baker, Presidio of Monterey, Cal., Robert M. Blanchard, Fort Thomas, Ky., William E. Vose, Fort Sheridan, Ill., Frank T. Woodbury, Plattsburg Barracks, N. Y., Edmund D. Shortlidge, Army and Navy General Hospital, Hot Springs, Ark., George F. Jeunemann, Fort Ringgold, Tex., De Loffre, Samuel M., Fort Schuyler, N. Y. (Nov. 5, 1905), Wal [illegible] on, Wash., James F. Edwards, Fort [illegible] ce DeWitt, Fort Washakie, Wyo., Rob [illegible] Wash., Charles R. Reynolds, Army G [illegible] Barracks, D. C., Frederick A. Dale, F [illegible] cAndrew, Patrick H., Jefferson, Barrack [illegible] W. Williams, Fort Greble, R. I., James I [illegible] Jan. 5, 1906), are relieved from duty at the stations designated after their respective names, and will proceed to the Philippine Islands for duty, on the transports sailing from San Francisco on or about the dates specified.

McCall, James H., contract surgeon, leave of absence extended twenty days. Relieved from further duty at Fort Moultrie, S. C., and ordered to his home, Huntingdon, Tenn., for annulment of contract at expiration of leave of absence.

Lemmon, Robert, c [illegible] McKinley, Me., and arrived at Fort War [illegible] duty.

Vaughan, Milton, [illegible] from duty at Fort Crook, Neb., and ord [illegible] ock, Ark. for annulment of contract.

Gardner, Fletcher, contract surgeon, granted an extension of twenty-four days to his leave of absence.

Koyle, Fred T., contract surgeon, granted leave of absence for one month.

Carpenter, Alden, dental surgeon, left Vancouver Barracks, Wash., on detached service to Fort Liscum, Alaska.

Kennedy, James S., contract surgeon, will, on abandonment of Fort Grant, Ariz., proceed to Fort Omaha, Neb. for duty.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending September 16:

Waggener, J. R., medical director, detached from the Navy Yard, Mare Island, Cal., and ordered home to wait orders.

Anderson, F., Medical Inspector, detached from the Marine Barracks, Washington, D. C., September 12, and ordered to the Navy Yard, Mare Island, Cal., for duty as Medical Officer of that yard and in command of the Naval Medical Depot.

McClurg, W. A., medical inspector, detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to the Marine Barracks, Washington, D. C., September 18.

McCormick, A. M. D., surgeon, ordered to the Naval Academy.

Lowndes, C. H. T., surgeon, detached from the Naval Academy and ordered to the *Texas*.

Dunn H. A., P. A. surgeon, ordered to the Naval Proving Ground, Indian Head, Md., September 15.

The following assistant surgeons have been ordered to report at the U. S. Naval Medical School, Washington, D. C., September 30, for course of instruction: F. M. Shook, G. M. Olson, R. A. Warner, F. H. Brooks, E. O. J. Eytinge, P. R. Stahlnaker, F. S. Sellers, C. D. Munger, B. Elmore, H. T. Nelson, N. S. Hathaway, J. B. Mears, E. R. Marshall.

Farwell, R. G., asst.-surgeon, detached from the Brooklyn and ordered to duty on the second torpedo flotilla on the *Worden*.

Hart, G. G., acting asst.-surgeon, ordered to the *Glacier*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending September 13.

Banks, C. E., surgeon, to proceed to Montgomery, Ala., for special temporary duty.

Guiteras, G. M., surgeon, granted leave of absence.

Rosenau, M. J., P. A. surgeon, to proceed to New Orleans for special temporary duty in connection with the investigation of the cause of yellow fever.

Stansfield, H. A., P. A. surgeon, relieved from duty on Isthmus of Panama, effective August 23.

Stansfield, H. A., P. A. surgeon, to report to the director of the Hygienic Laboratory, Washington, D. C., for duty.

Trotter, F. E., P. A. surgeon, to rejoin his station, San Francisco, Cal.

Sweet, E. A., asst.-surgeon, relieved from duty at New Orleans and directed to proceed to Fort Stanton, N. M., for duty and assignment to quarters.

McMahon, R. L., acting asst.-surgeon, granted leave of absence for thirty days from August 15.

Marsh, W. H., acting asst.-surgeon, granted leave of absence for twelve days, from September 19.

Mason, W. G., acting asst.-surgeon, granted leave of absence for nine days from September 16.

Quigley, F. L., acting asst.-surgeon, granted leave of absence for seven days, from September 4, under paragraph 210 of the regulations.

Rodman, J. C., acting asst.-surgeon, granted leave of absence for one and one-half days, from September 13.

Safford, M. V., acting asst.-surgeon, granted leave of absence for three days, from August 29, under paragraph 210 of the regulations.

Sill, R. H., acting asst.-surgeon, granted leave of absence for seven days, from September 30, under paragraph 210 of the regulations.

Walerius, M., pharmacist, granted leave of absence for seven days from September 2, under paragraph 210 of the regulations

Society Proceedings

COMING MEETINGS.

American Public Health Association, Boston, September 25-29

Medical Society of the State of Pennsylvania, Scranton, September 26-28.

Association of Military Surgeons of the United States, Detroit, Mich., September 26-28.

American Roentgen Ray Society, Baltimore, September 28-30.

Colorado State Medical Society, Colorado Springs, October 3-5.

American Association of Railway Surgeons, Chicago, October 4-6.

Idaho State Medical Society, Boise, October 5 6.

Delaware State Medical Society, Wilmington, October 10.

Mississippi Valley Medical Association, Indianapolis, October 10-12.

Vermont State Medical Society, Burlington, October 12-13.

New York State Medical Association, New York City, October 16 19.

Kentucky State Medical Association, Louisville, Oct. 18-20.

AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY.

Tenth Annual Meeting, held at Buffalo, N. Y., Sept. 14-16, 1905.

Under the Presidency of Dr. Hanau W. Loeb, St. Louis.

Officers.

The following officers were elected: President, Dr. Casey A. Wood, Chicago; vice-presidents, Drs. J. A. Stucky, Lexington, Ky.; Alvin A. Hubbell, Buffalo, N. Y., and Emil Mayer, New York; secretary, Dr. George F. Suker, Chicago (re-elected); treasurer, Dr. Otto J. Stein, Chicago (re-elected).

The place of next meeting will be decided by the council.

An address of welcome was delivered by Dr. Walter D. Greene, commissioner of health of Buffalo, which was responded to by the president.

President's Address.

President Loeb, after referring to the rapid rise of specialism, its divisions and subdivisions, devoted the rest of his remarks to the medicolegal aspects of certain cases of diseases and injuries and complications of the nose, throat and ear. The physician is called on to give his opinion and advice in certain cases as an expert in court. There are essential differences between the testimony of experts and that of ordinary witnesses. Fractures of the nose or involvement of the accessory sinuses may be the bone of contention in court. He cited several cases in point.

Vice-president's Address.

Dr. Derrick T. Vail, Cincinnati, first vice-president, spoke of the medicolegal aspects of ophthalmologic cases, and said that expert testimony implied an accurate and detailed knowledge of the science of ophthalmology coupled with abundant practical experience, and a complete understanding of the plaintiff's condition. He cautioned against examining patients cursorily, as this may lead to a wrong diagnosis. Illustrative cases were cited. Every tissue and organ of the body should be carefully examined before expert testimony is given in court in regard to a given case. Cases of simulation call for great skill on the part of the oculist. He pointed out and emphasized the importance of the expert using simple language in court. Answers to questions should be short, pointed and given in understandable English at all times, if possible.

(To be continued.)

MEDICAL SOCIETY OF THE MISSOURI VALLEY.

Annual Meeting, held in Council Bluffs, Iowa, Aug. 24-25, 1905.

The President, Dr. S. Grover Burnett, Kansas City, in the Chair.

Dr. S. Grover Burnett, in his presidential address, entitled "Oslerism Bearded, or a Study of Age in Relation to Work," called attention to the fact that Dr. George M. Beard was entitled to priority in suggesting the uselessness of men above 40 years of age. Papers were read by Drs. Leroy Crummer, A. C. Stokes, W. O. Bridges, A. P. Condon and J. P. Lord, of Omaha; Fenton B. Turck and W. F. Waugh, of Chicago; Daniel Morton, St. Joseph; J. W. Kime, Fort Dodge, Iowa; Herman E. Pearse and C. H. Hardin, of Kansas City; T. M. Bogart, of Excelsior Springs, Mo.

On Thursday evening the society was entertained by the local profession at Lake Manawa.

An amendment to the constitution was read, changing the annual meeting to the first Thursday in September.

The secretary's report showed a healthy condition of the society, 41 new members having been added during the year.

The Buchanan County Medical Society extended an invitation to hold the next semi-annual meeting in St. Joseph in March, 1906, which was accepted.

Election.

The election of officers for the ensuing year resulted as follows: President, Dr. John E. Summers, Jr., Omaha; vice-presidents, Drs. C. H. DeWitt, Glenwood, Iowa, and C. B. Hardin, Kansas City, Mo.; treasurer, Dr. Donald Macrae, Council Bluffs (re-elected); secretary, Dr. Charles Wood Fassett, St. Joseph, Mo. (re-elected).

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Burns.

Van Zandt, in *Amer. Pract. and News*, states that nervous shock is the chief cause of death following burns if it occurs early. If the patient survives the first stage general intoxication is the chief factor, or death may occur from an intercurrent disease such as pneumonia, Bright's disease, erysipelas, pyemia, etc. A burn is a wound and demands as careful attention as a wound from any other cause, and the earlier a burn is dressed the better will be the results.

The alleviation of pain is the first thing to be given attention. In burns of the first degree, according to the author, this is best accomplished by dusting the parts with some alkaline powder or by lead water compresses or collodion dressing. If the burn is of the second or third degree it becomes a more serious proposition. Therefore, in selecting a dressing for burns two principles must be considered: The agent must cause no irritation and it must be antiseptic. After cleansing the surrounding skin and irrigating it with a 1 to 1,000 bichlorid solution or a 3 per cent. carbolized solution, the surface should be syringed with a solution of hydrogen peroxid (one part to six of water). The dangers from the use of poisonous antiseptics must be kept in mind. When the burn is extensive this author recommends dressing it by applying strips of rubber tissue one-half inch wide all over the surface of the injured area and extending well over the edges to the sound skin, and over this sterilized gauze and a bandage. When granulations are well started skin grafting is recommended.

In extensive burns the water bath of Hebra is advised, as it does away with the pain of changing dressings.

In burns of limited extent a protective dressing with carron oil, olive oil, white of egg, ichthyol (2 per cent.), resorcin, applied on pieces of sterilized gauze, is recommended.

Picric acid is also mentioned as of service in different strengths, applied early in the disease before granulation begins. It is said to deaden the pain. The author, however, prefers the following combination for burns of any degree:

℞. Aluminis .... ℥i 30|
Acidi carbol..................... ʒi 4|
Ichthyol .... ʒiiss 10|
Liq. petrolati q. s. ad.............. ℥vi 180|
M. Ft. unguentum. Sig.: Apply locally.

[The foregoing is put in prescription form on the author's statement that he uses alum 15 per cent., carbolic acid 2 per cent., and ichthyol 5 per cent., in liquid petroleum as a base.]

In any case the author advises against dressing the wound too frequently unless there are special indications for it. He is opposed to dusting powders of any sort when the burn is beyond the first degree, because they are irritant in their action and tend to increase the amount of the discharge. The granulations forming over the burned areas must be protected and a perfectly healed wound will be the result, and there will be no deformity from the scar and no loss of function from contraction. The constitutional treatment consists of supporting measures and analgesics if required.

Meyers claims that it is bad surgery to cleanse any burn unless it contain sawdust. By scrubbing a burn the clots which have formed are removed and the wound then presents a good field for infection.

Block recommends a saturated solution of picric acid on cotton as a local application and close observation of the kidneys.

The following combinations are recommended by other authorities for local applications in the treatment of burns:

In burns of the first degree:

℞. Acidi carbol..................... ʒss 2|
Olei lini
Aquæ calcis, ãã.................. ℥iv 120|
M. Sig.: Shake well and apply on lint. Or:

℞. Acidi picrici..................... ʒss 2|
Alcoholis .... ℥i 30|
Aquæ dest. .... ℥xii 360|
M. Ft. solutio. Sig.: Bathe the parts well with the solution, and follow it by an application of the solution on cotton. Or:

℞. Ext. opii..................... gr. viiss |50
Ichthyoli .... ʒiv 15|
Liq. petrolati
Lanolini, ãã..................... ʒvi 24|
M. Sig.: Apply locally on gauze in burns of the first degree.

In burns of the third degree *Merck's Archives* recommends the following:

℞. Ichthyoli .... m. xlv 3|
Olei olivæ .... ʒii 8|
Lanolini .... ℥iii 90|
M. Sig.: Apply locally. Or:

℞. Olei amygdalæ exp.
Aquæ calcis
Lanolini, ãã .... ℥iii 90|
M. Sig.: Apply for two days, two or three times daily, and follow with:

℞. Aquæ plumbi .... ʒv 20|
Liq. petrolati .... ʒiv 15|
Lanolini .... ʒi 4|
M. Sig.: Apply freely once daily.

In cases accompanied by excessive pain the following is recommended:

℞. Cocainæ hydrochlor..................... gr. x |65
Liq. petrolati .... ʒiii 12|
Lanolini .... ʒii 8|
Aquæ dest. .... ʒv 20|
M. Sig.: Apply freely on the painful surface.

Iron Acetate in Pneumonia.

Robson, in *British Med. Jour.*, recommends the following combination, containing the acetate of iron, in the treatment of pneumonia:

℞. Liq. ferri chloridi..................... m. xv 1|
Liq. ammon. acetatis..................... ʒii 8|
Aq. chloroformi .... ℥ss 15|
M. Sig.: One such dose every four hours in water.

It may be given alternately every six hours with a mixture containing strychnia, as follows:

℞. Liq. strychniæ (1 per cent.)............ m. v |30
Aq. chloroformi .... ℥ss 15|
M. Ft. mistura. Sig.: One such dose every six hours.

The foregoing treatment should be kept up until the crisis has passed. He does not recommend quinin or antipyretics, and seldom prescribes digitalis. He recommends the treatment above outlined in severe cases of bronchopneumonia occurring in infants and children, and in catarrhal and lobar pneumonia occurring in debilitated patients.

Delirium Tremens.

In cases of delirium tremens, when the patient has reached the stage of alcoholic indulgence characterized by insomnia, great excitability and inability to retain food, the *Medico-Chirurg. Jour.* recommends that an active cathartic similar to the following be administered:

℞. Pulv. jalapæ co..................... gr. x |65
Hydrarg. chloridi mitis
Sodii bicarb., ãã..................... gr. v |30
M. Chart. No. i. Sig.: To be taken at one dose.

Should the heart show any signs of weakness the following is recommended:

℞. Tinct. capsici
Tinct. digitalis, ãã..................... ʒiv 15|
Tinct. nucis vom..................... ʒii 8|
Spts. ammon. arom. q. s. ad.......... ℥iii 90|
M. Sig.: One teaspoonful in water every four hours.

In cases of extreme nervousness accompanied by insomnia, sedatives will be required, and in extreme cases a hypodermic of morphin.

Hyperidrosis.

The following combinations after Unna are recommended by the *N. Y. Med. Jour.* in the treatment of hyperidrosis:

Wash the affected parts with spirits of camphor or with weak solutions of vinegar and follow it with a local application similar to the following:

℞. Ichthyoli
Spts. terebinthinæ, ãã..................... ʒv 20|
Ung. zinci oxidi .... ʒx 40|
M. Ft. unguentum. Sig.: Apply locally on retiring.

In the shoes the following may be sprinkled:

℞. Pulv. sinapis .... ʒi 4|
Pulv. talci..................... ℥iv 120|
M. Ft. pulvis. Sig.: To be dusted in the shoes.

When the hands alone are affected a half-teaspoonful of the following may be thoroughly rubbed into the hands after washing them:

℞. Tinct. belladonnæ..................... ℥ss 15|
Spiritus oderatus .... ℥iii 90|
M. Sig.: One-half teaspoonful to be rubbed into the hands two or three times a day.

Medicolegal

Immaterial Consultations of Physicians.—The First Appellate Division of the Supreme Court of New York says that the applicant for the life insurance sued for in the case of Valentini vs. Metropolitan Life Insurance Company stated that a certain physician was the one who last attended him, in 1898, for rheumatism, and that he had not been under the care of his physician within two years, unless as stated in previous line. His mother was named as beneficiary. And the consultation of another physician by the mother without the knowledge of the son, or a consultation with his knowledge when he was not suffering from any ailment or disease, the court holds, would not constitute either of his answers a breach of warranty. Again, the court says that it was manifest that a breach of warranty was not established as a matter of law. Assuming that the attendance of the other physician was within two years of the time when the answers were given, yet it was not made to appear that the assured was afflicted with any disease which called for medical attendance, or that it was other or different than a mere fear engendered in the mind of the mother that the son was in need of some medical attendance. It was made affirmatively to appear that the trouble at the most was a slight nervous twitching, which did not interfere with the physical vigor of the insured, or with his ability to attend to his business. The purpose of the question and answer was to inform the company as to the physical condition of the applicant and his probable duration of life and before the court is justified in holding that there is a breach of warranty it must appear that attendance by a physician had been for some substantial disorder, and not for a mere functional and temporary indisposition. This the evidence failed to establish, and the court was not, therefore, justified in determining the question as matter of law.

A Supreme Court on a Low Age of Consent.—The Supreme Court of Mississippi takes occasion, as it says, in Dickey vs. State, to express its opinion concerning the wisdom and justice of the conclusive presumption of law (as apparently at present in that state) that a female child over the age of 10 years has sufficient intelligence and discretion to consent to the surrender of her virtue and the defilement of her person. Every child under 14, the court declares, is presumed by the law to be incapax doli (that is, mentally incapable of entertaining a criminal intent), because presumed not to have developed sufficient intelligence and moral perception to distinguish between right and wrong and to comprehend the consequences of his act. And hence no child under 14 can be punished for any crime except on proof of exceptional intelligence and maturity. And yet, while this is true, and while it is further true that a female child less than 10 years old, by so much as a day, is conclusively presumed incapable of consenting to sexual commerce, a female child over 10, by so much as a day, is conclusively presumed capable of consenting to the sacrifice of her virginity, her social undoing and her moral ruin. This, the court supposes, by analogy, is because she is presumed to have sufficient intelligence and moral discrimination to distinguish between right and wrong, and to comprehend the ruinous consequences of the act. This presumption is inconsistent with the presumption of incapacity to commit crime, and in irreconcilable conflict with the truth, and is an insult to our intelligence. We all know that the overwhelming majority of the girls of this state under 14 years of age, in their ignorance and innocence, do not and can not have any adequate understanding of sexual commerce, nor any comprehension of the ruinous consequences of a lapse from virtue. The legal presumption which declares that every female over 10 years of age is fully capable of giving intelligent assent to her own ruin, and which, therefore, make her fair play for any lecherous scoundrel who can impose on her innocence and credulity, is a reproach to the law, a disgrace to a Christian state, and a blot on the civilization of the age. The girls of the state under 14 should be protected by a legal presumption that they are incapable of consenting to their own shame. This presumption might be made either prima facie or conclusive. If prima facie, it might be allowed to be rebutted on proof of exceptional intelligence and maturity. If conclusive, the penalty might, in the discretion of the trial court, be made either death, imprisonment for life, or imprisonment for a term. In this way, without injustice to any one, our daughters could be protected by the law until such time as they could reasonably be presumed to have sufficient discretion to protect themselves against the machinations of the seducer.

Physician Competent to Give Certain Opinion Evidence.—The Supreme Court of New Mexico says, in Miera vs. Territory, that opinion evidence is not, in its nature, so distinct from and inferior to what is usually termed direct evidence as it is, perhaps, commonly assumed to be. In the last analysis all testimony may fairly be termed opinion evidence, and the court may properly act on the familiar principle that the best evidence should be offered. Unquestionably, in many cases so-called opinion evidence would be more helpful than any direct testimony obtainable. and that for two reasons: First. It may be the testimony of one to whose sight, hearing or other senses has been presented that which can not be reproduced to the jury. It is said in opposition to the admission of such testimony that the facts should be stated to the jury, and the opinion formed by it. But not even the great masters of literature have been able to put in words precisely what they saw, still less what was apprehended by their other senses. In recognition of this truism courts have permitted witnesses to state their opinions with regard to sounds, their character, from what they proceed, and the direction from which they seem to come; as to resemblance of foot tracks; whether a person's conduct was insulting; and where noisome odors render a dwelling uncomfortable, etc. Second. The opinion may be that of a person qualified by study or experience, or both, to understand and explain the subject under consideration, commonly termed an "expert." The opinions of such witnesses are taken in all courts on a great variety of subjects, but not usually on the question whether death was self-inflicted. In State vs. Lee, 65 Conn. 265 (1894), however, and in Commonwealth vs. Leach, 156 Mass. 99, the testimony of a physician was admitted on that point; but in each of those instances the wound testified of was in the uterus, to procure abortion, and it might be said that if it had been an outward wound, open to common observation, the testimony would have been rejected. That objection, it seems to this court, goes to the weight, and not to the admissibility, of such testimony. Physicians have been allowed to testify that sexual intercourse was highly improbable, if not impossible, between a man and a woman in a buggy, which was described to the jury (People vs. Clark, 33 Mich. 1122); that such intercourse by force was impossible with a woman seated in a rocking chair, which was shown to the jury (State vs. Perry, 41 W. Va. 641); and that it was impossible in a winding stairway, which was described to the jury (McMurrin vs. Rigby, 80 Iowa, 322). Certainly it can not be claimed that wounds causing death are more a matter of common knowledge than the act to which the human race owes its continuance. In 41 W. Va. the admission of the testimony in question was put expressly, and in the other cases impliedly, on the ground that the witnesses "had made the human system, including its joints and organs, the subject of peculiar study, such as a jury would be unable to give in the short time allowed them in the examination of the evidence, and thus [could] assist them in arriving at a just conclusion." Precisely that kind of research would qualify one to determine better than an ordinary person could do whether a wound could have been self-inflicted. And this court holds that an experienced physician, who held an inquest on the body of the woman with whose murder the defendant was charged, was properly permitted to testify that, in his opinion, she could not have inflicted on herself the wound of which she died, and that she was sitting down when the shot was fired. To exclude such testimony, it says, is to hold that the opinion of a jury, based on evidence necessarily incomplete, is preferable to that of a man of learning and experience, who has seen and touched that of which he speaks. The value of the physician's opinion was for the jury to determine. If it preferred to form and adopt an opinion of its own on the other evidence given it was at liberty to do so.

2 *Deforn [illegible] G. G. Davis, Philadelphia.
3 Therapeutic Value of the Digestive Ferments. H. W. Bettmann, Cincinnati, Ohio.
4 *Repair of the Genital Tract Following Labor. F. C. Hammond, Philadelphia.
5 *Iron Precipitates in the Blood, Spleen and Red Marrow. E. T. Williams, Boston, Mass.
6 *Technic of Pelvic Examination and the Principles of Local Pelvic Medication. E. A. Schumann, Philadelphia.
7 *Advantages of Sanatorium Treatment of Tuberculosis. F. M. Pottenger, Los Angeles, Cal.

1. **Difficulties in Abdominal Diagnosis.**—Montgomery cites the history of six cases, illustrating some of the difficulties, which may be divided into those in which the solution has to do with the existence or non-existence of pregnancy; those in which ovarian tumors may be in question; those in which doubt occurs as to the presence of a myoma, and those in which there is uncertainty as to the existence of other growths.

2. **Deformities of the Lower Extremity.**—According to Davis, the main characteristic of these deformities is weakness. This may be either a weakness affecting the constitution and tissues of the body generally, or it may be a local weakness, or it may be both combined. He divides the cases into three classes: (1) Those due to rickets; (2) those due to paralyses, and (3) those due to deformities of the feet. In these three groups are included most of the deformties of the lower extremities, their diagnosis, prognosis and treatment being considered in detail.

4. **Repair of Genital Tract Following Labor.**—Hammond emphasizes the importance of a thorough examination by inspection, with a good light, of the genital tract, as a routine measure on the termination of labor. Repair of lacerations should be done within twelve hours, if the condition of the patient permits. The technic of suturing the various lacerations is thoroughly detailed.

5. **Iron Precipitates in the Blood, Spleen and Marrow.**—Williams found iron precipitates in healthy spleens, in marrow and in healthy blood. He believes the gastric juices extract this iron from the food in the form of a chlorid, which combines with the peptones in the stomach to form a peptonoid. Thence it passes into the portal vessels and spreads through the system. A large amount of it is plainly deposited in the spleen and marrow, where it is intended to serve as pabulum for the young red blood corpuscles.

6. **Pelvic Examination and Medication.**—Schumann says that in all cases involving abdominal section or in which an accurate diagnosis is at all difficult two examinations should be made at least twenty-four hours apart. Inspection is an important and frequently neglected portion of the diagnostic technic and should not be omitted save in cases of extreme delicacy on the part of the patient. Rectal touch, particularly in the knee-chest position, is of great value in determining obscure affections of the pelvic organs. Local treatment, especially the use of the hot vaginal douche, is described at length. The douche should be given at least twice daily, morning and evening, and its administration should last perhaps a half-hour—certainly not less than fifteen minutes. The temperature of the water should be as high as may be comfortably borne by the patient. It may be increased from day to day to 100, 110, 115 and even 120 F. Its use should be continued for over a long period of time, months, and sometimes even years. Long-continued use is essential to the success of the procedure. Too long-continued use, however, of the douche in the normal vagina must never be practiced, since the washing out of the normal vagina of lactic acid bacteria, whose function is to render the vaginal secretion acid and an unfit culture medium for most pathogenic bacteria, renders the passage of such organisms to the higher pelvic organs comparatively easy.

7. **Advantages of Sanatorium Treatment of Tuberculosis.**—Pottenger believes that patients can be treated best in a sanatorium, because (1) they are under the immediate and constant guidance and control of the physician who can see that they do the things which are necessary to help bring about a cure, and prevent them from doing things which tend to lower vitality and retard progress; (2) they are furnished with apartments suitably lighted and ventilated, and with food adapted to their needs and properly prepared; (3) they can be given the advantages of all scientific measures which have proved of value in treatment. Good food, fresh air and careful guidance are the basis of treatment, but the tuberculous individual is not receiving the best that can be had until we give him the benefit of all scientific aids, and of these especially to be recommended are hydrotherapy, the chemic rays, culture products, and direct medication of the upper air tract.

8. **Treatment of Sciatica.**—Leszynsky remarks that pain in the course of the sciatic nerve is common, but that genuine sciatic neuralgia is rare. Most of the cases are really perineuritis or interstitial neuritis, while others are symptomatic of interference with nutrition by some extrinsic lesion. The causes of sciatica are exposure to cold, overfatigue of the legs, and pressure on the nerve from habitual sitting in persons whose metabolic processes are impaired by rheumatism, gout, diabetes, or alcoholism, injuries from lifting heavy weights, horseback or bicycle riding, sewing-machine work, etc. Sciatic pain occurs in diseases of all neighboring organs that are associated with compression of the sciatic nerve or sacral plexus. Such are tumors and inflammation in the pelvis, or of the spinal meninges, vertebral caries, uterine disease, pregnancy, parturition, malignant disease of rectum, hemorrhoids, hardened feces, sarcoma of femur, etc. It may result from fracture or dislocation of the thigh. It is rare from lead, mercury, or syphilis. Anemia, chlorosis, and hysteria have little influence in producing it. It may develop suddenly from exposure, or slowly when symptomatic of other diseases. The diagnosis is based on pain or tenderness over the nerve trunk, which radiates to the foot or toes, and diminution or loss of the Achilles tendon reflex. When degenerative, it is accompanied by paralysis, atrophy, vasomotor disturbances, etc. In the treatment of sciatica the first thing is the diagnosis of the cause and its removal when possible. In acute cases heat by the hot wet pack, combined with rest and fixation, and hot saline enemata, relieve pain. The bowels should always be moved by enema, and calomel given to unload the bowel and eliminate poisons. Morphin or opium suppositories are always indicated to obtain sleep at night. Massage, if gentle, is useful. Linear cauterization is of value in relieving pain, as is the ice bag at times. The continuous galvanic current in either direction is useful at the end of one week. It is more useful in mild, subacute or chronic cases. Mild cases will yield to hot packs, massage, and rectal irrigation. In subacute or chronic cases a modified rest cure is essential. Drugs are useless. Daily massage and passive movements and systematic exercises are useful. Hydrotherapy, in form of local wet pack, Scotch douche, etc., is most valuable. Static or faradic electricity in the form of the brush is useful.

9. **Methods of Modifying Milk for Infant Feeding.**—Pisek classifies the principles involved in the methods of feeding now in vogue, so as to show the effect of the use of these methods. Infants develop new functions during the suckling period, and change in form and function until the weaning period, after which growth is principally in size. The teeth in the child are absent, and the stomach is not like that of the adult. The digestive tract is developing and changing in functions, yet the

milk remains practically the same in composition throughout lactation. Hence the stomach as it develops changes the milk so as to make it suitable for its altered form and function. The digestive secretions change the milk, producing curds, and so supplying the solid constituents that are necessary to accustom the stomach to digestion of solids. A large factor in feeding is the gradual changing of diet. The proteids of colostrum are soluble. This is gradually displaced by proteids in the form of casein combined with calcium, which forms curds. The first secretion of the stomach is rennet ferment, which produces paracasein, a compound unaffected by pepsin. A small amount of acid secreted will produce free paracasein curd, which is digestible by pepsin. This is denser than the curd produced by rennet. More acid causes the free paracasein to combine with the acid and form chlorid of paracasein, digestible by pepsin. Thus the stomach may produce three solid compounds with casein of milk, having different forms and digestive properties, depending on the strength of the secretions. The author divides the methods of infant feeding into seven groups. The first group contains all methods that affect the quantitative composition of milk—dilution, with fat and sugar addition and whey and cream mixtures. To insure proper growth and development the infant needs as much tissue and energy foods as are found in human milk. The energy foods in cow's milk are in the same quantities as in human milk, but the tissue foods are in larger amounts. To reduce the quantity of proteids the milk is diluted, and to bring the energy and fat foods up to normal, sugar and fat must be added, otherwise the proteid must supply the energy. If this is not done the infant fails to gain in weight and strength as it should. If the amount of sugar is too great, as in condensed milk, the excess of energy food is converted into fat, and the child gains in weight; it is supposed to be growing, but in reality it is being stunted and deprived of its natural rights, for proteids are needed for true growths, as well as mineral salts for the bones. Whey feeding, with casein removed, can be used only temporarily, as it supplies no solid matter for the stomach to act on. The second group includes methods that inhibit rennet action and formation of curds by the use of alkalies. The normal reaction of mother's milk has been found to be acid. The alkalies prevent the formation of curd in the presence of soluble lime salts. The alkali is always in excess of the amount necessary to neutralize acidity. The effect of any alkali prevents the rennet action and retards the action of the gastric secretions. Group three includes methods that retard rennet action and neutralize the acid of the gastric juice. Here basic compounds are formed with the casein, and all gastric digestion is prevented. Enough alkali is used to neutralize sour milk. Group four consists of methods which precipitate casein by acids. If sufficient acid is present it combines with the free casein and produces an insoluble precipitate like that of sour milk. Group five includes methods that profoundly alter the character of the milk—peptonizing, adding citrate and oxalate of ammonium, potassium, or sodium. They all prevent formation of rennet curds; the milk remains fluid. Group six contains the methods that indirectly alter milk—sterilizing, Pasteurizing, boiling, etc. They prevent the action of the rennet ferment, or render it slower than normal. In group seven are placed the methods that alter the curds mechanically, as by addition of cereal gruels. The gelatinized starch of the gruel makes the curd of the milk softer and more easily digested.

10. **Kernig's Sign and Its Pathogenesis.**—Hassin draws the following conclusions regarding its causation: In Kernig's sign we have, first of all, to do with stretching of the sciatic nerve. In the healthy state this stretching seems not to produce any pathologic conditions; but in disease when the nerve itself is affected or the nerve roots are affected—which undoubtedly takes place in acute meningitis—the stretched, affected roots react correspondingly; the posterior roots by producing pain, and the motor roots by producing contraction of the corresponding muscles, in the case of the sciatic nerve, the flexor muscles. The pain arising from the stretching of the posterior roots makes the patient instinctively keep away from further stretching of the posterior roots, as it happens, for instance, in dislocations when the muscles respond with strong contraction to any active or passive movements in the dislocated joints, so that this explanation may be held, at least, as the simplest one we have for the understanding of the mechanism of Kernig's sign. The occasional occurrence of the sign in typhoid fever may be explained by the fact that the meninges are frequently affected in typhoid fever, so that the sign is due, not to the fever, but to the concomitant meningitis. Regarding other published cases in which Kernig's sign was present in the apparent absence of meningitis, it is hard to prove that in those cases the meninges were not affected, so that, commonly, Kernig's sign may be considered as a standard sign of inflammatory meningeal lesions, and as being due to irritation of the spinal roots, produced by the stretching of the sciatic nerve.

11. *Mechanics in Dorsal Pott's Disease.*—Schapps analyzes the factors concerned in the production of the deformity in dorsal Pott's disease, and lays particular stress on the sternal *protrusion. The weakest point is the front of the chest, and* without the sternal protrusion the spinal deformity can not possibly take place. During the earlier stages of the disease, *treatment in the recumbent position* by some such apparatus as the Bradford frame is necessary, and the best and quickest results are obtained by treating the spine with the same gentleness as if it were fractured or otherwise acutely affected. The upright position should be deferred until the acute stage has passed, and the change should be a gradual and careful experiment. Schapps points out the mechanical defects of the ordinary apparatus designed for use by these patients, and says that it is a fallacy to suppose that the spine can be fixed by a brace attached to the back. Other fallacies are belief in the efficiency of spinal leverage and the means of securing vertical relief. He then describes and illustrates his own form of apparatus, which consists of a set of anterior pelvic and pectoral supports designed to be attached to a Taylor back brace in such a way as to support the chest as well as the back. This he considers superior to the plaster jacket or its modifications in regard to both efficiency and cleanliness, while it is also adaptable for use in cases of cervical or high dorsal disease.

15. **Pancreatic Inflammation.**—Beck reviews the anatomy of the pancreas, especially its relation to the other abdominal organs, and discusses the clinical history of inflammations of that organ. He says that there is not one sign which is absolutely pathognomonic for pancreatitis. Only by carefully considering the history, the mode of the onset and the various combinations of the different symptoms can a diagnosis be made in most cases. He is convinced that pancreatitis is of much more frequent occurrence than is generally assumed, and that many cases, not only of the chronic, but also of the acute type, could be saved by surgical interference. The method of operating practiced by him is as follows: An incision is made alongside the outer margin of the rectus muscle. If a tumor was felt in the median line, the incision may reach from the xiphoid process to the umbilicus. If the rib arch proves to be in the way, Marwedel's method of resecting it may be advisable. *The further procedures* must bear an exploratory character. At first the ducts are inspected and palpated, in order to ascertain whether there be a calculus in the Wirsüngian or *the common duct, or in the papilla of Vater.* In this event, extraction of the calculus must be followed by duct drainage. If such steps are contemplated, large gauze pads must be ready to mop up the secretions as they escape. If there is a pancreatic exudation it must be discharged. During these manipulations the abdomen is frequently irrigated with hot sterile water. Beck regards the use of these simple *means* as very important in intra-abdominal operations, because they stop surface hemorrhage, permitting the surgeon to see more clearly. At the same time they *remove exudations and blood* clots in an easy, mechanical manner and eliminate, therefore,

a favorable soil for bacterial development. The repeated hot water irrigations, to a certain extent, also possess bactericidal properties. After the field is thoroughly cleaned, packing with 3 per cent. iodoform gauze is done. If the patient is in grave collapse, ether should not be given, and local anesthesia administered instead. In the subacute, or chronic form, the patient can always be given the benefit of a full general anesthesia.

16. **Care of Infant.**—Forest discusses the care of the mother during the pregnancy; the treatment of obstetric accidents; the hygiene of the infant and its nursing, and feeding during the first few days, until the milk comes.

17. **Pneumococcus as a Factor in Hemoptysis.**—Believing that the pneumococcus is the cause of hemorrhage in pulmonary tuberculosis, Flick, Ravenel and Irwin studied the ejected blood of a number of cases of hemorrhage. The pneumococcus was found present in all. In two of the cases there was a history of exposure to pneumonia in the one, and a history of exposure to another case of hemorrhage in the other. These two cases occurred in an institution in which four cases of hemorrhage occurred about the same time. The nurse who waited on the pneumonia patient came in contact with the other patients in the institution and waited on some of them.

20. **Smallpox in St. Louis.**—During the fiscal year beginning April 1, 1903, and ending March 31, 1904, 228 cases of smallpox were sent to quarantine by the St. Louis Health Department. Of this number, 188 were white persons and 40 colored; 156 were males and 72 were females; 179 persons contracted the disease in the city, and 49 elsewhere; 199 persons had never been vaccinated, 8 had faint scars and 21 had poor marks. Only one patient died. During the year beginning April 1, 1904, and ending March 31, 1905, there were 854 cases, 110 of this number developing in quarantine. Six hundred and thirty-six were white persons; 108 colored; 433 males and 311 females; 715 persons contracted the disease in the city, and 25 elsewhere. As to the vaccinal status, 622 persons had never been vaccinated; 5 had good scars; 30 had very faint scars, and 83 had poor marks. Eighty-seven patients died, a mortality percentage of 11.3. The scars in those who had previously been vaccinated ranged in age from fifteen to fifty years. In regard to the contagiousness of the disease, Scherck states that he does not believe that it can be carried by means of a third party who simply comes in contact with the patient. It had been the experience of the St. Louis Health Department that not a single case can be attributed to contagion carried by physicians, fumigators or others. Furthermore, Scherck does not believe that even those susceptible to the disease can contract it by visiting the rooms recently emptied of smallpox cases. Actual contact with the disease is the only source of contagion. He has also observed that at a certain distance from the patient the poison seems to be so much attenuated that it does not convey contagion. He has noticed that, even in tenement districts, where families live very close to the patient, they have not contracted the disease, while momentary actual contact with the patient has produced the disease at the end of the proper incubation period. He urges that a determined effort should be made by all health officers throughout this country to the end that a compulsory vaccination law shall be enacted for the purpose of stamping out the disease.

38. **New Operation for Anteflexion.**—Barrett describes a new method of hysteroplasty which he has been using for the correction of anteflexion and constriction at the internal os, whether muscular, fibrous or membranous, as follows: The uterus is first dilated, and, if necessary, curetted, and should great elongation of the cervix exist, the cervix is amputated. The abdomen is then opened in the median line, and the uterus is brought up and held with a tenaculum placed just above the flexion at the internal os. A longitudinal incision is now made over the internal os, its length corresponding with the extent that the posterior wall needs shortening in order to straighten the uterus. The author's tenaculum forceps is used to change this longitudinal slit into a transverse one, broadening the cervix, the length of the slit, and shortening the posterior walls to the same extent. A median suture is placed while the forceps holds the incision transversely, and at the same time holds the uterus up. The forceps is then removed and one or two sutures are placed on each side of the median suture as needed. This procedure allows the cut ends of the circular fibers to be displaced to the side so that they are from 1.5 to 2 cm. apart, outside measurement. The circumference of the uterus is thus materially increased, and the constriction obliterated. The incision may be carried as deep into the cervical tissue as may be desired, into the canal, in fact, if a membranous stricture exists. The incision, however, grows shorter as it goes inward toward the canal. In the absence of other pelvic lesions, and in cases with a sufficiently roomy vagina, the vaginal route might be chosen.

39 and 40. Id.—See The Journal, June 17, 1905, p. 1956.

43. **Modified Alexander Operation.**—Sandberg has devised a modification of Alexander's operation, to be employed in cases of retrodisplacement of the uterus complicated with prolapse of more than a moderate degree. An incision is made in the median line, above the pubis, three or four inches long, down to the fascia. The skin and adipose tissue are then, by blunt instruments, dissected loose from the fascia on the one side until the external ring of the inguinal canal is exposed. The flap of skin and adipose tissue being held aside by two blunt retractors, the round ligament is picked up, freed in the usual way, and secured by a strip of gauze. The same procedure is repeated on the other side. The abdomen is now opened in the median line, and intra-abdominal work carried out in the usual way. In case of prolapse of more than a moderate degree, the sacrouterine ligaments are shortened. This accomplished, the fundus of the uterus is brought well forward, the round ligaments are pulled out through the inguinal canal, and

the effect on the uterus is ascertained. The deeper layers of the abdominal incision, peritoneum, muscle and fascia are now sutured, the peritoneum by interrupted or continuous catgut sutures, the fascia by interrupted figure-of-eight silk sutures. After this the round ligaments are pulled out to the extent indicated by the previous test and fastened by silk sutures, four on each side, of which three are carried through the aponeurosis of the external oblique muscle and the round ligament, the fourth one securing the ligament to the fascia over the pubic bone. The skin and adipose tissue are then united by means of sutures or adhesive plaster strips, but leaving the wound open enough for free drainage. The advantages of the method are: 1. There is only one incision. 2. That this is located where it gives the best access for examination of the pelvic organs and for work in the pelvic cavity. 3. One opens the abdomen for exploration with much less hesitancy when all work can be accomplished through the same incision, and many of the causes of failure of the Alexander operation may be ascertained and avoided by an exploratory opening of the abdomen. 4. The intra-abdominal work is limited as much as possible, stitching of the uterus or the round ligaments intra-abdominally being avoided. 5. It leaves no adhesions or bands between the abdominal wall and the uterus to interfere with the expansion of the bladder, or growth of the uterus in pregnancy, or to cause obstruction of the bowels. 6. The intra-abdominal relations are left in a condition most closely resembling the normal. 7. The part of the round ligaments retained is the thickest and strongest.

44. Hematemesis from Gastric Ulcer.—Thompson studied about 200 cases of gastric ulcer with hematemesis with a view of formulating the indications for operation. The most interesting feature of these cases was the fact that considerably more than one-half of the patients were discharged as cured after serious hematemesis, which occurred either immediately before admission or during the patients' stay in the hospital, or both. The total deaths, numbering 41, present a ratio of one death to 4.8 cases. Included in the deaths which took place among the patients not operated on were several in which the ulcer was not the whole cause; thus 6 patients died from pneumonia, 1 with abscess of the pancreas, 1 with pyonephrosis, 1 with pyopneumothorax and 3 with a subphrenic abscess. One patient had a gastroureteral fistula. In 8 of the patients not operated on and in 3 of the 20 who were operated on, death occurred from the immediate effects of hemorrhage into the stomach, which at autopsy was found filled with blood. In one case, for example, the patient lost 80 ounces of blood, by actual measurement, during the three days that she was in the hospital prior to the operation. Twenty patients were transferred to the surgical division of the hospital for operation; of these 14 died and 6 were discharged as "cured." Of the 14 fatal cases 4 presented a septic peritonitis from perforation and were nearly moribund at the time of operation. Another, as stated above, was moribund from hemorrhage, a sixth was found to have a perforated duodenal (not gastric) ulcer, and a seventh proved fatal on the thirteenth day, a recent perforation having been disclosed at operation. None of these 7 cases, says Thompson, should, therefore, be considered as having any real bearing on the operative treatment of gastric ulcer, for they all presented a forlorn hope, 2 patients dying on the table and 4 within twenty-four hours. It appears that among the 20 patients operated on, the medical diagnosis was erroneous five times, there being 1 case of tuberculosis of the stomach, 1 of perforating duodenal ulcer, and 3 in which no ulcer was discoverable. From a further analysis of these 195 cases it appears that operative measures can rarely be relied on for the cure of active hematemesis, and that also in many cases operation was delayed until the conditions present were too serious to admit of recovery. When successful results are to be anticipated they are to be looked for in the category of cases with adhesions, cicatrices and stenosis chiefly, and in operations such as gastroenterostomy, performed between rather than during, attacks of hematemesis.

46. Blood in Pulmonary Tuberculosis.—Ullom and Craig examined the blood in 39 cases of pulmonary tuberculosis with the view of getting information with reference to the value of the blood findings in such cases from a prognostic standpoint. They found that in pulmonary tuberculosis, without cavity formation, a mild anemia, with a decrease in erythrocytes and a relatively greater decrease in hemoglobin, is constant. From the standpoint of prognosis, an increase of the erythrocytes, in cases without cavity formation, is of favorable significance. In advanced cases a decrease of the leucocytes is of unfavorable import. They received the impression that the actual increase of lymphocytes seems to correspond to the increase of resistance on the part of the organism to the tuberculous infection. The transitionals seem to follow the same rule as the lymphocytes in this regard. At the beginning of the investigation the eosinophiles seemed to increase with the patient's improvement, but further study did not support this view.

47. Rest in Laryngeal and Pulmonary Tuberculosis.—The great benefit derived from the non-use of the voice, says Porcher, is so striking that no one can fail to appreciate it who watches the progress of the case. It is not alone in cases of laryngeal tuberculosis that complete rest of the larynx and pharynx is indicated. In ordinary pulmonary cases efforts to phonate excite hypersecretion and contraction of the laryngeal muscles. Complete cessation of phonation, therefore, will lessen the amount of cough and consequent prostration, hyperpyrexia, etc. Rest, either partial or complete, should be paramount in all these cases.

49. Cyanosis Retinae.—Posey reviews the literature on this subject and cites a case seen by one of his assistants.

51. Causes of Gallstones.—The results of investigations made with the view of determining the causation of gallstones are detailed by Beer. He collected 12 cases at autopsy in which there had been common duct obstruction for more than four or five weeks and in which a more or less severe inflammation of the extrahepatic and intrahepatic ducts had developed. In 7 of these cases the common duct was obstructed by calculi, and in 5 by tumors of various kinds. In the first series of 7 cases, as a result of the conditions of the experiments, stones formed in the liver ducts. In the second series of 5 cases, though apparently the same conditions were present, no stones developed, though stagnation of bile and inflammation of the mucous membrane of the bile passages were present. Beer suggests that a faulty hepatic metabolism underlies the formation of gallstones. His investigations show that Naunyn's stagnation of bile, plus inflammation of the bile passage mucosa do not seem to be sufficient by themselves to lead to gallstone formation, even though the time allowed for the working of the causes be adequate. His first series of cases shows that these two factors lead to stone formation in patients who previously had gallstones.

54. Digestion in the Insane.—Cowie and Inch record the results of a series of investigations on the work of the digestive glands in the insane conducted at one of the Michigan asylums for the insane. Their conclusions are as follows: In states of mental depression (melancholia) hyperacidity is the rule, occurring in 71.4 per cent. of von Noorden's 14 cases, 81.8 per cent. of their 22 cases, or in 77.7 per cent. of all cases (3 in number). Males and females are equally affected. This hyperacidity is due to a true hyperchlorhydria. Hyper-total acidity also occurred in their cases, and in this respect they correspond exactly with those reported by von Noorden. The hyperchlorhydria is of moderate degree, is fairly constant, and is associated with increased power and rapid evacuation. The increased secretion is due to the neurosis or psychosis and not to proliferative changes in the glands, as is evidenced by the presence of increased secretion associated with degenerative changes in the glandular elements, and of the entire mucosa. The evacuation of the stomach is usually normal or somewhat hastened after the Ewald test breakfast, while after the large stimulus of the Riegel meal and the ordinary asylum meal it is more frequently hastened. In the cases showing hyperchlorhydria the peptic value is never below normal and is frequently increased. Many of the insane suffer from various forms of gastrointestinal disease. These conditions are very frequently overlooked, probably because complaints and delusions of the digestive tracts are so common in these patients. Experience and the results of this investigation prompt Cowie and Inch to urge the absolute necessity for systematic routine examination of all the secretions and functions of the body in these patients, including what is often a very difficult task, the examination of the stomach contents. The signs of disease in the insane are almost wholly objective, and here more than in normal mental states it is essential that every modern method of value should be exhausted in order to arrive at a complete diagnosis of the case. Cancer and ulcer of the stomach may thus often be recognized in its incipiency. Chronic gastritis in its several forms, as well as the painful neuroses, will also often be encountered. If proper treatment be instituted it is not at all improbable that the mental symptoms in these cases will proportionately decrease.

56. Relation Between Climate and Health.—Washburn discusses the relation between climatic conditions and health, with special reference to Americans in the Philippine Islands. He says that with respect to the principal climatologic factors, temperature, humidity and atmospheric movements, the climate of the Philippine archipelago is not extreme, as it is distinctly insular in character, the greater portion of the land area being not far distant from the ocean. There are other modifying influences which obtain in portions of the archipelago, such as general oceanic and local inter-island currents, prevailing winds, elevation, the state of cultivation and drainage of soil, and the presence of forests and other plant life. Excluding localities in the tropics characterized by excessive heat, high relative humidity or unhealthful soil conditions, acclimation or physiologic adaptation of the white man to tropical environment is possible. Failures of the white race to live in the tropics and to maintain health, excluding localities indicated in the second conclusion, appear to have been due principally to non-observance of the rules of personal, domestic and public hygiene. As a rule, Americans appear to become acclimated in the Philippines during the third year of residence. With sanitary surroundings, and by observing the rules of personal and domestic hygiene, residence of Americans in the Philippine Islands appears to be attended with as little danger of disease and death as residence in the United States under similar sanitary conditions.

57. Corneal Cyst.—Frank relates a case of corneal cyst in which there was no history of trauma or previous inflammation of the cornea. The patient had noticed the growth for fifteen years. It was situated at the apex of a pterygium, on the nasal side of the right cornea. The cyst measured 3 mm. in height, 4 mm. in width, by 5 mm. in length. It was opaque, whitish in color and firm to the touch. It contained about 2 mm. of a clear, almost colorless fluid, faintly alkaline in reaction. Microscopic examination of the cyst contents showed cellular débris and a few epithelial cells. The pterygium was torn loose from the cornea with a strabismus hook, destroying the anterior cyst wall at the same time. Forming the posterior surface of the cyst was a firm, thin scale of tissue, measuring 3 by 4 mm., which had probably separated from the cornea by pressure necrosis. This was dissected out and the wound in the conjunctiva was drawn together with two sutures and the corneal area corresponding to the cyst curetted. The wound healed promptly.

65. New Operation for Entropion and Trichiasis.—For the past ten years, Lagleyze has practiced exclusively in entropion, whether of the upper or lower lid, a method of his invention, which he has used in more than 300 cases without reproduction or injury to the normal aspect of the palpebral opening or to the lids. The operation does not require general anesthesia; local anesthesia is sufficient. He instills a few drops of cocain solution over the globe, and injects the same solution under the skin of the lid to be operated on; to the cocain solution he adds adrenalin chlorid. The necessary instruments are: a needle-holder, a bistoury, a pair of scissors to cut the threads of the sutures, which are to be of silk, and introduced by means of a number of curved needles about 3 cm. in length. For a complete entropion he employs six needles; for a partial entropion he uses a number in proportion to the extent of the entropion. After sterilizing the instruments, and making the region and field of operation aseptic, he proceeds to operate in the following manner: 1. The lid is everted in such a way that the limits of the superior border of the tarsal fibrocartilage are easily presented in the field of operation. 2. He inserts the needles into the conjunctiva, at the level of the tarsal superior border; slipping them between the fibrocartilage and the skin, so that they traverse the cellular tissue and orbicular muscle, and come out through the free palpebral border, at the level of the angle of implantation of the lashes. The needles should not be passed entirely through, but should be disposed so as to form a picture like that in Critchett's amputation. The needles should be spaced equidistant, it being advisable to commence by placing the first in the center, in order not to be preoccupied by maintaining the lid everted; then the others are inserted adjoining the center until the angles are reached. 3. He incises the conjunctiva and the tarsal cartilage parallel to the border of the lid, approximately 3 mm. from the free border, from one extreme to the other, if the entropion is complete. In partial entropion the incision must be made in proportion to the deformity, it being preferable, always, to extend the incision beyond the limits of the entropion. The incision is to be made with a bistoury, energetically, until obstructed by the needles, it being evident that a good result depends principally on a good division of the tarsus. 4. He passes all the needles and uses a traction on each of them, so that the deep loops of the thread are adapted to the surface of the conjunctiva. Immediately after the withdrawal of the needles, the lid returns to its former position. The ends of the threads which issue from the palpebral border must be separated so as to obtain five loops, if six needles have been employed. The ends corresponding to each loop should be strongly adjusted to a small roll of gauze. Making the knots in this manner the free border is not damaged, the sutures are not lost in the ulcerated tissues, and consequently there is no difficulty in withdrawing them. The advantage of this suture is due to the fact that the loops are successive without solution of continuity, thus obtaining a number of loops equal to the number of needles employed, less one. The sutures are to be withdrawn in seven or eight days. The palpebral border, from the point of incision, takes a contrary direction; it is directed forward to such a point that if it is desired to exaggerate the effect, it may provoke a slight ectropion. The angle left by the incision forms a wedge which cicatrizes by second intention, filling the tissues with a new growth, and the length of the threads which maintain the corrective incurvation produces cicatricial lines which assist in the definite cure of the entropion.

15 New Test for Visual Acuteness. G. A. Berry.

2. **Rats and Plague.**—Skinner discusses the question of whether rats are really the transmitters of plague to man or whether some other animal is responsible for the conveyance of disease. He inclines to the latter view.

4. **Intraocular Tuberculosis.**—Jessop has never seen a case he could prove to be primary intraocular tuberculosis, and doubts the existence of such a condition. He says that excision in intraorbital tuberculous conditions of the eye should seldom be done, unless there is much pain or the condition is telling on the patient's health, because the disease is not primary, and such a procedure would only remove one focus of the disease. He has never seen vitreous opacities in miliary tubercle of the choroid; neither were they present in two cases of chronic choroidal tubercle seen by him. He has had little experience with tuberculin, either as a diagnostic or as a therapeutic agent.

5. **Id.**—Hess employed old tuberculin in eighteen cases and Tr. in eight cases for diagnostic purposes. In thirteen cases there was a general reaction and in two cases a local reaction. Among the cases of iritis, a general reaction was present in more than 50 per cent. It was also present once in

a case of recent choroiditis, and once in a case of keratitis parenchymatosa. He has never observed any ill effect from tuberculin employed therapeutically. In one case of iritis there was an evident improvement after its use.

6. **Id.**—Hern has employed the new tuberculin for diagnostic purposes in many cases. In at least 85 per cent. of the cases there was a general reaction, and in about 50 per cent. there was some local reaction. He considers tuberculin useful as a diagnostic agent, but useless in treatment. He believes that in some cases it was harmful by setting up inflammatory changes in the eye.

9. **False Hay-Fever.**—Harman calls attention to an infection that simulates true hay-fever, but which is caused by eye-strain. Several such cases of astigmatism were relieved of the hay-fever symptoms by the wearing of proper glasses.

14. **Blepharoplasty.**—Benson describes what he terms the St. Mark's Hospital operation as follows: The patient being anesthetized, and a Snellen's or a Knapp's clamp having been applied to the lid, an incision is made with a Graefian knife along the whole length of the free border of the lid in such a way that all the cilia are contained in the anterior or skin flap, and no cilia in the posterior or conjunctival flap. The incision is made at least one-quarter of an inch in depth and rather obliquely forward, so that it allows the wound to gape freely. In case any errant hair bulbs have been left in the posterior segment, these can be easily dissected out. A second clamp is now applied to the patient's lip, and two parallel incisions are made with the Graefian knife through the mucous membrane. The length of these incisions is rather shorter than the incisions in the lid. The ends of these parallel incisions are now connected by short converging incisions so as to make the flap pointed at each end. This flap is then dissected up with a scissors and forceps. It is placed on the finger of the left hand, and all submucous fat and connective tissue is cut off with a scissors. A silk suture attached to a fine curved needle is then passed through one end of the flap and it is sutured into one end of the gaping incision made in the lid. The other end is similarly sutured, and each edge is fixed by two or more sutures to the corresponding edges of the lid incision. The clamp is then removed. Profuse bleeding follows for a few minutes, but soon stops. A dressing of boric ointment is applied to the eyelid and a simple form of a bandage is applied. The sutures may be removed after four or five days. A knot on the silk suture used to fix the extremities of the flap considerably aids its accurate adaptation. The operation is equally suitable to the upper and the lower lids and to all varieties of trichiasis, with or without entropion. The result of the operation is permanent.

18. **Aciduria as Cause of Death After Anesthesia.**—Guthrie is of the opinion that the symptoms preceding death in these cases suggest acid intoxication by the poisonous precursors of acetone, and that these bodies take their origin in the disintegration of fat. In practically all cases of death following the administration of anesthetics, advanced fatty metamorphosis is found in most organs, notably in the liver. Ether is not capable of producing similar changes, yet they are found apparently to the same extent in deaths following ether as in deaths after chloroform. It therefore follows that such fatty metamorphosis must have existed prior to the anesthetization. The disintegration of fat into acid poisons may be due to the direct action of chloroform and ether in altering normal metabolism, or in some way they may favor the action of bacterial toxins present in the intestines in causing disintegration of fat. In any case, says Guthrie, the pre-existence of advanced fatty changes must be presumed in order to explain fatty acid intoxication, although it is probable that the fatty changes in the liver are physiologic and of the nature of infiltration rather than of degeneration. If this be so, it is possible to understand why anesthetics are dangerous at one time and not at another, the element of danger being the superabundance of fat existing in the liver at the time of operation. The storage of superfluous fat in the liver in some case may be due to the large quantities of cod-liver oil and fattening diet commonly supplied to delicate, crippled and rickety children in the hope of strengthening them, coupled with want of exercise. In accordance with the foregoing views, Guthrie advances the following conclusions for the prevention of untimely deaths of children after operations: 1. Before operation on even fat and apparently healthy children a careful inquiry should be made as to history of. so-called "bilious attacks," which may in reality be those of "acidosis." 2. In all cases in which overfattening and want of exercise are suspected, operation should be delayed, if possible, until the patient has for some days been subjected to fat-free diet. Mild purgation during this period is probably indicated. The urine should be examined for diacetic acid and, if present, a course of alkalies, such as bicarbonate of sodium, should be prescribed. 3. It should be remembered that both starvation and fright give rise to acetonuria. The four hours' fast usually imposed on children before operation is too long, especially when one considers that it will necessarily continue not only during the operation, but for many subsequent hours. Nutrient enemata should be given, after clearing the lower bowel, two hours before an operation and immediately afterward. The effect of fright can not be altogether controlled, but may be combated by preventing starvation. 4. The treatment of symptoms of acid intoxication following operations should be by venesection, saline transfusion, and by clysters of solution of bicarbonate of sodium.

21. **Syphilis of Third Generation.**—Marshall cites a case of this kind. The grandmother of the patient had the scars of multiple gummata about both knees. The mother, at the age of 16, had a gumma of the popliteal space and extensive destruction of the palate leading to constriction of the nasopharynx. She married at the age of 19 years and had three children, but no miscarriages. The first child (the one under consideration), had a distinct saddle-nose deformity and frontal bosses, but no other dystrophic stigma of hereditary syphilis. The second child died at the age of 3 years from bronchitis; the third child is said to be healthy. The possible flaws in the evidence are: 1, Acquired syphilis in the mother; 2, reinfection of the hereditary syphilitic mother; 3, acquired syphilis in the father, and 4, the intervention of another syphilitic genitor. In the absence of obvious signs of hereditary syphilis in the mother, says Marshall, it is absolutely impossible to exclude acquired syphilis, but extensive or advanced tertiary syphilis at the age of 16 years is strongly in favor of the hereditary disease. Syphilis of the father can not be excluded, as he was not examined. In view of the fact, however, that all three generations were under observation for some years, Marshall is of the opinion that the case can be regarded as one of probable transmission of syphilis to the third generation. He concludes his paper as follows: 1. The degenerative or dystrophic effects of syphilis are transmissible to the third generation and possibly further, only to die out with eventual sterility. 2. Although difficult to prove, the transmission of the virulent hereditary syphilis to the next generation is scientifically possible; the question depending chiefly on the two factors of time and treatment. We know that the signs of late hereditary syphilis may be delayed till the procreative age; hence a hereditarily syphilitic genitor in a virulent state might transmit the disease in virulent form to the offspring. The reason why such cases are rare is the fact that a small proportion of patients marry while suffering from hereditary syphilis in a virulent form. At the time of marriage the disease is usually attenuated by time and also by treatment if this has been adequately administered. 3.

Reinfection of a hereditarily syphilitic genitor increases the virulence of the disease and its fatal effects on the offspring (binary syphilis of Tarnowsky). 4. The two chief obstacles to actual proof of transmission to the third generation are the possible reinfection of the second generation and the possible intervention of another syphilitic genitor.

22. **Ruptured Interstitial Pregnancy.**—Nash's case is an example of interstitial pregnancy, the rarest form of extrauterine gestation. During the fourth month (fifteenth week), rupture occurred, and in spite of operation the patient succumbed. Apparently the ovum became delayed in the left Fallopian tube where it passes through the uterine wall, and as it developed caused hypertrophy of the uterine tissues above the entrance of the tube. The uterine tissue was thinnest on the abdominal aspect of the gestation sac, so that when rupture took place it occurred into the peritoneal cavity. There was no separation of the uterine decidua, which accounted for the absence of vaginal hemorrhage or any other sign suggestive of an ordinary miscarriage.

24. **Quinin in Blackwater Fever.**—Mowbray reports a case of blackwater fever occurring in the northern part of Ireland, the patient having been infected a year or more previously in Africa. Quinin was given hypodermically in an initial dose of 18 grains, followed by 10 grains three times daily for five days, and then twice daily for two days more. The patient improved rapidly, but on the discontinuance of the remedy suffered an alarming relapse. A renewal of the quinin again brought about abatement to the symptoms, and the patient recovered.

26. **Onward March of Cholera in 1904.**—This article was summarized in the news columns on page 336.

27. **Hereditary Transmission of Stigmata of Degeneration in Royal Families.**—Galippe remarks that a scientist who should forcibly apply the rules of puericulture to the production of teratologic monstrosities would be blamed, but that which is denied to the experimenter has been realized in certain reigning families of Europe. Instead of sexual selection, marriage has been regulated by pride of caste or political necessities, and the resulting intermarriages have perpetuated certain stigmata which can be readily traced through generations by portraits and historical records. In the Hapsburg family of Austria, for instance, the inferior prognathism and exaggerated development of the lower lip can be traced in the portraits through generations. When an anomaly of this kind occurs it is generally accompanied by other anomalies, obvious or internal. In the Hapsburg family the portraits from the middle of the fifteenth century to our day show a lateral flattening of the skull, causing the forehead to be unusually high, the eyes more or less protruding and the lower jaw and nose varying from normal. Even when the female members of the family did not present these stigmata they conferred them on their offspring. Napoleon's son by the Austrian princess had all the characteristics of the Hapsburgs, not of Napoleon. The claim of Naundorff to be the missing son of Louis XVI and Marie Antoinette was disproved by the absence of the Hapsburg stigmata which he would certainly have inherited, as both father and mother were of the Hapsburg stock. Galippe regards inferior prognathism, that is, the lack of correspondence between the upper and lower jaw and the protrusion of the latter, as a sign of marked degeneracy. It has been developed in the bulldog, and this breed of animals is developing other stigmata of degeneracy. In animals it is usually accompanied by a twisting and shortening of the legs, as in the crocodile. In man it is frequently accompanied by many of the signs of acromegaly. He gives a number of illustrations of members of the Hapsburg family, all showing the projecting lower jaw and long, narrow face, the frequent coincidence of adenoid vegetations being an added anomaly. This adenoid type is reproduced again and again in the reigning families so that many of the portraits are actually superposable. Acromegaly is at the top of the scale in which inferior prognathism is at the bottom, but the similarity between them in many respects suggests new fields for research in regard to the transmission of stigmata of degeneracy.

28. **Tuberculous Fibrolipoma of the Knee.**—Couteaud's patient recovered normal use of the joint after extirpation of the growth, which weighed 14 gm. Its tuberculous nature was demonstrated by the microscope and by inoculation of guinea-pigs.

29. **Influence of Intercurrent Diseases on Course of Palate Operations.**—Ehrmann reports three cases in which intercurrent scarlet fever in two and diphtheria in the third did not interfere with the success of the suture. Others have reported serious disturbances from an intercurrent affection. In his patients the first symptoms did not appear until three days or more after the operation and the suture escaped infection in all. He ascribes this fine result partially to his technic of operating in two sittings. His experience now comprises 65 cases in which he operated in this way. By reducing hemorrhage and shock, the child's receptivity is diminished and it is able to resist bacterial invasion better.

30. **Complete Anesthesia by the Subcutaneous and Stomach Routes.**—Gréhant injected 1 cg. of morphin per kilogram in a dog weighing about fifteen pounds, and in half an hour he poured into its stomach 350 c.c. of 10 per cent. alcohol containing 1.75 c.c. of chloroform. The resulting anesthesia in fifteen minutes was more complete and the dog was more tranquil than he has ever observed in all his experience with experimental anesthesia. In further tests with the same technic on a larger dog he noticed that the rectal temperature dropped several degrees and that the amount of carbonic acid gas exhaled by the lungs was much less than before, which explains the lowering of the temperature. Chloroform dissolves readily in 10 per cent. alcohol; a liter takes up 5 c.c. of chloroform, and this is the solution which he uses. He recommends this technic for man in case of extensive burns and crushing accidents. By injecting a small amount of morphin and giving a little chloroform in diluted alcohol it may prove possible to arrest all the pain without injury to the patient.

31.—See 27 above.

32. **Clinical Examination of Respiratory Interchanges.**—Hitherto investigation of the respiratory interchanges has been confined to the laboratory, but Robin has now invented an apparatus which allows it at the bedside. He gives a number of illustrations of the various parts of the apparatus. It registers the number of inspirations per minute, the volume of maximum expiration or the vital capacity, the pulmonary ventilation or volume of air expired per minute, the amount of carbonic acid and of the various gases produced, combined or absorbed, and the relations between these various factors of the respiratory functions. He has been conducting research with this apparatus on patients with typhoid fever, pleurisy, ascites, diabetes, osteomalacia, dyspepsia, cancer, hemorrhage, tuberculosis and the rheumatic diathesis. Study of the respiratory interchanges further throws light on the effects of drugs and of hydrotherapy and climatotherapy. In typhoid fever the respiratory interchanges are in inverse proportion to the severity of the disease. These findings justify the use of drugs which increase the consumption of oxygen and favor oxidations, and they contraindicate drugs with opposite effects.

a case of recent choroiditis, and once in a case of keratitis parenchymatosa. He has never observed any ill effect from tuberculin employed therapeutically. In one case of iritis there was an evident improvement after its use.

6. **Id.**—Hern has employed the new tuberculin for diagnostic purposes in many cases. In at least 85 per cent. of the cases there was a general reaction, and in about 50 per cent. there was some local reaction. He considers tuberculin useful as a diagnostic agent, but useless in treatment. He believes that in some cases it was harmful by setting up inflammatory changes in the eye.

9. **False Hay-Fever.**—Harman calls attention to an infection that simulates true hay-fever, but which is caused by eye-strain. Several such cases of astigmatism were relieved of the hay-fever symptoms by the wearing of proper glasses.

14. **Blepharoplasty.**—Benson describes what he terms the St. Mark's Hospital operation as follows: The patient being anesthetized, and a Snellen's or a Knapp's clamp having been applied to the lid, an incision is made with a Graefian knife along the whole length of the free border of the lid in such a way that all the cilia are contained in the anterior or skin flap, and no cilia in the posterior or conjunctival flap. The incision is made at least one-quarter of an inch in depth and rather obliquely forward, so that it allows the wound to gape freely. In case any errant hair bulbs have been left in the posterior segment, these can be easily dissected out. A second clamp is now applied to the patient's lip, and two parallel incisions are made with the Graefian knife through the mucous membrane. The length of these incisions is rather shorter than the incisions in the lid. The ends of these parallel incisions are now connected by short converging incisions so as to make the flap pointed at each end. This flap is then dissected up with a scissors and forceps. It is placed on the finger of the left hand, and all submucous fat and connective tissue is cut off with a scissors. A silk suture attached to a fine curved needle is then passed through one end of the flap and it is sutured into one end of the gaping incision made in the lid. The other end is similarly sutured, and each edge is fixed by two or more sutures to the corresponding edges of the lid incision. The clamp is then removed. Profuse bleeding follows for a few minutes, but soon stops. A dressing of boric ointment is applied to the eyelid and a simple form of a bandage is applied. The sutures may be removed after four or five days. A knot on the silk suture used to fix the extremities of the flap considerably aids its accurate adaptation. The operation is equally suitable to the upper and the lower lids and to all varieties of trichiasis, with or without entropion. The result of the operation is permanent.

26. **Onward March of Cholera in 1904.**—This article was summarized in the news columns on page 836.

27. **Hereditary Transmission of Stigmata of Degeneration in Royal Families.**—Galippe remarks that a scientist who should forcibly apply the rules of puericulture to the production of teratologic monstrosities would be blamed, but that which is denied to the experimenter has been realized in certain reigning families of Europe. Instead of sexual selection, marriage has been regulated by pride of caste or political necessities, and the resulting intermarriages have perpetuated certain stigmata which can be readily traced through generations by portraits and historical records. In the Hapsburg family of Austria, for instance, the inferior prognathism and exaggerated development of the lower lip can be traced in the portraits through generations. When an anomaly of this kind occurs it is generally accompanied by other anomalies, obvious or internal. In the Hapsburg family the portraits from the middle of the fifteenth century to our day show a lateral flattening of the skull, causing the forehead to be unusually high, the eyes more or less protruding and the lower jaw and nose varying from normal. Even when the female members of the family did not present these stigmata they conferred them on their offspring. Napoleon's son by the Austrian princess had all the characteristics of the Hapsburgs, not of Napoleon. The claim of Naundorff to be the missing son of Louis XVI and Marie Antoinette was disproved by the absence of the Hapsburg stigmata which he would certainly have inherited, as both father and mother were of the Hapsburg stock. Galippe regards inferior prognathism, that is, the lack of correspondence between the upper and lower jaw and the protrusion of the latter, as a sign of marked degeneracy. It has been developed in the bulldog, and this breed of animals is developing other stigmata of degeneracy. In animals it is usually accompanied by a twisting and shortening of the legs, as in the crocodile. In man it is frequently accompanied by many of the signs of acromegaly. He gives a number of illustrations of members of the Hapsburg family, all showing the projecting lower jaw and long, narrow face, the frequent coincidence of adenoid vegetations being an added anomaly. This adenoid type is reproduced again and again in the reigning families so that many of the portraits are actually superposable. Acromegaly is at the top of the scale in which inferior prognathism is at the bottom, but the similarity between them in many respects suggests new fields for research in regard to the transmission of stigmata of degeneracy.

28. **Tuberculous Fibrolipoma of the Knee.**—Couteaud's patient recovered normal use of the joint after extirpation of the growth, which weighed 14 gm. Its tuberculous nature was demonstrated by the microscope and by inoculation of guinea-pigs.

29. **Influence of Intercurrent Diseases on Course of Palate Operations.**—Ehrmann reports three cases in which intercurrent scarlet fever in two and diphtheria in the third did not interfere with the success of the suture. Others have reported serious disturbances from an intercurrent affection. In his patients the first symptoms did not appear until three days or more after the operation and the suture escaped infection in all. He ascribes this fine result partially to his technic of operating in two sittings. His experience now comprises 65 cases in which he operated in this way. By reducing hemorrhage and shock, the child's receptivity is diminished and it is able to resist bacterial invasion better.

30. **Complete Anesthesia by the Subcutaneous and Stomach Routes.**—Gréhant injected 1 cg. of morphin per kilogram in a dog weighing about fifteen pounds, and in half an hour he poured into its stomach 350 c.c. of 10 per cent. alcohol containing 1.75 c.c. of chloroform. The resulting anesthesia in fifteen minutes was more complete and the dog was more tranquil than he has ever observed in all his experience with experimental anesthesia. In further tests with the same technic on a larger dog he noticed that the rectal temperature dropped several degrees and that the amount of carbonic acid gas exhaled by the lungs was much less than before, which explains the lowering of the temperature. Chloroform dissolves readily in 10 per cent. alcohol; a liter takes up 5 c.c. of chloroform, and this is the solution which he uses. He recommends this technic for man in case of extensive burns and crushing accidents. By injecting a small amount of morphin and giving a little chloroform in diluted alcohol it may prove possible to arrest all the pain without injury to the patient.

31.—See 27 above.

32. **Clinical Examination of Respiratory Interchanges.**—Hitherto investigation of the respiratory interchanges has been confined to the laboratory, but Robin has now invented an apparatus which allows it at the bedside. He gives a number of illustrations of the various parts of the apparatus. It registers the number of inspirations per minute, the volume of maximum expiration or the vital capacity, the pulmonary ventilation or volume of air expired per minute, the amount of carbonic acid and of the various gases produced, combined or absorbed, and the relations between these various factors of the respiratory functions. He has been conducting research with this apparatus on patients with typhoid fever, pleurisy, ascites, diabetes, osteomalacia, dyspepsia, cancer, hemorrhage, tuberculosis and the rheumatic diathesis. Study of the respiratory interchanges further throws light on the effects of drugs and of hydrotherapy and climatotherapy. In typhoid fever the respiratory interchanges are in inverse proportion to the severity of the disease. These findings justify the use of drugs which increase the consumption of oxygen and fa oxidations, and they contraindicate drugs with opposite ef

In cases of ascites the respiratory changes are increased, paralleling the amount of ascites. The liver and the lungs have a common function, the elimination of carbon. When one becomes unequal to the task the other vicariously takes it up. After puncture, which relieves the ascites and hence the liver, the latter organ is able to reassume some of this task, and the interchanges in the lungs subside to a lower figure. This conjugate vicarious action of liver and lungs suggests, he thinks, that it might be possible to stimulate the liver functions to increased vicarious action when the lungs are unable to eliminate all the carbon necessary, or *vice versa* to stimulate the lungs to vicarious action when the liver is proving insufficient. Another important point in this connection is that the respiratory chemistry may serve to determine the best moment for tapping ascites. In diabetes the respiratory changes are more intense than in normal conditions. Consequently it can not be considered a disease due to retarded nutrition, but rather the reverse. It requires sedative medication and not measures to stimulate the various chemical activities of the organism. Sedative treatment reduces the respiratory changes as well as the glycosuria. This increased intensity of the respiratory interchanges explains why diabetics are peculiarly exposed to tuberculosis as it prepares the soil for the latter disease. If the respiratory changes remain high in a diabetic, even if the sugar has vanished from the urine, he is not cured and is always in danger of recurrence of the glycosuria. When the respiratory changes drop, especially when not accompanied by a corresponding drop in the sugar in the urine, coma is imminent and measures should be instituted to restore the respiratory functions nearer to normal. Hemorrhage has the effect of increasing the respiratory changes, showing that abstraction of a moderate amount of blood promotes general oxidation. Venesection is, therefore, indicated in affections with retarded nutrition from insufficiency of the nutritive processes, and also in autointoxications and in certain infectious diseases, like pneumonia, when the microbian poisons or those elaborated by the organism in its struggle against the infectious agent or poison, are causing serious damage. Withdrawal of blood accelerates the oxidations and thus aids in neutralizing these poisons, transforming them into soluble non-toxic products, easily eliminated. He has found that the respiratory changes are notably increased in 92 per cent. of all cases of tuberculosis, and during all stages of the disease. This increase in the respiratory changes is one of the manifestations of the "tuberculisable soil," as he calls it. The exaggerated aptitude to consume too much oxygen and to elaborate too much carbonic acid, that is, to consume itself, is the characteristic of the organism predisposed to consumption. The pretuberculous condition is one of exaggerated vitality, not, as generally supposed, one of depressed vitality. This view upsets all our preconceived notions in regard to prevention and treatment of tuberculosis. Instead of tonics we need measures to restrain the organism from burning itself up, and study of the respiratory interchanges reveals the measures suitable for this purpose and the exact doses that produce the finest results. The predisposed should be sorted out and treated the same as we vaccinate, by modifying the vital conditions of the soil. This respiratory syndrome is trasmitted to 60 per cent. of the descendants of tuberculous parents. In the rheumatic diathesis, the respiratory changes are diminished and the type is the reverse of that observed in tuberculosis. It is transmitted to 72 per cent. of the descendants as a rule. Oxygen supplied to the organism in excess does not materially modify the respiratory changes; they seem to depend more on the aptitude of the tissues to fix the oxygen than on the amount supplied.

36. **Pylorectomy for Cancer.**—Poncet has performed pylorectomy with more or less extensive excision of the stomach in 12 cases of cancer and 8 of the patients recovered. The cachexia or extension of the lesion or imperfect technic explain the fatalities. The remote conditions are eminently satisfactory in the patients cured, and justify his advocacy of immediate exploratory laparotomy on suspicion of cancer of the stomach, with more or less extensive gastrectomy as found necessary. Gastrectomy, he states, is not a serious operation when the lesion is in an early stage. The prospects were far from favorable in some of his cases.

37. **Connection Between Albuminuria and Diabetes.**—Lancereaux has observed albuminuria frequently in his cases of gouty, herpetic diabetes, while it was never noted in his 40 cases of pancreatic diabetes. The glycosuria alone does not entail albuminuria. When the latter occurs it may be connected with arteriosclerosis with consequent lesions of kidneys and heart, or it may be of epithelial origin due to some intercurrent affection, tuberculosis in particular. There is a third form, in which the albuminuria alternates with the glycosuria, and like the latter, is subordinate to some nervous disorder. He gives examples of each form, and adds that the physician should examine the condition of the kidneys and nervous system in such a patient, rather than determine the exact proportion of albumin. This will give him a clue both for treatment and for prognosis. There are three groups of circumstances in which this decision is of great value: When parents bring their sons to the consultant with the statement that their physician has told them that the lads are albuminuric and must be put on a milk diet, and that they must stop their college work. Study of the albuminuria and its accompaniments reveal that it is not due to a kidney lesion, and consequently that these precautions are unnecessary. Time shows that the lads develop spontaneously into good health and their albuminuria vanishes. In other cases life insurance is refused to men apparently in good health, under pretext of albuminuria. The kidneys are sound and the insurance company may be prevailed on to reconsider its objections.

39. **Bactericidal Properties of Typhoid Immune Serum.**—The various experiences reported elucidate some of the problems and antagonistic findings of others in the line of bacteriolysis, immunization, etc.

41. **Pathogenesis, Symptomatology and Diagnosis of Deformities in the Ureters in Women.**—Thumin's long article is based on the literature and on experience, especially on a case personally observed in which a supernumerary ureter presented a large cystic enlargement. The supernumerary ureter was located behind the peritoneum, and terminated in a cul-de-sac in the connective tissue. The symptoms of trouble in a ureter were puzzling, as both of the normal ureters could be seen functioning perfectly. Removal of the tumor restored condition to normal in every respect. The symptoms of ureter anomalies are generally disturbances in urination, especially incontinence while the bladder is continent. This occurs only when a persisting Gartner's duct opens into the roof of the vagina. The differentiation is extremely difficult when the ureter terminates in a blind sac. In the case described the nature of the cyst was revealed only by microscopic examination of the walls. The character of the superficial epithelium of the mucous membrane lining the cyst testified to its connection with the urinary apparatus.

42. **Recent Progress in Diagnosis of Tuberculosis.**—De la Camp discusses the value of the more recent diagnostic points in tuberculosis, saying that, on the whole, the old, classical

diagnostic measures are still superior to anything offered in recent years. His experience has been that bacilli can not be detected in even a third of all cases with expectoration. Abnormal auscultation findings are generally associated with abnormal percussion findings. Signs of irritation of the sympathetic, such as differences in the pupils, are important, as also suspicious Roentgen findings, especially in respect to tumefied glands in the mediastinum. About a third of all cases of localized apical tuberculosis present Williams' sign, that is, reduced movability of the affected half of the diaphragm. The anamnesis is of the greatest diagnostic importance, particularly a history of disturbances in the nervous system. The temperature may reveal its pathologic character only when examined directly after physical exercise.

43. **Affections That Precede Carcinoma.**—Bergmann calls attention to the frequency of certain affections in the preceding history of cancer subjects. Among them he cites severe congenital phimosis as a frequent antecedent of large carcinoma of the penis, also large scars resulting from burns. He has personally observed a striking case of this latter combination. A child of 4 fell into an open fire and was burned so that the resulting cicatricial contraction drew the skin of the axilla down to the hip. At the age of 40 a carcinoma developed on the cicatricial tissue, forming the largest cancer which he has ever had occasion to see. He has found a history of Paget's disease of the nipple in only 7 or 8 cases among his 1,000 operative cases of mammary cancer. The carcinoma develops directly from the eczematous alterations in this affection, as also in the acne of workers in paraffin. The latter exhibit usually multiple primary carcinomata. Psoriasis of the tongue and mouth may also be the precursor of a carcinoma. He does not credit a syphilitic etiology to this affection, as the lesion is not at all like those of the tertiary type of syphilis. In a case demonstrated he removed a carcinoma located in the middle of the patches and there has been no recurrence to date after two and a quarter years. He has also observed carcinoma developing on a lupus cicatrix and also from a fibroid lupus lesion. Lesser has reported cases of carcinoma in children of from 12 to 15 years which developed on the basis of xeroderma pigmentosum and was rapidly fatal. Bergmann denies the existence of primary carcinoma on the extremities without a preceding cutaneous lesion, scar, fistula opening, ulcer, eczema, wart or mole. A pigmented nevus leads more often to the production of a melanotic sarcoma than of a carcinoma. The smooth, small, multiple pigmented nevi contain nerve terminals from which minute fibromata are liable to develop, leading possibly to elephantiasis neuromatosa. The warty, dark-colored nevi are liable to be the seat of melanotic carcinoma, as in a case he reports. A small, dark-colored, hairy, raised nevus on the head showed little change for thirty-seven years after birth. Then the nevus began to grow, a bunch developed behind the ear and the enlarged glands of the region can be seen like a string of beads under the skin down to the back of the neck.

45. **Laparotomy and Drainage for Puerperal Peritonitis.**—Kownatzki states that 9 cases of non-encapsulated puerperal peritonitis have been treated at Bumm's clinic at Berlin. Two of the patients were moribund when seen, 2 others were operated on, but succumbed later. In one of the fatal cases pus had already found its way into the pleural cavity. In the other the affection proved to be a number of imperfectly encapsulated single abscesses which it would have been impossible to drain effectually and the development of which had evidently been favored by the opium previously given. It is possible that both these patients might have been saved if operated on sooner. All the other patients were cured by laparotomy and drainage with counter openings. He gives the details of these cases. In 2 there was septic infection; streptococci were numerous in the peritoneal exudate. He knows of no other instance on record of the cure of similar puerperal streptococcus, non-encapsulated peritonitis. The abscess contents were putrid in the 3 other cases. The peritonitis developed very slowly in all, the clinical picture not becoming complete until the seventh to the tenth day after delivery. The general health also was only very gradually impaired and the abdomen was only slightly sensitive to pressure. The difficulty of diagnosing the condition is so great in a woman convalescing from childbirth, that exploratory puncture is justifiable and urgent in dubious cases. The abdomen can be punctured with a small Pravaz needle without fear. Certainty was attained by this means alone in three of his cases. In another a small exploratory incision at the most suspicious point cleared up the diagnosis. A thorough operation is inadvisable, and the main idea is merely to secure the best possible conditions for rubber tube drainage. The incision was made in the inguinal region at the point where inflammatory processes originating in the uterus usually first reach the abdominal wall. The counter-incision was made at the lowest part of the lumbar region, where it merges into the back. There was no swabbing or rinsing, but the parts were thoroughly drained, secretions draining away for several days, as the symptoms subsided.

46. **A New Action of the Cell Nucleus-Phagokaryosis.**—Detre and Sellei found that it is possible to protect animals effectually against sublimate injections by mere subcutaneous injection of an aqueous or serous emulsion of lecithin. In ordinary phagocytosis the cell nucleus takes no part in the process, but with this emulsion of lecithin the nucleus incorporates the grains of the lecithin. It is evidently an active, independent process on the part of the nucleus which seems to have an affinity for the lecithin grains and to absorb them with avidity. They propose the term phagokaryosis for this action on the part of the cell nuclei.

48. **Laryngeal Tuberculosis and Pregnancy.**—Kuttner discusses the question as to interruption of a pregnancy in case of laryngeal tuberculosis. His conclusions are the result of ripe deliberation and council with lawyers as well as with physicians. He first reiterates the statement that diffuse laryngeal tuberculosis during pregnancy has an extremely unfavorable prognosis. The death rate of children whose mothers suffered from laryngeal tuberculosis during the pregnancy is exceptionally high. These facts theoretically justify artificial interruption of the pregnancy, but in practice the measure is permissible only when the conditions indicate that it is the only chance to save the life of the mother and offers some probability of success. Experiences to date have demonstrated that premature delivery in the last months of the pregnancy has little prospect of a favorable outcome. In this stage tracheotomy might still offer some chances.

49. **Blood Serum Reaction of Cancer Subjects.**—Kelling found in certain cases of carcinoma some special precipitins in the serum which displayed characteristic relations to a foreign albumin. He was unable to detect this reaction in case of other affections, and proclaims that its occurrence under reliable technic is a sure sign of some hidden carcinoma, but the absence of the reaction is no evidence that cancer does not exist somewhere. Fuld criticizes his assertions, and states that his control experiments were always negative and that Kelling's communication is not scientifically exact or complete.

52. **Disinfection of the Skin.**—Vogel has been using the apparatus for applying superheated air in his experiments in regard to disinfection of the hands. The impetus to the circulation and perspiration in the hot-air bath is a good means to test the depth of the action of the disinfectants. He held his disinfected hand in the hot-air box, and from the number of germs found on it afterward drew conclusions as to the more or less completeness of the preceding disinfection. The germs thus brought to the surface could easily be destroyed. He is convinced that the germs found after this exposure proceed less from the crevices in the skin than from the gland passages. If the surgeon's hand becomes soiled the best way to free it from germs is to hold it in the hot-air box, and thus sweat out all impurities from it. This method of disinfection might also be applied to parts of the body covered with hair, supplementing the physical, mechanical and chemical procedures by this physiologic enhancing of the natural activity of the skin. He suggests that stitch hole suppurations might be avoided by always taking the stitch from within outward, never from without inward, and by always taking a fresh needle for every stitch. His tests of various technics for disinfection showed that the Fürbringer hot water-alcohol-sublimate method is superior to Mikulicz' tincture of soap method in regard to the sterility of the hands, but the latter technic has so many advantages and the results are so good that he still clings to it in preference to the other.

53. **Post-traumatic Psychoses.**—Weber gives a number of examples from his own experience, remarking that there is no *uniform clinical picture for the traumatic psychoses.* A connection may be assumed between the accident and the psychosis when the character changes immediately or soon after the accident, becoming irritable or slightly depressed. Also when an organic brain affection, especially a fulminating paralysis, sets in soon after the trauma. In a functional psychosis an association with the trauma may be surmised when there is depression and anguish, associative and motor inhibitions or catatonic disturbances, in addition to the ordinary characteristic symptoms of the psychosis. To assume a connection with the trauma, the psychosis must have developed soon afterward and have been preceded by a prodromal period of altered psychic behavior.

54. **Breathing Therapy for Heart Affections.**—Herz believes that great benefit can be derived from endo-massage of the heart by expelling the air from the lungs in a series of jerks. This "staccato breathing," as Oertel called it, causes transient increase in the pressure in the thorax and thus acts indirectly on the heart from all around it, not from any one point alone. The participation of the abdominal muscles is superfluous, and for this and other reasons he has invented a little instrument which mechanically produces and controls the staccato expiration. The patient breathes into a tube connected with a wheel and ratchet below, which alternately open and close the outlet to the tube.

56. **Ship Sanatoria.**—Leyden outlines the desiderata for a floating sanatorium, and advocates sea voyages or a sea life in prevention and cure of scrofula, tuberculosis, etc. He advised eighteen lads from very consumptive families to enter the marine service, and only two out of the entire number have ever shown signs of tuberculosis, while their brothers and sisters, who preferred a sedentary life, have paid a very large contingent to the disease.

57. **Epidemic Cerebrospinal Meningitis.**—In this third installment of his official report Lingelsheim states that he succeeded in reproducing the clinical picture of epidemic meningitis in a monkey by instraspinal inoculation of human material.

59. **Injuries from Amniotic Constriction.**—Illustrations are given of two girls, each born with a groove around the arm or leg and paralysis or clubfoot. In one case the peripheral nerves had evidently suffered from the amniotic constriction of the arm just above the elbow, as the child exhibited radial paralysis and there was also partial ulnar paralysis. The cases throw light on the origin of certain cases of clubfoot and of paralysis of isolated peripheral nerves.

60. **Determination of Sensibility of Muscles and Joints.**—Curschmann describes his galvano-muscular technic with which he has been able to detect a reduction in the sensibility in incipient tabes when the findings by all other technics were negative. He determines the minimal "threshold value" of the sensibility, and then requests the patient to note whether a movement of the muscle accompanies the sting when the current is turned on. The patient is almost always able to differentiate the peculiar, brief sensation of movement in the muscles under electric stimulation, and the effect of the movement on the neighboring parts, and also to point out the course of the muscle involved. By this means it is easy to learn the strength of current necessary to induce the sensation of the contraction of the muscle. He gives tables of the findings on normal and diseased subjects and reviews the information to be derived from comparison of them.

61. **New Immunizing Means of Curing Tuberculosis: Bovine Tuberculin.**—Spengler's first announcement in regard to the value of immunization by means of bovine tuberculin was summarized in these columns on page 705 of vol. xliii. He here describes further experiences with his perlsucht tuberculin, its agglutinating properties, an attempt at autoinfection and a differential stain for the bovine tubercle bacillus. The serum of persons under treatment with persulcht tuberculin acquires remarkable agglutinating properties without a trace of a febrile reaction. The very first subcutaneous dose of perlsucht toxin induces agglutination five times as pronounced as with ordinary tuberculin, even when administered intravenously and in the largest dosage. The immunization obtained with the perlsucht tuberculin is a true, natural immunization, while that obtained with human tuberculin is a pseudo-immunization. His research and observation, he claims, have established beyond question the non-identity of human and bovine tubercle bacilli. The improved differentiating stain which he recommends is applied to a dry specimen, warmed, then stained with cold Ziehl's carbol fuchsin for one to five minutes without heating in the flame, but eventually in the incubator, without any acid treatment. The superfluous fuchsin is then rinsed off with 60 per cent. alcohol, after which a small drop of Loeffler methylene blue is added to the alcohol left, which is set on fire and the specimen moved to and fro until entirely covered with the stain. It is then rinsed, dried between blotting paper and then over a flame. The bovine bacilli stain bright arterial red and seem larger, thicker and longer than by any other technic, owing to the absence of any acid treatment. Human bacilli look thin, atrophic and are a bluish, venous red or violet tint. He states further that the bactericidal action of human and bovine tuberculin is different. An infection with living bovine bacilli runs a different course from that with living human bacilli. Spengler made a subcutaneous injection of 0.5 mg. of living perlsucht bacilli in his own arm. An abscess developed without glandular involvement or general disturbance. The ulcer persisted for eight months. The agglutinating properties acquired by his serum were no higher than after injection of killed perlsucht bacilli.

62. **Diagnosis of Influenza.**—Köppen has found constantly the albumin and diazo reactions in the urine as characteristic of influenza. The reaction is probably the result of the action of the toxins.

63. **General Narrowing of Aorta.**—Apelt found this condition as the cause of fatal heart affection in two young athletes. He thinks it was acquired by excessive physical exercise.

64. **Spirochetes in Syphilis.**—Rille's findings confirm those of others in regard to the almost constant presence of the *Spirochæte pallida* in fresh syphilitic lesions. He gives the particulars of 7 cases in which it was found, and cites the communications of others, and concludes that the sum total of the results certainly points strongly to the specificity of this germ in the etiology of syphilis. He recalls that Donné, discoverer of *Trichomonas vaginalis*, described in 1837 a microorganism in syphilis which he called vibriolineola. He found it in ulcerations on the vagina and penis, and once in a leg ulcer with hospital gangrene.

65. **Id.**—Ploeger states that 100 positive single researches are now on record with only a few negative findings, and more than 50 control researches on non-syphilitic subjects with invariably negative findings.

66. **Etiology of Syphilis.**—Siegel reports that he has succeeded in inoculating rabbits and guinea-pigs with syphilis from human material introduced into the tissues of the ear passages or into a scratch in the iris. He has thus inoculated 50 rabbits with syphilis. He has further inoculated 13 monkeys with the virus obtained from the infected rabbits, with positive results in every instance. The monkeys not only presented the primary, but in time also the secondary lesions of syphilis, as he shows by the illustrations of some of them. Siegel is the discoverer of the *Cytorrhyctes luis* flagellates in syphilitic lesions, for which he has been claiming causal etiologic importance. He found these germs in the lesions of all his animals, and is convinced that their causal connection with syphilis is beyond question as these findings parallel the clinical in every instance.

67. **Determination of Diacetic Acid in Urine.**—Lindemann asserts that the urine must be acid to obtain reliable results in testing for diacetic acid. He has simplified the Riegler test and recommends the following technic: The urine is rendered acid by adding 5 drops of 30 per cent. acetic acid to 10 c.c. of the urine, and then stirring into it 5 drops of Lugol's solution (1 part iodin and 2 parts potassium iodid in 100 parts water). The whole is well shaken and 2 c.c. of chloroform are then poured on top. The layer of chloroform does not change color in case of the presence of diacetic acid, while it turns red with normal urines. The reaction is more sensitive than the ferric chlorid test. When the Gerhardt test was still negative in a mixture of 0.5 c.c. of urine containing diacetic acid with 9.5 c.c. of normal urine, the new test gave the characteristic reaction. The test was always negative with normal urine even after administration of drugs, admixture with bile pigments, alcohol, glycerin, lactic acid and creatinin. The new reaction may be abolished by boiling the urine, and also by long contact with formalin.

68. **Malakoplakia of the Bladder.**—Gierke gives the particulars of 2 cases of this affection of the bladder. He ascribes its etiology to the primary action of a cystitic urine. After the primary lesion of the epithelium, the infiltrating urine degenerates, the cells swell and become impregnated with minerals, resulting in the appearance known as malakoplakia or cystitis in patches. Four out of the 9 cases on record were accompanied by tuberculosis.

69. **Roentgen Treatment of Hypertrophied Prostate.**—Moszkowicz has already reported 3 cases of enlarged prostate treated by application of the Roentgen rays through the rectum. He here continues his reports with 6 new cases. Unmistakable benefit was derived in every instance. The effect was most rapid and pronounced in the cases in which the anuria was of recent occurrence. The gratifying results and the harmlessness of the procedure commend it for extensive application, possibly supplemented by the action of radium in the urethra. In all the cases three sittings of from ten to eighteen minutes each had a pronounced influence on the enlarged organ and on the symptoms. The prostate subsided in size and micturition became more or less normal. In 3 of the cases the patients exhibited symptoms of arteriosclerosis, with indications of angina pectoris.

71. **Treatment of Acute Suppurations with Bier's Passive Hyperemia.**—Derlin relates the history of 2 cases of severe phlegmon of a tendon sheath and one of acute traumatic osteomyelitis of the humerus. All were treated according to Bier's directions by applying a tourniquet to the limb above until a "fiery red edema" had developed. The redder the parts the more violent the inflammation. The beneficial results were remarkable, he reports, and the lesions healed with trifling loss of tissue.

73. **Etiology of Croupous Pneumonia.**—Schottmüller describes a *Streptococcus mucosus* which he found constantly and in pure cultures in his total of 6 cases of croupous pneumonia.

74. **Pathology of the Connective Tissue.**—Vogel tabulates 124 cases of flatfoot, scoliosis, varices, hernias, hemorrhoids, pendulous abdomen, prolapse of uterus, rectum or intestines and emphysema, genu valgum and coxa vara. His tables show that several of these various affections are liable to befall the same individual. His argument is to the effect that they are all manifestations of some congenital anomaly in the connective tissue system. The entire stratum fibrosum is more or less abnormal in such persons, and the physician should examine them for other manifestations of this anomaly when he observes any one of the above affections. Some of the patients cited had six, but three or four was the average.

75. **Inflammatory Lipoma in Knee or Foot.**—Gangele has had occasion to observe several cases of the fat tissue tumors to which Hoffa recently called attention as a frequent consequence of slight trauma or inflammation. They are liable to occur in any joint and to cause severe disturbances. Gangele describes the cases of four patients promptly cured by surgical intervention.

76. **Aspiration Treatment of Purulent Rhinitis.**—Sondermann reiterates his former assertions in regard to the great value of aspiration as a means of treating purulent rhinitis. He has devised an apparatus for the purpose, and he says that it is amazing to see the quantities of purulent secretions which the aspiration removes. In many cases it is evident that some of the secretion must come from the accessory cavities. He has found that the aspiration treatment is equally effective for adults and for children, and that the latter readily learn to use the aspirator themselves. He advises its use four or five times a day in severe cases and morning and night in the mild ones.

81. **Finsen's Disease.**—During the entire time of his principal life work Finsen suffered from severe chronic hyperplastic peritonitis with exudation. He studied to keep the ascites under control and took copious notes of the course and details of the disease, which are here reproduced in detail: Born on the Faroe Islands, near Iceland, at 2 years he had meningitis; at 13 pneumonia; at 16 jaundice; at 20 nephritis, and at 21 measles. From childhood he always had a slight blue and cold look, as if half frozen. At 23 the first digestive disturbances appeared, ascribed at first to gastric catarrh, but later

diagnosed as chronic peritonitis. The symptoms and autopsy findings were those of the affection known variously as "iced liver," "pericarditic pseudo-cirrhosis of the liver" or "chronic hyperplastic peritonitis with exudation." The ascites is the chief clinical manifestation, and the chronic peritonitis the predominant pathologic anatomic finding. In a case reported by Rumpf the patient was tapped 301 times, but Finsen required puncture only 18 times, as he kept the ascites under good control. The "iced" aspect involved not only the peritoneum and liver, but also the spleen, and there were evidences of a very old, adhesive calcified pericarditis. He experimented with "dry diet" as a means to reduce the ascites, and found that two or three days after reducing the intake of fluids to 325 or 400 gm. the diuresis increased remarkably and greatly reduced the ascites. Later the diuresis was not so easily influenced as at first and the restriction of fluids had to be still stricter to accomplish the same result. To enhance the diuretic action of the "dry diet" he took purgatives, finding that 7 gm. of calcined magnesia in 100 gm. oatmeal porridge eliminated from 700 to 800 gm. fluid by the intestines while the kidneys excreted about the same amount. Distaste for the magnesia led to substitution of ammonium chlorid or sodium sulphate later. The drug always had to be used in connection with restriction of intake of fluids or the diuresis was insignificant. By these means Finsen was able to keep the ascites under control for several years. He was convinced that he would have been incapacitated for work many times in the course of those years if he had trusted to punctures and ordinary treatment. In 1900 he began to study the influence of salt on his condition, and continued for months his careful research on the metabolism of salt in comparison with other physical findings. His tabulated data are a valuable contribution to the literature on the subject. He found that the largest proportion of salt was eliminated when he was on a salt-free diet. Also that ingestion of a considerable amount of salt seemed to have a depressing influence on his capacity for eliminating it. The high specific gravity of the ascitic fluid and large proportion of albumin indicated that his ascites was an inflammatory exudate and not a mere effusion. There was no compression of the portal vein and no indications of tuberculosis.

83. **Steam Cauterization of Uterus.**—Baisch reviews the present status of vaporization of the uterus, the method of treatment introduced by Sneguireff some years ago and advocated especially by Pinkus. His conclusions are that the method is unreliable, the action sometimes being too profound and again too slight, the thickness of the mucosa being a variable quantity. The success of the procedure depends on chance. The only indication which he accepts for vaporization is the preclimacteric uncomplicated hemorrhage in chronic metro-endometritis. In this condition it may answer the same purpose as the otherwise necessary hysterectomy, and hence may be regarded as a valuable measure in these circumstances. It should never be attempted, however, until after a malignant process has been certainly excluded. Zestocausis is a modified form of vaporization; the steam is kept enclosed in a metal catheter and produces a kind of weak thermocauterization. The literature cited embraces 57 articles.

84. **Puncture of the Brain.**—Weintraud reports 4 cases in which he bored through the skull with an electric drill and punctured through the opening thus made. In the first case a woman of 53 had presented indications of sensory aphasia and facial paralysis. She [illegible]ose, and the skull was drilled and punctured [illegible] and fluid was aspirated. The lesion pr[illegible] tumor at this point. If it had been an abs[illegible] have had a direct therapeutic effect. In [illegible] woman had attacks of vomiting, finally [illegible] choked disc. The right lateral v[illegible] times and the headache was alwa[illegible] tarded pulse returned to its forme[illegible] the choked disc did not retrogress. [illegible] did not seem to be very high in this [illegible] puncture was remarkable. The fi[illegible] brain substance must be already injure[illegible] when signs of compression of the brain [illegible] another case puncture of the lateral ventricle for symptoms of a brain tumor failed to relieve. Not a drop of fluid could be aspirated and nothing was found postmortem to explain the symptoms. Weintraud thinks that the affection responsible for the symptoms must have been a swelling of the brain, and that negative puncture in such a case should be accepted as an important aid in the diagnosis of this condition. He urges more general adoption of exploratory drilling and puncture, confident that in many cases it may bring relief and even cure. The latter might readily occur in case of a solitary tubercle already in retrogression but becoming dangerous by the accompanying internal hydrocephalus.

85. **Febrile Affection of Liver in a Syphilitic.**—The possibility of an isolated febrile syphilitic enlargement of the liver has been discussed considerably in the last few months. Reye here describes a case in which the symptoms suggested abscess formation in the liver in a syphilitic, but they all vanished under specific mixed treatment. The patient had been infected with syphilis eight or nine years previously.

86. **Intravenous Medication.**—Mendel is convinced that the intravenous route is free from danger for the patient and that with correct technic and appropriate drugs, it is destined to prove an important factor in the renaissance of pharmacodynamic therapy. His experience with the salicylates and thiosinamin administered intravenously has been extremely favorable.

88. **Disinfection of the Tonsils.**—Zeuner recommends pastilles made of guaiac flavored with some aromatic substance, to be used as a disinfectant and in treatment of the tonsils. Whenever there are any indications of sore throat one of these pastilles slowly dissolved in the mouth will be found very useful to avert further trouble and to cure the pathologic tendency of the tonsils.

89. **Congenital Stenosis of the Pylorus.**—Loew relates a case of this condition in which remarkable improvement followed the administration of a tablespoonful of an alkaline mineral water after eating. This [illegible]y neutralized the hyperacid secretions and thus abo[illegible] condition causing the reflex stenosis.

Later the diuresis was not so easily influenced as at first and the restriction of fluids had to be still stricter to accomplish the same result. To enhance the diuretic action of the "dry diet" he took purgatives, finding that 7 gm. of calcined magnesia in 100 gm. oatmeal porridge eliminated from 700 to 800 gm. fluid by the intestines while the kidneys excreted about the same amount. Distaste for the magnesia led to substitution of ammonium chlorid or sodium sulphate later. The drug always had to be used in connection with restriction of intake of fluids or the diuresis was insignificant. By these means Finsen was able to keep the ascites under control for several years. He was convinced that he would have been incapacitated for work many times in the course of those years if he had trusted to punctures and ordinary treatment. In 1900 he began to study the influence of salt on his condition, and continued for months his *careful research on the metabolism of salt in comparison with* other physical findings. His tabulated data are a valuable contribution to the literature on the subject. He found that the largest proportion of salt was eliminated when he was on a salt-free diet. Also that ingestion of a considerable amount of salt seemed to have a depressing influence on his capacity for eliminating it. The high specific gravity of the ascitic fluid and large proportion of albumin indicated that his ascites was an inflammatory exudate and not a mere effusion. There was no compression of the portal vein and no indications of tuberculosis.

83. **Steam Cauterization of Uterus.**—Baisch reviews the present status of vaporization of the uterus, the method of t[illegible]ment introduced by Sneguireff some years ago and advocated especially by Pinkus. His conclusions are that the method is unreliable, the action sometimes being too profound and again too slight, the thickness of the mucosa being a variable quantity. The success of the procedure depends on chance. The only indication which he accepts for vaporization is the preclimacteric uncomplicated hemorrhage in chronic metro-endometritis. In this condition it may answer the same purpose as the otherwise necessary hysterectomy, and hence may be regarded as a valuable measure in these circumstances. It should never be attempted, however, until after a malignant process has been certainly excluded. Zestocausis is a modified form of vaporization; the steam is kept enclosed in a metal catheter and produces a kind of weak thermocauterization. The literature cited embraces 57 articles.

84. **Puncture of the Brain.**—Weintraud reports 4 cases in which he bored through the skull with an electric drill and punctured through the opening thus made. In *the first case* a woman of 53 had presented indications of sensory aphasia and facial paralysis. She became comatose, and the skull was drilled and punctured at the aphasia center and fluid was aspirated. The lesion proved to be a large tumor at this point. If it had been an abscess the puncture would have had a direct therapeutic effect. In the second case a young woman had attacks of vomiting, finally accompanied by headache and choked disc. The right lateral ventricle was punctured three times and the headache was always relieved at once. The retarded pulse returned to its former state in a day or so, but the choked disc did not retrogress. The pressure in the brain did not seem to be very high in this case, but the relief from puncture was remarkable. *The findings suggest that the* brain substance must be already injured by the compression when signs of compression of the brain become apparent. In another case puncture of the lateral ventricle for symptoms of a brain tumor failed to relieve. Not a drop of fluid could be aspirated and nothing was found postmortem to explain the symptoms. Weintraud thinks that the affection responsible for the symptoms must have been a swelling of the brain, and that negative puncture in such a case should be accepted as an important aid in the diagnosis of this condition. He urges more general adoption of exploratory drilling and puncture, confident that in many cases it may bring relief and even cure. The latter might readily occur in case of a solitary tubercle already in retrogression but becoming dangerous by the accompanying internal hydrocephalus.

85. **Febrile Affection of Liver in a Syphilitic.**—The possibility of an isolated febrile syphilitic enlargement of the liver has been discussed considerably in the last few months. Reye *here describes a case in which the symptoms suggested* abscess formation in the liver in a syphilitic, but they all vanished under specific mixed treatment. The patient had been infected with syphilis eight or nine years previously.

86. **Intravenous Medication.**—Mendel is convinced that the intravenous route is free from danger for the patient and *that with correct technic and appropriate drugs*, it is destined to prove an important factor in the renaissance of pharmacodynamic therapy. His experience with the salicylates and thiosinamin administered intravenously has been extremely favorable.

88. **Disinfection of the Tonsils.**—Zeuner recommends pastilles made of guaiac flavored with some aromatic substance, to be used as a disinfectant and in treatment of the tonsils. Whenever there are any indications of sore throat one of these pastilles slowly dissolved in the mouth will be found very useful to avert further trouble and to cure the pathologic tendency of the tonsils.

89. **Congenital Stenosis of the Pylorus.**—Loew relates a case of this condition in which remarkable improvement followed the administration of a tablespoonful of an alkaline mineral water after eating. This evidently neutralized the hyperacid secretions and thus abolished the condition causing the reflex stenosis.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.
